in this hospital attendance, six months as a resident pupil. He will be required to present a certificate of having taken notes of at least six medical and surgical cases recorded under the supervision respectively of a physician and surgeon of his hospital. Three months' study of fever—which may be included in his 27 months' hospital attendance—in a hospital containing fever wards, and having taken notes of five cases of fever—viz., either typhus fever, typhoid fever, scarlet fever, small-pox, or measles. Six months' practical midwifery and diseases of women during the winter or summer of the third or the fourth year at a recognised lying-in hospital or maternity. Three months' practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy, or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist. Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council and of having been registered by that Council as a student in medicine. Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than 15 days prior to such registration, except in the subjects of physics or biology. This registration is not undertaken by the Hall. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

UNIVERSITY OF BRUSSELS.

British and other practitioners holding registrable qualifications are admitted to the examination for the Doctorate of the University of Brussels without further curriculum. It is essentially a *practitioner's* examination and is separate from that intended for the Belgian students who take up the medical curriculum of the University. The fees are—For matriculation, £8 12*s.*; for 1st Part, £4 4*s.*; for 2nd Part, £4 8*s.*; for 3rd Part, £4 8*s.*; for legalisation of diploma, 8*s.*—total, £22. Candidates who have paid in advance the fees for the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; those who fail in the second recover the fees paid for the third examination. Unsuccessful candidates are allowed to come up again three months after rejection on payment of examination fees only, provided this second appearance be in the course of the same academical year (October 1st to June 30th), otherwise they must renew the payment of the matriculation fee of £8 12*s.* The examination consists of three parts, viz.—1st Part: General Medicine; Materia Medica and Pharmacology; General Surgery; and Theory of Midwifery. 2nd Part: General Therapeutics; Pathology and Morbid Anatomy, with use of the microscope; Special Therapeutics and Medicine of Internal Diseases, including Mental Diseases; and Special Surgery. 3rd Part: Public and Private Hygiene; Medical Jurisprudence; Clinical Medicine; Clinical Surgery; examination in Operative Surgery, consisting of some of the usual operations on the dead subject—viz., Amputation, Ligature of an Artery, &c.; Ophthalmology; examination in Midwifery, consisting in obstetrical operation on the mannikin (model of pelvis); and examination in Regional Anatomy with Dissection. The time required for the three examinations seldom exceeds ten days, and is usually less. Candidates have the option of passing each part separately or of taking the three together, and the latter is the usual course; also of demanding a written examination on payment of an additional fee of one guinea for each part, a rule of which candidates rarely or never avail themselves. The examinations, which are *vivâ voce*, begin on the first Tuesday in November, December, February, May, and June. Candidates should appear with their diplomas at the Secretary's office not later than 2 P.M. on the day preceding the examination. Most of the examiners speak English and those who do not examine through the medium of an interpreter. Great importance is attached to practical knowledge, but candidates must also possess sound theoretical knowledge, the standard required varying with the subject. Pathological and other specimens are not usually shown. There are in England at present over 600 graduates holding this degree, and a British Association of Brussels Medical Graduates has been in existence for many years. Applications should be made to the Secrétariat, 14, Rue des Sols, Bruxelles.

METROPOLITAN MEDICAL SCHOOLS.[1]

WE have already mentioned that all of the metropolitan medical schools are constituent schools of the University of London, and there is under the consideration of the University a proposal to establish a central school for the teaching of the preliminary subjects of the medical curriculum. The University recognises University College and King's College as two suitable centres for such teaching and proposes their continuance as such, but has suggested to the other schools that their preliminary studies should be conducted either at one of these centres or at a new central school to be built in Kensington as a third centre. Only one school, however, has hitherto acted on this proposition—viz., that attached to St. George's Hospital. This medical school ceased to teach the subjects for the first and second examinations soon after the scheme was put forward. Many of the remaining schools have intimated to the University that they intend to continue to teach all the subjects of the curriculum, their teachers being recognised for that purpose.

ST. BARTHOLOMEW'S HOSPITAL.—The clinical practice of the hospital is large. The hospital contains 744 beds, of which 674 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley.

This hospital receives within its walls more than 7000 in-patients annually and its out-patients and casualties amount to more than 126,000 annually.

Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery in which Chief Assistants and Clinical Assistants are appointed annually. There is an Electrical Department, including X Ray, &c. Surgical operations take place every day at 1.30 P.M. and Surgical Consultations are held on Thursdays at the same hour. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical Lectures on all special subjects are also given. The visits of the physicians and surgeons are made at 1.30.

Ten house physicians and ten house surgeons are appointed annually. During their first six months of office they act as "junior" house physicians and house surgeons and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. All the appointments are now free. A residential college is attached to the hospital.

New Buildings.—The new buildings that have been recently opened comprise residential quarters for the resident staff, new casualty, medical, surgical, and special out-patient departments, new casualty wards, dispensary, and clinical lecture theatre. A new chemical laboratory has been added, available for the Medical School, and affording facilities for instruction in Public Health.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy botany physiology, comparative anatomy, materia medica, and pathological anatomy. The pathological museum i the most complete in the kingdom. There are laboratorie for chemistry, physiology, pathology, chemical pathology pharmacology, physics, public health, and biology, givin ample accommodation in every department.

Special Classes for the Final F.R.C.S. are held twice yearly *Instruction in Preliminary Science* is given to University

---

[1] For Scholarships see p. 627 et seq.

Part I. Every candidate must apply (internal students to the academic registrar and external students to the external registrar) for a form of entry on or before May 24th or Dec. 5th, which must be returned not later than June 1st for the July examination or Dec. 12th for the January examination. No fee will be charged for a first entry, but £2 will be charged for each subsequent entry. The examination will include a paper, practical work, and oral questions in Organic Chemistry.

Intermediate Examination.—The Intermediate examination in Medicine takes place twice in each year, commencing on the third Monday in January and on the first Monday in July. The subjects of the examination are Anatomy, Physiology and Histology, and Pharmacology, including Materia Medica. No candidate shall be admitted to this examination unless he have passed Part I. of the Preliminary Scientific examination at least two years previously and Part II. at least one year previously. Internal students must have completed the second and third years' course of study prescribed for them by the University and external students must produce certificates of having subsequently to having passed Part I. of the Preliminary Scientific examination been a student during two years at one or more of the medical institutions or schools recognised by this University and of having attended (1) a course of not less than 100 lectures on Anatomy; (2) a course of Dissections for not less than 12 months; (3) a course of not less than 60 lectures on Physiology; (4) courses of Experimental Physiology, Histology, and Physiological Chemistry for not less than three months each; (5) lectures and demonstrations on Pharmacology, Pharmacy, and Materia Medica for not less than three months; and (6) Practical Pharmacy for not less than two months. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination. Fee for this examination £10.

M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the last Monday in October and on the first Monday in May. No candidate will be admitted to this examination within two academic years from the date of passing the Intermediate examination. The M.B., B.S. examination under the regulations now described was held for the first time in October, 1904. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination. Every candidate must produce certificates of having passed the intermediate examination and of having subsequently attended courses of instruction in (1) Principles and Practice of Medicine, including a two months' course of instruction at a recognised Fever Hospital; (2) Clinical Methods and Physical Diagnosis; (3) Insanity; (4) Therapeutics; (5) Vaccination; (6) Principles and Practice of Surgery; (7) Operative Surgery, Surgical Anatomy, Practical Surgery, and the Administration of Anæsthetics; (8) Diseases of the Eye, Ear, and Throat; (9) Midwifery and Diseases of Women; (10) Practical Midwifery, the conduct of at least 20 Labours, and practice as a Clinical clerk in Gynæcological work; (11) Pathology and Bacteriology; (12) work of the Post-mortem room; (13) Forensic Medicine; and (14) Hygiene. He must also have attended the Medical and Surgical practice of a recognised hospital for two years and a fever hospital for two months. For internal students the above form the subjects of the fourth and fifth years of study as prescribed by the University. Candidates as external students in medicine must have been engaged in professional study during five years subsequent to matriculation and four years subsequent to passing the Preliminary Scientific Examination Part I. at one or more of the schools recognised by the University for the purpose. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The fee is £10 for each entry to the whole examination and £5 for examination or re-examination in either group. There will be no separate examination held for Honours but the list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates must have taken the degrees of M.B., B.S. not less than two years previously but for those who have taken the M.B., B.S. degrees with Honours or have done certain original work this period of delay may be reduced to one year. They may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Certain conditions have to be fulfilled in each case, varying according to the nature of the branch in question. Any candidate for the degree of M.D. may transmit to the Registrar, not less than two months before the commencement of the examination, a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners the candidate may be exempted from the written examination. The fee is £20.

Master in Surgery.—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July. Candidates must produce certificates of having taken the degrees of M.B. and B.S. not less than two years previously and of having subsequently held for at least six months a resident or non-resident Surgical hospital appointment. The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Surgery, Surgical Pathology and Anatomy, a Clinical examination, and operations on the dead body. Any candidate for the degree of M.S. may transmit to the Registrar, not later than two months before the commencement of the examination, a thesis or published work having definite relation to Surgery, and if the thesis be approved by the examiners the candidate may be exempted from the written examination in Surgery. The fee is £20.

Full details of the prescribed curricula of study, with the syllabus for each examination and the names of the recognised Internal and External Schools of the University can be obtained from the Academic Registrar, University of London, S.W.

The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by, and are paid out of the funds of, the University. 2. Recognised teachers—i.e., such as have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University and have been recognised by the Senate as conducting work of University standard. Thus in the Faculty of Medicine, although there are at present no appointed teachers, there are 401 recognised teachers belonging to the various metropolitan medical schools. In the Faculty of Science J. N. Collie, Ph D., F.R.S., and S. Smiles, D.Sc., are the appointed teachers in Organic Chemistry; Sir William Ramsay, Ph.D., F R S., and N. T. M. Wilsmore, M.Sc., are appointed teachers in General Chemistry; and A. D. Waller, M.D., F.R.S., who is Dean of the Faculty and also Director of the Physiological Laboratory, is the appointed teacher in Physiology. There are 212 recognised teachers in the Faculty of Science. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in King's College, London, and University College, London, will be found enumerated under their respective medical schools.

UNIVERSITY OF DURHAM.

One Diploma and six degrees are conferred—viz., the Diploma in Public Health and the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene. These degrees are open both to Men and Women.

For the degree of *Bachelor in Medicine* there are four professional examinations. The subjects of the First Examination are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy, Physiology, Materia Medica, Therapeutics, Pharmacology, Pharmacy. The subjects for the Third Examination are—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.

Anæsthetics: Mr. C. Carter Braine. Dental Surgery: Mr. J. F. Colyer. Forensic Medicine: Dr. Fenton. Materia Medica and Practical Pharmacy: Dr. Galloway. Midwifery: Dr. Amand Routh. Diseases of Women: Dr. T. W. Eden. Pathology: Dr. W. Hunter. Pharmacology and Therapeutics: Dr. Galloway. Anatomy: Dr. Alexander Macphail. Practical Chemistry: Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Forsyth. Practical Physiology: Mr. C. F. Myers-Ward. Public Health: Dr. H. T. Bulstrode. Toxicology: Dr. H. Forster Morley. Roentgen Ray: Dr. Ironside Bruce. Dean of the Medical School: Mr. Frederick C. Wallis.

St. George's Hospital.—This hospital contains 350 beds, of which 205 are allotted to surgical and 145 to medical cases. One ward is set apart for Diseases peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

The Winter Session commences on Oct. 1st but students can enter at any time or for any particular course. The Hospital and Medical School are situated at Hyde Park-corner and are readily accessible from all parts of London. Entrance Scholarships in Anatomy and Physiology are awarded at the commencement of each Winter Session. Prizes: The William Brown Exhibition of £100 per annum (tenable for two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £40 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital. Students are permitted to enter the wards of the hospital at any hour. Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. A large number of house office appointments are open without fee to every perpetual student of the hospital and are made strictly in accordance with the merits of the candidates. Special attention is directed to the following paid appointments, amongst others, which are open to students after they have held house office:—Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Curatorship of the Museum at £200; Assistant Curatorship at £100; Obstetric Assistantship (Resident) at £50; the post of Senior Anæsthetist at £50; the posts (2) of Junior Anæsthetists, each at £30. Great attention is paid by members of the staff to individual teaching. A number of special courses are given in which the requirements of university and other examinations receive careful attention. The following may be cited as examples:—(1) Elementary Bacteriology; (2) Advanced Bacteriology; (3) Clinical Pathology; (4) Systematic Pathology; (5) Histological Pathology and Morbid Anatomy; (6) Operative Surgery; (7) Public Health; and (8) Tropical Diseases. Special test examinations and classes are held by members of the staff for all examinations. The school possesses an Amalgamation Club, with well-fitted reading-, smoking-, and luncheon-rooms on the hospital premises. Students have the advantage of a well-filled library of medical and scientific books which is kept thoroughly up-to-date. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean. Further information may be obtained from the Dean of the Medical School. Dr. E. I. Spriggs, Dean.

Staff.—Consulting Physicians: Sir Henry Pitman, Dr. W. H. Dickinson, Dr. T. T. Whipham, and Sir Isambard Owen. Consulting Surgeons: Mr. Holmes, Mr. Pick, Mr. Hayward, Sir W. Bennett, and Mr. Marmaduke Sheild. Consulting Ophthalmic Surgeons: Mr. Brudenell Carter and Mr. Adams Frost. Consulting Aural Surgeon: Sir William Dalby. Consulting Dental Surgeon: Mr. Winterbottom. Physicians: Dr. William Ewart, Dr. H. D. Rolleston, Dr. Ogle, and Dr. Latham. Obstetric Physician: Dr. W. R. Dakin. Assistant Physicians: Dr. Collier, Dr. Spriggs, and Dr. Jex-Blake. Assistant Obstetric Physician: Dr. A. F. Stabb. Physician to the Skin Department: Dr. W. S. Fox. Physician Anæsthetist: Dr. F. Hewitt. Surgeons: Mr. C. T. Dent, Mr. G. R. Turner, Mr. F. Jaffrey, and Mr. Pendlebury. Ophthalmic Surgeon: Mr. H. B. Grimsdale. Assistant Surgeons: Mr. T. Crisp English, Mr. L. Jones, and Mr. W. F. Fedden. Surgeon to the Orthopædic Department: Mr. F. Jaffrey. Surgeon to the Throat Department: Mr. H. S. Barwell. Aural Surgeon: Mr. W. C. Bull. Dental Surgeon: Mr. N. G. Bennett. Assistant Dental Surgeon: Mr. Morley.

Guy's Hospital.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 602 beds.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical and medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical council according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The out-patient officers, who hold office for three months, attend in the out-patient department five afternoons in the week and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards and attend to all emergencies arising in the absence of the physicians. They are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons and there are four out-patient officers appointed each three months The surgeons' dressers are selected from those students who have completed their third winter session and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, four in number, are provided with board and lodging in the college free of expense. The college stands upon a site fronting the east gate of the hospital and is connected with it by a subway. The building serves as a Residential College for Students and at the same time provides accommodation for the Students' Club.

Medical and Surgical Staff.—Consulting Physicians: Sir Samuel Wilks, Bart., Dr. F. W. Pavy, Dr. P. H. Pye-Smith, Dr. J. F. Goodhart, and Dr. F. Taylor. Consulting Surgeons: Mr. Thomas Bryant, Sir H. G. Howse, Mr. W. H. A. Jacobson, and Mr. R. C. Lucas. Consulting Obstetric Physician: Dr. A L. Galabin. Consulting Physician for Mental Diseases: Dr. G. H. Savage. Consulting Aural Surgeon: Mr. W. Laidlaw Purves. Consulting Anæsthetist: Mr. Tom Bird. Consulting Ophthalmic Surgeons: Mr. C. Higgens and Mr. W. A. Brailey. Physicians and Assistant Physicians: Dr. W. Hale White, Dr. G. Newton Pitt, Sir Cooper Perry, Dr. L. E. Shaw, Dr. J. Fawcett, Dr. A. P. Beddard, Dr. H. S. French, and Dr. Hertz. Surgeons and Assistant Surgeons: Mr. C. H. Golding-Bird, Mr. Charters J. Symonds, Mr. W. Arbuthnot Lane, Mr. L A. Dunn, Sir Alfred Fripp, C.B., K.C.V.O., Mr. F. J. Steward, Mr. Fagge, and Mr. R. P. Rowlands. Obstetric Physicians: Dr. P. Horrocks and Mr. J. H. Targett. Assistant Obstetric Physician: Mr. G. Bellingham Smith. Ophthalmic Surgeons: Mr. H. L. Eason and Mr. A. W. Ormond. Physician in Charge of Skin Department: Sir Cooper Perry. Physician for Mental Diseases: Dr. M. Craig. Surgeon in Charge of Throat Department: Mr. F. J. Steward. Surgeon in Charge of Aural Department: Mr. C. H. Fagge. Dental Surgeons: Mr. W. A. Maggs, Mr. R. Wynne Rouw, Mr. H. L. Pillin, and Mr. M. F. Hopson. Anæsthetists: Mr. G. Rowell, Dr. H. F. Lancaster, Mr. C. J. Ogle, Mr. P. Turner, Dr. D. Forsyth, Mr. W. M. Mollison, Mr. A. R. Thompson, and Mr. R. Davies-Colley. Medical Registrars and Tutors: Dr. H. C. C. Mann and Mr. H. C. Cameron. Obstetric Registrar and Tutor: Mr. R. Davies-Colley. Surgical Registrars and Tutors: Mr. G. Hamilton and Mr. A. S. Bankart. Actino-Therapeutic Department: Dr. C. E. Iredell. Radiographers: Mr. E. W. H. Shenton, Dr. A. E. Jordan, and Dr. C. J. Morton. Bacteriologist to the Hospital: Dr. W. H. Eyre. Resident Surgical Officer: Mr. E. C. Hughes, M.C. Hon. Librarian, Wills Library: Dr. L. E. Shaw. Lying-in Charity: Mr. Targett and Mr. Bellingham Smith Dean of the Medical School: Dr. H. L. Eason. Warden of the College: Mr. W. M. Mollison, M.C.

Lecturers and Demonstrators.—Clinical Medicine: the Physicians and Assistant Physicians. Clinical Surgery: the Surgeons and Assistant Surgeons. Medicine: The Physicians. Practical Medicine: Dr. Bell Walker and Mr.

of some science directly relative to medicine. The examination will consist of an examination in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate. It will be partly written, partly practical.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; and (6) Pathology and Bacteriology.

Professors—Physics: E. Rutherford, M.A., D.Sc., F.R.S. Chemistry: H. B. Dixon, M.A., F.R.S. Organic Chemistry: W. H. Perkin, M.A., D.Sc., F.R.S. Zoology: S. J. Hickson, D.Sc., F.R.S. Botany: F. E. Weiss, D.Sc. Physiology: W. Stirling, M.D., D.Sc. Anatomy: A. H. Young, LL.D. Materia Medica: R. B. Wild, M.D. Comparative Pathology and Bacteriology: A. S. Delépine, M.Sc. Pathology: J. Lorraine Smith, M.D. Medicine: Graham Steell, M.D. Systematic Surgery: G. A. Wright, F.R.C.S. Clinical Surgery: F. A. Southam, F.R.C.S. Obstetrics and Gynæcology: Sir W. J. Sinclair, M.D. Forensic Medicine: J. Dixon Mann, M.D.

Communications should be addressed to the Registrar, The University, Manchester.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of registration with the General Medical Council. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other school or schools of medicine recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations. For the present the University will recognise any one of the following examinations, in lieu of its own Matriculation, in the case of medical students, provided always that such examination shall have included the subjects of English, Latin, Mathematics, and any one of the following: Greek, French, German, or any other modern foreign language, together with Chemistry or Experimental Mechanics, or some other branch of Experimental Physics, and that all the subjects have been passed at one examination: (*a*) the previous examination of the University of Cambridge; (*b*) responsions of the University of Oxford; (*c*) the Preliminary or Matriculation Examination of any recognised University; (*d*) the (Higher) Certificate of the Oxford and Cambridge Examinations Board; (*e*) the Oxford or Cambridge Junior Local Examinations; with First or Second Class Honours, or with Distinctions in two subjects, which may be either languages or mathematics; (*f*) the Oxford or Cambridge Senior Local Examination. A Matriculation Examination will be held on Sept. 23rd, 1907, and succeeding days. First Examination.—Chemistry and Physics and Elementary Biology. Second Examination.—Anatomy and Physiology. Third Examination.—Pathology and Bacteriology, Materia Medica and Practical Pharmacy. Fourth Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, and Public Health. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Gynæcology, Therapeutics, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital and lunatic asylum. Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of [illegible] *nd Master of Surgery.*— [illegible] e date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both.

Candidates for either of these degrees will be required to comply with the following regulations. Every candidate for the degree of M.D. shall present a thesis embodying observations in some subject embraced in one of the departments of the medical curriculum enumerated below, and in addition he will be required to pass a general examination in Principles and Practice of Medicine. It will be in the power of the Board of Examiners to exempt a candidate whose thesis is of exceptional merit from any part of these examinations.

A thesis may be presented in any of the following departments of study: (*c*) Anatomy, including Comparative Anatomy, (*b*) Physiology, (*c*) Human or Comparative Pathology, (*d*) Bacteriology, (*e*) Pharmacology, (*f*) Therapeutics, (*g*) Medicine, (*h*) Mental Diseases, (*i*) Preventive Medicine or Public Health, (*j*) Toxicology, (*k*) Legal Medicine, (*l*) Midwifery.

Candidates for the degree of Ch.M. are required to comply with the following regulations:—At the end of one year from the date of having passed the final M.B., Ch.B. Examination candidates will be eligible to present themselves for the higher degree of Master of Surgery. Candidates for this degree will be required to comply with the following regulations: 1. Every candidate shall present a thesis, embodying observations in some subject embraced in one of the departments of the medical curriculum enumerated below; in addition the candidates will be required to pass a general examination in Principles and Practice of Surgery and to perform operations on the cadaver. 2. It will be in the power of the board of examiners to exempt a candidate whose thesis is of exceptional merit from any part of these examinations. 3. The candidate may be examined in that department of the medical curriculum from which the subject of his thesis is chosen and the examiners may require to see the notes of original observations on which the thesis is based, (*a*) Surgery, (*b*) Pathology, (*c*) Bacteriology, (*d*) Gynæcology, (*e*) Ophthalmology.

Degree in Public Health.—For the regulations for this degree and for the diploma in the same subject see p. 656.

Fees.—Matriculation, £2; First Examination, £2; Second Examination, £2; Third Examination, £2; Fourth Examination, £2; Final Examination, £2; Admission Fee to degrees of M.B., Ch.B., £6: M.D. or Ch.M., £2; Admission Fee to degree of M.D. or Ch.M., £8.

Professors—Physics: J. H. Poynting, Sc.D., F.R.S. Chemistry: P. H. Frankland, Ph.D., F.R.S. Zoology: T. W. Bridge, Sc.D., F.R.S. Botany: W. Hillhouse, M.A. Medicine: R. Saundby, M.D., and A. H. Carter, M.D. Surgery: Bennet May, F.R.C.S., and G. Barling, F.R.C.S. Anatomy: A. Robinson, M.D. Physiology: E. W. Wace Carlier, M.D. Elementary Biology: T. W. Bridge, Sc.D., F.R.S. Therapeutics: A. Foxwell, M.D. Forensic Medicine: J. T. J. Morrison, F.R.C.S. Hygiene and Public Health: A. Bostock Hill, M.D. Midwifery: E. Malins, M.D. Gynæcology: J. W. Taylor, F.R.C.S. Pathology: R. F. C. Leith, F.R.C.P. Edin. Lunacy and Mental Disease: E. B. Whitcombe, M.B. Operative Surgery: Jordan Lloyd, F.R.C.S. Ophthalmology: Priestley Smith, F.R.C.S.

UNIVERSITY OF LIVERPOOL.

The student must pass either (1) the University Matriculation Examination, or (2) the Final Examination for Graduation in Arts of any university in Great Britain and Ireland, or (3) the Matriculation Examination of the University of London, or (4) the Higher Certificate Examination of Oxford and Cambridge Joint Board, or (5) the Senior Local Examination of Oxford or Cambridge, with honours, or (6) some other examination of equal standard accepted by the Joint Matriculation Board. The course of professional study, subsequent to passing the Matriculation Examination and having been registered as a medical student, extends over five years. The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in has his offices in the College, enabling the candidates to attend daily to work under his supervision. These courses are recognised both by the Universities of Oxford, Cambridge, London, &c., and by the Examining Board in England. A reduction of 15 guineas is made from the perpetual fee to the sons of members of the profession. The new laboratories and class-rooms for Bacteriology, Vaccino-therapy, Public Health, Operative Surgery, Chemistry, and Biology are now in full use. The new Clubs Union Rooms, Garden, and Fives Court are now open. The Clubs Union Athletic Ground is within easy reach of the hospital. The Metropolitan and other railways have stations close to the hospital and the college.

Staff.—Consulting Physicians: Dr. Hughlings Jackson and Sir Stephen Mackenzie. Consulting Surgeons: Mr. Hutchinson, Mr. Couper, Mr. McCarthy, Sir Frederick Treves, Bart., and Mr. Tay. Consulting Obstetric Physician: Dr. Herman. Physicians: Dr. Francis Warner, Dr. Percy Kidd, Dr. Frederick J. Smith, Dr. W. J. Hadley, Dr. Bertrand Dawson, Dr. Henry Head, and Dr. Robert Hutchison. Assistant Physicians: Dr. Lewis Smith, Dr. Wall, Dr. Grünbaum, and Dr. Thompson. Surgeons: Mr. C. W. Mansell-Moullin, Mr. Hurry Fenwick, Mr. F. S. Eve, Mr. J. Hutchinson, jun., Mr. T. H. Openshaw, Mr. H. P. Dean, and Mr. P. Furnivall. Assistant Surgeons: Mr. H. Barnard, Mr. Rigby, Mr. Sherren, and Mr. Lett. Obstetric Physician: Dr. Lewers. Assistant Obstetric Physician: Dr. Andrews. Physician to the Skin Department: Dr. Sequeira. Consulting Dental Surgeon: Mr. Barrett. Consulting Anæsthetist: Dr. Hewitt. Ophthalmic Surgeons: Mr. A. B. Roxburgh and Mr. Lister. Surgeon to the Throat Department: Dr. Lambert Lack. Aural Surgeon: Mr. Hunter Tod. Medical Officer in charge of the Electrical Department: Dr E. R. Morton. Physician in charge of the Photo-therapy Department: Dr. Sequeira. Analyst to the Hospital: Mr. Hugh Candy. Bacteriologist to the Hospital: Dr. W. Bulloch. Dental Surgeons: Mr. Dolamore and Mr. Farmer. Anæsthetists: Dr. Probyn-Williams, Mr. Hilliard, and Mr. Clapham.

Lecturers.—Medicine: Dr. Percy Kidd and Dr. Hadley. Clinical Medicine: the Physicians and Assistant Physicians. Surgery: Mr. C. W. Mansell-Moullin. Clinical Surgery: the Surgeons and Assistant Surgeons. Anatomy: Dr. A. Keith. Physiology: Dr. Leonard Hill, Mr. J. A. Craw, Mr. Greenwood, and Mr. Flack. Chemistry: Mr. F. J. M. Page and Mr. Hugh Candy. Pathology—General and Surgical: Dr. W. Bulloch. Midwifery and Diseases of Women: Dr. Lewers. Clinical Obstetrics: The Obstetric Physicians. Practical Obstetrics: Dr. Andrews. Forensic Medicine—(1) Public Health: Dr. J. C. Thresh; and (2) Medical Jurisprudence and Toxicology: Dr. F. J. Smith. Public Health and Sanitary Science: Dr. W. Bulloch, Dr. John C. Thresh, and Mr. F. J. M. Page. Mental Diseases: Dr. J. Kennedy Will. Materia Medica and General Therapeutics: Dr. Francis Warner and Dr. Grünbaum. Biology: Mr. G. P. Mudge. Experimental Physics: Mr. F. J. M. Page, Mr. Hugh Candy, and Mr. Griffith. Ophthalmic Surgery: Mr. A. B. Roxburgh. Diseases of the Throat: Dr. Lambert Lack. Aural Surgery: Mr. Hunter Tod. Anatomy and Pathology of the Teeth: Mr. H. Dolamore and Mr. F. M. Farmer. *Practical Anatomy:* Dr. Arthur Keith, Mr. Howard, and Mr. Patterson. Practical Physiology and Histology: Dr. Leonard Hill, Mr. Craw, Mr. Greenwood, and Mr. Flack. Foods and Dietetics: Dr. R. Hutchison. Practical Chemistry: Mr. F. J. M. Page and Mr. Hugh Candy. Operative Surgery: Mr. H. P. Dean. Demonstrators of Morbid Anatomy: Dr. F. J. Smith, Dr. W. J. H. Hadley, Dr. Dawson, and Dr. Lewis Smith. Bacteriology: Dr. W. Bulloch and Mr. Twort. Pathological Histology: Dr. W. Bulloch. Inoculation Department: Dr. Western. Therapeutic Electricity and Radiography: Dr. A. E. Morton. Anæsthetics: Dr. R. J. Probyn-Williams. Elementary Clinical Medicine: Dr. Lewis Smith, and Dr. Grünbaum. Medical Tutor: Dr. Wall. Elemental Clinical Surgery: Mr. H. M. Rigby and Mr. J. Sherren. Surgical Tutor: Mr. Sherren. Obstetric Tutor: Dr. R. D. Maxwell. As Emeritus Professor of Surgery Mr. Hutchinson will give in the Summer Session, and Sir Frederick Treves, Bart., will give in the Winter Session a course of lectures in Clinical Surgery. The special subjects and the dates will be announced in due course. Dr. Hewitt, as Emeritus Lecturer on Anæsthetics, will give a course of lectures during the first half of the Winter Session. Warden: Mr. Munro Scott.

ST. MARY'S HOSPITAL.—The hospital contains 281 beds exclusive of the New Wing which, when opened, will increase the number to 341. The number of in-patients treated during 1906 was 4298. The number of out-patients was 24,456 with 23,063 casualty cases, a total of 47,519. The situation of the hospital and Medical School in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it exceptionally convenient for students' rooms, a register of which is kept by the authorities for the use of students.

Laboratories, &c.—The Medical School provides for the entire curriculum. Special laboratories are in use for Biology, Chemistry, and Physics, a series of lecture theatres and laboratories for anatomy and physiology, and a spacious and well-lighted dissecting-room. The Pathological Department is under the direction of Sir Almroth Wright, F.R.S., and during the present year a block of consulting-rooms and laboratories in the New Wing of the Hospital has been equipped for the department of Therapeutic Inoculation to meet the increased amount of work in that department. A special laboratory is provided for the study of chemical pathology.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, and four obstetric officers are appointed in each year and receive board and lodging in the hospital. Two resident anæsthetists are appointed in each year and receive a salary at the rate of £100 per annum, with board and lodging. Two casualty house surgeons are appointed in each year upon the same conditions. Several assistants in the department of Therapeutic Inoculation are appointed annually at salaries of £100 per annum and upwards. In addition to the above, the senior appointments, medical and surgical registrar, casualty physician, demonstrator of anatomy, physiology, and biology are made annually.

Clubs, &c.—The amalgamated clubs include all the various athletic clubs, as well as the rifle club, medical society, &c. There is a students' club on the Hospital premises, the membership of which is included in the amalgamated clubs. The athletic clubs' ground (eight acres) is situated at North Kensington and can be reached in 20 minutes from the Medical School. It consists of Rugby and Association football grounds, tennis courts, and a large cricket pitch.

Special Tuition.—In addition to systematic courses of lectures and demonstrations special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford, Cambridge, and London, and for the Primary and Final F.R.C.S.

Preliminary Scientific Course.—Special classes, including lectures and laboratory work, are held throughout the year under recognised teachers of the *University of London.*

The composition fee for full students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 60 guineas (£63) paid in one sum or by payment of two annual instalments of 35 guineas (£36 15*s.*) and 30 guineas (£31 10*s.*) respectively. University students who have not completed their examination in Anatomy and Physiology pay an annual fee of 25 guineas (£26 5*s.*) until they have passed these examinations, and then pay the composition fee. Separate courses of lectures, laboratory work, or hospital practice may be taken. The School Calendar and full information can be obtained from the Secretary, *St. Mary's Hospital Medical School*, Paddington, W.

Staff.—Consulting Physicians: Dr. Cheadle and Dr. Lees. *Consulting* Surgeons: Mr. A. T. Norton, Mr. Edmund Owen, Mr. *Herbert Page*, Mr. G. P. Field (*Aural*), Sir G. Anderson Critchett (Ophthalmic), Mr. Malcolm Morris (Skin), and Mr. Morton Smale (Dental). Physicians: Dr. Sidney Phillips, Dr. A. P. Luff, and Dr. H. A. Caley. Surgeons: Mr. A. J. *Pepper*, Mr. J. Ernest Lane, and Mr. H. Stansfield Collier. Physicians in charge *of Out-Patients*: Dr. Wilfred Harris, Sir John Broadbent, and Dr. W. H. Willcox. Surgeons in Charge of Out-Patients: Mr. V. Warren Low, Mr. W. H. *Clayton-Greene*, and Mr. Maynard Smith. Physician-Accoucheur: Dr. Montagu Handfield-Jones. *Physician*-Accoucheur in charge of *Out-Patients*: Dr. W. J. Gow. Physician in charge of Children's Department: Dr. Sidney Phillips. *Ophthalmic* Surgeon: Mr. H. E. Juler. Assistant Ophthalmic Surgeon: Mr. Leslie Paton. *Physician* to the

A candidate for the degrees of M.B., Ch.B., shall produce certificates that he will have attained the age of 21 years on the day of graduation; that he has pursued the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his registration as a medical student by the General Medical Council, three of such years at least having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the First Examination.

The First Examination.—The subjects of examination are *chemistry, physics, and biology*. The examination is divided into two parts, A (chemistry and physics) and B (biology), and candidates may pass in each part separately. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and registration as a medical student, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology, for one year each.

The Second Examination.—The subjects of examination are anatomy, physiology, materia medica, and pharmacy. The examination is divided into two parts, A (anatomy and physiology) and B (materia medica and pharmacy), and candidates may pass in either part separately. Candidates must have completed the third winter session of professional study, must have passed the first examination, and must have attended (1) lectures on anatomy and dissections during two winter sessions and one summer session; (2) lectures on physiology during two winter sessions, practical physiology during two winter sessions, and histology during one summer session; and (3) materia medica and pharmacy for three months.

The Third or Final Examination.—The subjects of examination are divided into two parts—namely, A (forensic medicine and toxicology, public health, and pathology and morbid anatomy) and B (medicine, including pharmacology and therapeutics, mental diseases, and diseases of children, surgery, obstetrics, and gynæcology). Candidates may present themselves for examination in both parts on the same occasion or separately, but Part A may not be passed before the completion of the fourth year of study. Candidates for the whole examination or for Part B must have completed the fifth year of study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates for the degree of Ch.M. must have passed the examination for the degrees of M.B., Ch.B at least one year previously and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution, affording full opportunity for the study of Practical Surgery.

The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

Professors—Physics: W. M. Hicks, Sc.D., F.R.S. Chemistry: W. Palmer Wynne, D.Sc., F.R.S. Biology: Alfred Denny, F.L.S. Anatomy: C. J. Patten, M.D. Physiology: J. S. Macdonald, B.A. Medicine: D. Burgess, M.A., F.R.C.P. Materia Medica, &c.: W. T. Cocking, M.D. Surgery: R. J. Pye-Smith, F.R.C.S. Pathology: J. M. Beattie, M.D. Midwifery: R. Favell, M.R.C.S. Ophthalmology: Simeon Snell, F.R.C.S. Public Health: H. Scurfield, M.D., D.P.H.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of *Bachelor of Medicine* is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

A diploma in Tropical Medicine and Hygiene (D.T.M. and H.) is granted to graduates in Medicine and Surgery of the University of not less than six months' standing. The course of study includes (1) Practical Bacteriology; (2) Diseases of Tropical Climates; (3) Tropical Hygiene; (4) a Practical Course in Medical Entomology and Protozoology and Venomous Animals; and (5) a Course of Clinical Instruction in Tropical Diseases. Any two of these courses may be taken under Extra-academical Teachers and exemption from the latter course may be granted to those graduates who have been engaged for a period of at least 12 *months in the treatment of Tropical Diseases* in any tropical or subtropical country. The examinations for the diploma, which will embrace all the foregoing subjects, are held in January and July of each year.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German: Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months. These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures. A similar course of clinical medicine during a course or courses extending over not less than nine months is required. The candidate must have attended a course of instruction in Mental Diseases given by the University Lecturer, or by a recognised Teacher, consisting of not less than six Class-room meetings for lectures and demonstrations and ten meetings in the Wards of a recognised Asylum for the insane. The candidate must have attended a course of 25 meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. The candidate must have attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries. *He must* have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital for a period of six months in each case; and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary, Post-mortem Examinations, Fevers, Diseases of the Eye, Operative Surgery, and one of the three following, viz.—*Diseases of Children*; Diseases of the Larynx, Ear, and Nose; and Diseases of the Skin, or such other special departments as may from time to time be determined. The candidate must have attended, under the superintendence of a registered medical practitioner, 12 cases of labour, or such additional number as *the* Senatus, with the sanction of the University Court, may from time to time determine; or have attended for three months the *practice* of a lying-in hospital, or of the maternity department of a general hospital or other public charitable institution and have conducted personally six or such an additional *number of cases* of labour as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination.

officers are appointed every three *months* and *hold* office for *six months*. They are provided with rooms and commons in the hospital free of expense. Clinical assistants to all the special departments are appointed at the same intervals and for the same periods; they are non-resident. A resident assistant physician and a resident assistant surgeon, at a salary of £100 each, are appointed biennially; also four hospital registrars (medical, surgical, obstetric, and ophthalmic), the two former receive a salary of £100 and the two latter £50. An assistant in the clinical laboratory, at a salary of £100 per annum, and an assistant pathologist, at a salary of £125, are from time to time appointed. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third year's work. The accident dressers are provided with board and lodging during their periods of special duty. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn for three weeks on maternity duty under proper supervision, and is practically instructed in the administration of anæsthetics by one of the hospital anæsthetists. On completion of his term as clerk or dresser he is expected to fill appointments in one or more of the special departments. In their earlier years of study students are selected as assistants to the lecturers in the preliminary and intermediate subjects. The Medical School is fully equipped for the teaching of all subjects of the curriculum. A fine museum and large library are at the disposal of the students. There are three lecture theatres, an unusually large and well-ventilated dissecting-room, and special laboratories for biology, chemistry, physics, physiology, and pathology. The post-mortem room, where demonstrations are given every day, is ventilated by the electric fan and provided with cold storage. The Students' Club comprises a spacious restaurant and magnificent smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The athletic ground of the Amalgamated Clubs is over nine acres in extent and is easily accessible from Waterloo Station. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. There is a special course for the Diploma in Public Health. The hospital is easily accessible from all parts. It is close to the Waterloo and Westminster Bridge Stations (L. & S.W., Bakerloo, and District Railways). Electric trams which pass the doors connect it with all parts of South London. A register of lodgings and a list of medical men and others who are willing to receive boarders is kept by the secretary, Mr. G. Q. Roberts, who will give any further information required.

Fees.—The annual composition fee is 30 guineas—in addition to a fee on entrance. Post-graduate study is afforded to qualified practitioners by a joint ticket which admits to the practice of 14 hospitals (general and special) on terms which may be ascertained from the secretary.

For a list of scholarships and prizes see p. 631.

Staff.—Consulting Physicians: Dr. Harley and Dr. Payne. Consulting Surgeon: Mr. S. Jones. Consulting Obstetrical Physicians: Dr. Gervis and Dr. Cullingworth. Consulting Ophthalmic Surgeons: Mr. Liebreich and Mr. Nettleship. Consulting Anæsthetist: Mr. W. Tyrrell. Physicians: Dr. Sharkey, Dr. Acland, Dr. Hawkins, Dr. Mackenzie, and Dr. Turney. Surgeons: Mr. Clutton, Mr. Pitts, Mr. G. H. Makins, C.B., Mr. Battle, Mr. Ballance, and Mr. Robinson. Physicians to Out-patients: Dr. Perkins, Dr. Colman, Dr. Box, and Dr. Russell. Surgeons to Out-patients: Mr. C. S. Wallace, Mr. E. M. Corner, and Mr. Sargent. Obstetrical Physician: Dr. Tate. Obstetrical Physician to Out-patients: Dr. Fairbairn. Ophthalmic Surgeon: Mr. Lawford. Ophthalmic Surgeon to Out-patients: Mr. Fisher. Physician for Diseases of Children: Dr. Box. Surgeon for Diseases of Children: Mr. P. W. G. Sargent. Surgeon for Diseases of the Throat: Mr. H. B. Robinson. Physician for Diseases of the Skin: Dr. E. Stainer. Surgeon for Diseases of the Ear: Mr. Ballance, with Mr. Marriage in charge of Out-patients. Dental Surgeons: Mr. J. G. Turner and Mr. G. L. Bates. Resident Assistant Physician: Dr. Dean. Resident Assistant Surgeon: Mr. J. E. Adams. Anæsthetists: Mr. H. Low, Dr. Bevan, Mr. Mennell, and Dr. Hedley. Pharmaceutist: Mr. J. A. Jennings. Curator of Museum: Mr. S. G. Shattock. Director of Laboratories: Mr. Dudgeon. Superintendent of X Ray Department: Dr. Greg.

Lecturers and Demonstrators.—Anatomy: Mr. F. G. Parsons, with Mr. P. W. G. Sargent and Mr. C. A. R. Nitch. Chemistry: Dr. Le Sueur. Physiology: Dr. J. B. Leathes. Biology: Mr. T. G. Hill. Pathology and Bacteriology: Mr. Shattock and Mr. Dudgeon. Surgery: Mr. Makins and Mr. Ballance. Medicine: Dr. Sharkey and Dr. Hawkins. Practical and Operative Surgery: Mr. Battle, Mr. Robinson, and Mr. Wallace. Comparative Anatomy: Mr. Parsons. Applied Anatomy: Dr. Box. Anæsthetics: Mr. Tyrrell and Dr. Low. Physics: Mr. Brinkworth. Clinical Medicine: The Physicians. Clinical Surgery: The Surgeons. Midwifery and Diseases of Women: Dr. Tate and Dr. Fairbairn. Diseases of the Eye: Mr. Lawford. Pharmacology and Therapeutics: Dr. Dixon. Throat Disease: Mr. H. B. Robinson. Physiological Demonstrator: Mr. Mavrogordato. Obstetrical Demonstrators: Dr. Fairbairn and Dr. Hedley. Elementary Clinical Medicine: Dr. Perkins, Dr. Colman, Dr. Box, and Dr. Russell. Surgical Classes: Mr. Wallace, Mr. Corner, Mr. Fisher, and Mr. Shattock. Forensic Medicine and Toxicology: Dr. Colman and Dr. Haas. Mental Diseases: Dr. R. Percy Smith. Public Health: Dr. E. Seaton. Tropical Medicine: Dr. Sandwith. Instruction in Vaccination by Dr. Cope. Dean of the School: Mr. C. S. Wallace. Secretary: Mr. G. Q. Roberts, from whom any further information may be obtained.

UNIVERSITY COLLEGE AND HOSPITAL.—The Faculty of Medicine at University College is divided, as it is at King's College, into a Faculty of Medical Sciences and a Medical School proper.

Faculty of Medical Sciences.—Composition fees.—For the courses required by the University of London. 1. For the Preliminary Scientific Course, 26 guineas, entitling to one attendance and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for one session. 2. For the Intermediate Course, 57 guineas if paid in one sum; 62 guineas if paid in two instalments of 31 guineas each. This fee entitles to attendance on Anatomy and Physiology during three years and to one attendance on Organic Chemistry, Pharmacology, and Materia Medica, and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for two sessions.

For the medical education required by the Examining Board in England and the Society of Apothecaries. First examination, Parts I., II., III., 21 guineas, entitling to one attendance and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for one session. First examination, Part IV. and second examination, 57 guineas if paid in one sum, and 62 guineas if paid in two instalments of 31 guineas each. This fee entitles to attendance during three years and to the privileges of the Union Society (including the use of the gymnasium and the athletic ground at Perivale) for two sessions.

Professors and Lecturers.—1. Preliminary Scientific Course. —Chemistry:—Professor: Sir William Ramsay, K.C.B., F.R.S.; assistant professor: E. C. C. Baly, F.I.C.; assistants: R. W. Gray, Ph.D., N. T. M. Wilsmore, M.Sc., Samuel Smiles, D.Sc.; demonstrators: S. E. Brading, T. P. Hilditch, W. G. Ramsay, N. Whitehouse. Physics:—Professor: F. T. Trouton, M.A., Sc.D., F.R.S.; assistant professor: A. W. Porter, B.Sc.; assistants: N. Eumorfopoulos, B.Sc., A. O. Rankine, B.Sc. Botany:—*Professor*: F. W. Oliver, M.A., D.Sc., F.R.S.; assistant professor: F. E. Fritsch, D.Sc., Ph.D. Zoology:—*Professor*: J. P. Hill, D.Sc.; assistant professor: G. C. Chubb, D.Sc. 2. Intermediate Course.—Anatomy:—Professor: G. D. Thane, LL.D.; assistant and curator of the museum: G. S. Hett, M.B.; demonstrators: G. E. Waugh, B.S., F.R.C.S., H. T. Mant, M.B., B.S.; assistant demonstrators: C. S. White, M.D., M.R.C.P., R. G. Elwell, M.B., B.C. Physiology:—Professor: E. H. Starling, M.D., B.S., F.R.C.P., F.R.S.; assistant professors: W. M. Bayliss, M.A., D.Sc., F.R.S., G. A. Buckmaster, M.A., M.D., D.P.H.; assistant: R. H. Aders-Plimmer, D.Sc.: lecturers: J. H. Parsons, M.B., D.Sc., F.R.C.S., W. Page May, M.D., D.Sc., F.R.C.P., S. B. Schryver, D.Sc. Pharmacology:—Professor: A. R. Cushny, M.A., M.D., F.R.S. *Organic Chemistry:—Professor*: J. N. Collie, Ph.D., LL.D., F.R.S.; assistant: Samuel Smiles, D.Sc.

also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 12 cases of labour, or three months of the Practice of a Lying-in Hospital, six cases being personally conducted. The University also requires further study in Post-Mortem Examinations, Fevers, and Ophthalmology, and recommends study in other special subjects. If a candidate has completed in a University of the United Kingdom a course of study and passed an examination in Botany, Zoology, Physics, or Chemistry, qualifying for a degree in Science or in Arts, he is held to have passed the examinations in such subject or subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence, and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The Fees for M.B. and Ch.B. are £23 2*s.* The class fee in each subject of the curriculum for M.B. and Ch.B. is £2 2*s.*, £3 3*s.*, or £4 4*s.*, and the present fees for hospital attendance are £10 10*s.* The fee for M.D. is £10 10*s.* (stamp duty being now abolished), and for Ch.M. £10 10*s.*

During last academic year there were 653 men and 58 women attending University courses in the Faculty of Medicine—a total of 711. The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Ruchil and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary.

Bursaries and Prizes to the annual amount of over £1000 are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1600 may be held by medical students who have gone through the Arts course.

Professors—Natural Philosophy: A. Gray, LL.D., F.R.S. Materia Medica: Ralph Stockman, M.D. Chemistry: John Ferguson, LL.D. Surgery: Sir William Macewen, M.D., F.R.S. Practice of Medicine: Sir Thomas McCall Anderson, M.D. Midwifery: Murdoch Cameron, M.D. Anatomy: John Cleland, M.D., F.R.S. Zoology: John G. Kerr, M.A. Botany: F. O. Bower, D.Sc., F.R.S. Physiology: D. Noel Paton, M.D. Forensic Medicine: John Glaister, M.D. Clinical Surgery: Sir H. C. Cameron, M.D. Clinical Medicine: S. Gemmell, M.D. Pathology: Robert Muir, M.A., M.D.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.). The two degrees of M.B. and Ch.B. are not conferred separately and the higher degrees of M.D. and Ch.M. are only granted to holders of the M.B. and Ch.B. degrees.

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must pass a Preliminary Examination in (1) English, (2) Latin, (3) Mathematics, and (4) Greek, or French, or German. In the case of a candidate whose native language is not English an examination in the candidate's native language may be substituted for one in French or German, and an examination in any other classical language for one in Latin or Greek. The curriculum for the degrees extend over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence and Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons, and they must have attended courses of at least nine months in clinical medicine and clinical surgery. The candidate must have acted as clerk in the medical and dresser in the surgical wards of a hospital and must have attended for at least six months the practice of a dispensary or the out-practice of a hospital, &c. Attendance is also required on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem Examinations, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 12 Midwifery cases.

Professional Examinations are held twice in each year—namely, in March and July, directly after the close of the winter and summer sessions.

The fee for the degrees of M.B. and Ch.B. amounts to £23 2*s.* Matriculation fee for the winter and summer sessions, £1 1*s.*; summer session alone, 10*s.* 6*d.*

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions (daily), Royal Lunatic Asylum, Ophthalmic Institution, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented for approval by the Medical Faculty and an examination has to be passed in Clinical Medicine or Clinical Surgery as the case may be. Fee for each of the degrees £10 10*s.*

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination. The diploma can be entered on the Register of the General Medical Council.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Professors—Natural Philosophy: C. Niven, M.A., F.R.S. Physiology: J. A. MacWilliam, M.D. Medicine: David White-Finlay, M.D. Chemistry: F. R. Japp, LL.D., F.R.S. Anatomy: R. W. Reid, M.D., F.R.C.S. Surgery: A. Ogston, C.M. Materia Medica: J. T. Cash, M.D., F.R.S. Midwifery: W. Stevenson, M.D. Forensic Medicine: Matthew Hay, M.D. Botany: J. W. H. Trail, M.D., F.R.S. Pathology: D. J. Hamilton, M.B. Natural History: J. Arthur Thomson, M.A.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE, ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

The following are extracts from the Regulations for Degrees in Medicine contained in Ordinance No. 45 (St. Andrews, No. 4) of the Commissioners under the Universities (Scotland) Act, 1889. These regulations came into force on April 19th, 1897. Four degrees in Medicine and Surgery shall be conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a Preliminary Examination in (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects:—(α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other Modern Language, (ζ) Logic. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial or foreign universities shall exempt from the

G. F. Blacker. Diseases of Childhood: Dr. H. Batty Shaw, Mr. Raymond Johnson, Mr. Percy Flemming, and Mr. Herbert Tilley. Pathology and Morbid Anatomy—General Pathology: Dr. Sidney Martin. Practical Pathology: Dr. D. N. Nabarro, Assistant Professor; and Dr. A. C. Stevenson, Assistant Bacteriologist. Laboratory and Special Instruction: Dr. Sidney Martin. Chemical Pathology and Clinical Pathology and Post-mortem Examination: Dr. F. H. Thiele. Museum of Pathological Anatomy: Mr. T. W. P. Lawrence, Curator. Forensic Medicine: Dr. J. S Risien Russell. Diseases of the Eye—Ophthalmic Medicine and Surgery: Mr. Percy Flemming. Clinical Ophthalmology: Mr. Percy Flemming and Mr. J. Herbert Parsons. Diseases of the Ear and Throat: Mr. Herbert Tilley. Diseases of the Skin: Dr. H. Radcliffe Crocker. Mental Physiology and Mental Diseases: Dr. W. Julius Mickle. Dental Surgery: Mr. Sidney Spokes and Mr. H. J. Relph. Instruction in the Use of Anæsthetics: Dr. Dudley W. Buxton. Electro-therapeutic Department: Mr. E. S. Worrall. Radiographic Department: Mr. R. Higham Cooper. Practical Pharmacy: Mr. R. R. Bennett.

WESTMINSTER HOSPITAL.—The hospital contains 215 beds and affords relief to upwards of 2000 in-patients and 80,000 out-patients annually. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædics, and for Diseases of Women, and a special ward for children. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

A medical and a surgical registrar, each with a salary of £50, are appointed annually. Two house physicians, three house surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons; also one assistant house physician and one assistant house surgeon with commons only. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster school for the teaching of these subjects at King's College. Students, however, join the Westminster Medical School as formerly and the Entrance Scholarships remain as heretofore.

There is laboratory accommodation for practical work in Chemistry, Physics, Biology, Anatomy, Physiology, Histology, Pathology, and Bacteriology, and a new Clinical Laboratory has recently been erected. Facilities for research are afforded in all the laboratories.

For out-door recreation the following clubs exist: the Athletic Sports Club, the Cricket, Lawn Tennis, and Swimming Clubs, and the Rugby and Association Football Clubs. For in-door recreation there are the Students' Club and the Guthrie Society, the latter being a debating club. These clubs and societies together constitute the Clubs Union, for membership of which students are not required to pay, the expense being covered by the entrance fee to the school.

Staff.—Consulting Medical Staff: Dr. H. B. Donkin and Dr. W. H. Allchin. Consulting Surgical Staff: Mr. Richard Davy, Mr. G. Cowell, and Mr. N. C. Macnamara. Consulting Dental Surgeon: Dr. J. Walker. Medical In-patient Staff: Dr. de Havilland Hall, Dr. W. Murrell, and Dr. R. G. Hebb. Obstetric Physician: Dr. W. Rivers Pollock. Surgical In-patient Staff: Mr. C. Stonham, Mr. W. G. Spencer, and Mr. A. H. Tubby. Medical Out-patient Staff: Dr. A. M. Gossage, Dr. Purves Stewart, Dr. Bertram Abrahams, and Dr. Eric Macnamara. Physician for Diseases of the Skin: Dr. T. Colcott Fox. Assistant Obstetric Physician: Dr. G. H. Drummond Robinson. Surgical Out-patient Staff: Mr. W. Turner, Mr. E. P. Paton, Mr. Arthur Evans, and Mr. Rock Carling. Surgeon in Charge of the Throat Department: Mr. P. R. W. De Santi. Ophthalmic Surgeon: Mr. G. Hartridge. Surgeon in charge of the Orthopædic Department: Mr. A. H. Tubby. Surgeon in charge of the Ear Department: Mr. P. R. W. De Santi. Dental Surgeons: Mr. C. W. Glassington and Mr. E. Gardner. Administrators of Anæsthetics: Dr. N. W. Bourns and Dr. V. B. Orr. Assistant Anæsthetist: Dr. Cecil Hughes. Physician Pathologist: Dr. R. G. Hebb. Assistant Pathologist and Curator of Museum: Dr. J. M. Bernstein. Medical Registrar: Dr. Price. Surgical Registrar: Mr. J. M. G. Swainson. Pharmacist: Mr. A. E. Tanner. Secretary: Mr. S. M. Quennell.

Lecturers.—Clinical Medicine: Dr. Hall, Dr. Murrell, and Dr. Hebb. Clinical Surgery: Mr. Stonham, Mr. Spencer, and Mr. Tubby. Clinical Gynæcology: Dr. Pollock (treasurer of the school). Medicine: Dr. Allchin, Dr. Murrell, Dr. Hebb, Dr. Gossage, Dr. Purves Stewart, Dr. Abrahams, Dr. Macnamara, and Dr. Duncan. Diseases of the Skin: Dr. Colcott Fox. Insanity: Dr. Robert Jones. Surgery: Mr. Spencer. Ophthalmic Surgery: Mr. Hartridge. Surgery of the Throat and Nose: Mr. De Santi. Orthopædic Surgery: Mr. Tubby. Aural Surgery: Mr. De Santi. Dental Surgery: Mr. Glassington. Anæsthetics: Dr. Bourns. Operative Surgery: Mr. Stonham. Surgical Anatomy: Mr. Arthur Evans. Practical Surgery: Mr. Turner and Mr. Rock Carling. Surgical Pathology: Mr. Paton (Dean of the school). Midwifery and Diseases of Women: Dr. Pollock. General Pathology and Morbid Anatomy: Dr. Hebb. Post-mortem Demonstrations: Dr. Hebb. Materia Medica, Therapeutics, and Pharmacology: Dr Dixon. Demonstrator of Practical Pharmacy: Mr. A. E. Tanner. Forensic Medicine: Mr. Henslowe Wellington. Toxicology: Dr. H. Wilson Hake. Public Health: Dr. S. Monckton Copeman. Bacteriology: Dr. Bernstein. Anatomy: Dr. Thompson and Mr. Jenkins. Demonstrator of Practical Anatomy: Mr. Jenkins. Physiology: Dr. Halliburton. Practical Physiology and Histology: Dr. Halliburton, Dr. Lyle, Dr. Myers, and Dr. Rosenheim. Biology: Dr. Bottomley and Mr. Schwartz. Chemistry and Practical Chemistry: Dr. Thomson, Mr. Jackson, and Mr. Kirkaldy. Physics: Dr. Harold A. Wilson, Mr. Allen, Mr. Nicol, and Dr. W. Wilson. Secretary and Librarian: Mr. W. Fryer.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the University of London, after the completion of the Preliminary Scientific year, is £135 in one sum, or £145 in four instalments. The fee for the Preliminary Science classes is £25. The fee for the course for the University of Durham, the Society of Apothecaries, and the Conjoint Colleges of Scotland, including Elementary Science, is £140 in one sum, or £150 in four instalments.

The hospital contains 165 beds, of which 78 are reserved for surgical, 64 for medical, 13 for gynæcological, six for ophthalmic, and four for isolation cases. The number of in-patients treated during the past year was 2474. There is also a department for attending women in their confinements at their own homes Students can also attend the in-patient and out-patient practice of the New Hospital for Women.

Special classes for the Preliminary Scientific examination of the University of London are held and special courses of instruction in Anatomy, Physiology, and Practical Pharmacology are provided for students preparing for the Intermediate M.B. Examination of the University of London.

In addition to the list of Scholarships tabulated in another column three Evans Prizes of £3 3s., £2 2s., and £1 1s. are given in alternate years on the results of the class examination in midwifery, and two Durham Prizes, value £5 and £3, are given in alternate years on the results of the class examination in gynæcology, and a prize of £5 is awarded in alternate years on the results of the class examination in Midwifery and Gynæcology respectively The Evans Prize for Operative Midwifery, value £5 5s., is awarded yearly. Prizes of £10 each are awarded yearly in Anatomy and Physiology. There is also a small fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help Honoraria from the Mary Royce Memorial Fund are given to the assistant anæsthetists at the Royal Free Hospital. Prizes and Certificates of Honour are awarded in each class at the end of the session.

Students after qualification can hold at the Royal Free Hospital the posts of house physician, house surgeon, clinical assistants, anæsthetist and assistant anæsthetists, medical and surgical registrars, medical electrician, and museum curator; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Chemistry, and museum curator. They can also hold posts at the New Hospital for Women, which is officered entirely by medical women.

The School buildings have been entirely rebuilt in recent years and there are spacious, well-equipped laboratories, *Master in Surgery.*—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than *two years from the date of his registration in the study*, or study and practice, of his profession. He must then pass *an examination in the following subjects*:—1. Clinical Surgery. 2. Operative Surgery. 3. Surgical Pathology. 4. Surgery. 5. Surgical Anatomy (on the dead subject), and one of the following optional subjects:—1. Surgery in one of the following branches—viz., Ophthalmic and Aural, Gynæcological and Dental. 2. Mental Disease. 3. Medical Jurisprudence and Hygiene. 4. Advanced Anatomy and Physiology. 5. Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must be fully qualified and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery. He is then required to pass an examination in the following subjects:—1. Practice of Midwifery. 2. Gynæcology. 3. Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. Fee for the degree of Master in Obstetric Science, £5.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine and must have completed two years in Arts and five years in Medical Studies. The Course and Examination necessary for the diplomas are the same as for the degrees. A diploma in Medicine, Surgery, and Midwifery is a registrable qualification conferred upon candidates who have completed a full five years' course in Medicine and two years in Arts. The diploma, like the degree, qualifies for registration. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by paying the degree fees. Fee for the *Liceat ad Examinandum*, £10. Fee for the diplomas in Medicine, Surgery, and Midwifery, £11.

Professors—Natural Philosophy: F. Purser, M.A. Anatomy and Surgery: A. F. Dixon, D.Sc., M.B. University Anatomist: Sir C. B. Ball, M.D., M.Ch. Physic (Regius): James Little, M.D. Surgery (Regius): Sir C. B. Ball, M.Ch. Surgery: E. H. Taylor, M.D. Botany: H. H. Dixon, Sc.D. Chemistry: Sidney Young, Sc.D. Comparative Anatomy and Zoology: H. W. Mackintosh, M.A.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, Prizes, Scholarships, and Studentships in this University are open to students of either sex.

Candidates for any degree in this University must have passed either the Matriculation Examination or the Senior Grade Examination of the Board of Intermediate Education for Ireland in the subjects prescribed for the Matriculation Examination of this University. Candidates can only claim exemption from the Matriculation Examination of this University by applying for such exemption in the same year in which they shall have passed aforesaid examination. Students from other universities and colleges are included in this rule.

The following degrees, &c., are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics and Master of Obstetrics; in Sanitary Science, a special diploma; and in Mental Disease, a special diploma.

The course for degrees in Medicine, &c., is of at least five years' duration.

The First Examination in Medicine.—Students may be admitted to this examination after the lapse of one academical year from the time of their matriculation. They must also have previously passed the First University Examination and completed the first year of the medical curriculum. The subjects of this examination are Natural Philosophy, Systematic Chemistry, Zoology and Botany. The examination in each subject will comprise two parts:—(1) a written examination and (2) a practical examination. Particular weight will be given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination did not obtain 30 *per cent.* of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of those languages will involve the loss of the examination.

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one medical year from the time of passing the First Examination in Medicine, provided they have completed the second year of the medical curriculum. The subjects for this examination are Anatomy, Physiology, and Practical Chemistry.

The Third Examination in Medicine.—Students will be admitted to this examination after the lapse of one medical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of the medical curriculum. The subjects for this examination will be Anatomy, Physiology, and Materia Medica (Pharmacology and Therapeutics).

The Examination for the Medical Degrees.—Students will be admitted to this examination after the lapse of not less than one medical year from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the entire medical curriculum. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology, Mental Diseases, Medical Jurisprudence and Sanitary Science. (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology; Surgical Pathology. (*c*) Midwifery and Diseases of Women and Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M.B., B.Ch., and B.A.O., receive a certificate of having passed a qualifying examination in the subjects of Medicine, Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to these Degrees.

The M.D. Degree.—Candidates may present themselves for the examination for this degree after the lapse of three academical years from the time of obtaining the degrees of M.B., B.Ch., B.A.O. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising thereon.

The M.Ch. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; Surgical Pathology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination on Surgical Instruments and Appliances; and (*d*) an examination in Operative Surgery.

The M.A.O. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children, Pathology, and the Use of Instruments and Appliances and will include—(*a*) a written examination; (*b*) a clinical examination so far as practicable; and (*c*) an oral examination, with practical illustrations.

UNIVERSITY OF WALES.

This University has not as yet the privilege of granting degrees in Medicine. At the three constituent Colleges of Aberystwyth, Bangor, and Cardiff there are Professors of Chemistry, Botany, Zoology, and Physics, so that the students of the University can obtain proper instruction in the ancillary subjects. The foundation of a Medical Faculty has been laid at University College, Cardiff, where there is a recognised school of medicine terms of office. Further particulars from Dr. T. J. Horder, 141, Harley-street, W. Consulting Physicians: Sir S. Wilks, Bart., and Dr. R. Burnet. Physicians: Dr. E. C. Beale, Dr. C. E. Beevor, Dr. A. Morison, Dr. T. J. Horder, Dr. Symes Thompson, and Dr. Willcox. Obstetric Physicians: Dr. G. F. Blacker and Dr. Cuthbert Lockyer. Physician for Skin: Dr. A. Whitfield. Surgeons: Mr. P. T. B. Beale, Mr. G. B. M. White, Mr. E. C. Stabb, Mr. V. W. Low, and Mr. Arthur Edmunds. Ophthalmic Surgeons: Mr. A. S. Morton and Mr. Gay French. Throat and Ear Surgeon: Mr. E. B. Waggett. Dental Surgeon: Mr. C. Peyton Baly.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—This general hospital is in the midst of a densely-populated neighbourhood of about half a million inhabitants. It contains medical, surgical, gynæcological, and children's wards, having in all 125 beds. There are special departments for gynæcological cases, diseases of the eye, ear, throat, and nose, skin diseases, medical electricity and radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction is given daily in the wards and out-patient departments in connexion with the North-East London Post-graduate College attached. There are four Resident Medical Officers, and Clinical Assistants are appointed under certain conditions. Further particulars in regard to the hospital may be obtained from Mr. H. W. Carson, Secretary to the Medical Committee, 26, Welbeck-street, W.; or from Dr. A. J. Whiting, Dean of the North-East London Post-Graduate College, 142, Harley-street, W. Consulting Physicians: Sir James Reid, Bart., and Dr. Percy Kidd. Consulting Surgeons: Mr. J. Langton, Mr. G. Lichtenberg, and Mr. Hooper May. Physicians: Dr. R. Murray Leslie, Dr. G. P. Chappel, and Dr. A. J. Whiting. Assistant Physicians: Dr. A. G. Auld and Dr. T. R. Whipham. Surgeons: Mr. Walter Edmunds and Mr. H. W. Carson. Assistant Surgeon: Mr. J. Howell Evans. Gynæcologist: Dr. A. E. Giles. Surgeon to Ear, Nose, and Throat Department: Mr. H. W. Carson. Ophthalmic Surgeon: Mr. R. P. Brooks. Physician for Skin Diseases: Dr. G. Norman Meachen. Medical Officer in charge of the X Ray and Electrical Departments: Dr. A. H. Pirie. Dental Surgeon: Mr. W. Donston. Anæsthetics: Mr. A. De Pronderville, Mr. F. Herbert Wallace, and Dr. W. S. Frith. Pathologist: Dr. G. Macdonald. Medical Registrar: Dr. G. Basil Price. Surgical Registrar: Mr. E. Gillespie. Secretary: Mr. F. W. Drewett.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873).—Physicians: Dr. Fenwick, Dr. Parkinson, and Dr. Addinsell. Surgeon: Sir William J. Collins. Assistant Surgeon: Mr. H. J. Paterson. Dental Surgeon: Mr. A. Alexander. The hospital contains 110 beds. The in-patients in 1905 were 1266, and the out-patients and casualties numbered 25,216 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Special departments for Ophthalmology and Gynæcology. Operations: Mondays and Thursdays, 3.30 P.M. Classes will be held during the winter and summer sessions for students preparing for the final examinations at the Colleges and the Universities.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Negotiations are pending between this hospital and the Hampstead General Hospital, with the approval of the King's Hospital Fund for London, for the amalgamation of the two institutions. If this takes place the North-West London Hospital will become an out-patient annexe of the Hampstead General Hospital and the latter institution will accommodate the in-patients from the districts which the North-West London Hospital now serves. We append below the present staff of the North-West London Hospital, some of whom are certain to hold office under the combined scheme. Consulting Physician: Dr. Donald W. C. Hood. Consulting Surgeon: Mr. Frederic Durham. Physicians: Dr. Harry Campbell, Dr. W. Knowsley Sibley, Dr. G. A. Sutherland, and Dr. C. O. Hawthorne. Surgeons: Mr. M. P. Mayo Collier, Mr. J. Jackson Clarke, and Mr. George Templeton. Assistant Surgeon: Mr. J. W. Thomson Walker. Physician for Diseases of the Skin: Dr. J. Herbert Stowers. Obstetric Physician: Dr. F. E. Taylor. Ophthalmic Surgeon: Sir William J. Collins. Dental Surgeon: Mr F. Talbot. Anæsthetists: Dr. G. A. H. Barton and W. E. Hills. Resident Medical Officers: Mr. J. R Kemp and Mr. A. O'Neill. The hospital, which was established in 1878, provides 50 beds. The average number occupied last year was 45. It is a general hospital. There are two spacious wards for men and women respectively. The children's ward contains 15 cots. There are two Resident Medical Officers—an honorarium at the rate of £50 per annum attaches to each post. Operation days, Monday and Thursday at 2.30 o'clock. Further particulars from the secretary at the hospital.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Physicians for In-patients: Miss Cock, M.D., and Miss Walker, M.D. Surgeons for In-patients: Mrs. Boyd, M.D., and Miss Aldrich-Blake, M.D., M.S. Physicians and Surgeons for Out-patients: Miss Macdonald, M.B., Miss Chadburn, M.D., B.S., Miss Anderson, M.D., B.S., and Miss Woodcock, M.D., B.S. Children's Department: Mrs. Flemming, M.D. Ophthalmic Surgeon: Miss Sheppard, M.B. Assistant Physicians for Out-patients: Miss Stoney, M.D., Miss Platt, M.B., Miss Campbell, M.D., B.S., Miss Miss Hamilton, M.D., B.S., Miss Bone, M.D. Senior Obstetric Assistant: Miss Turnbull, M.D. Anæsthetists: Miss Browne, L.S.A., Miss Turnbull, M.D., and Miss Payne, M.B. A considerable number of the students hold posts in the New Hospital under the visiting staff, and in return for much valued clinical teaching they do the work assigned to students in the wards of a general hospital. Secretary: Miss M. M. Bagster.

FRENCH HOSPITAL AND DISPENSARY, Shaftesbury-avenue, W.C.—This hospital which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language has 70 beds. It has a convalescent home at Brighton with accommodation for 33 patients and a pavilion for the preventive treatment of consumption. Physicians: Dr. G. Ogilvie and Dr. L. Williams. Physicians to the Out-patients: Dr. L. Vintras, Dr. H. Dardenne, and Dr. J. P. Baronoff Surgeons: Mr. E. Owen, Mr. H. de Méric and Mr. W. H. Clayton-Greene. Obstetric Physician: Dr. S. Sunderland. Ophthalmic Surgeons: Mr. C. Higgens and Mr. G. W. Thompson. Dental Surgeon: Mr. M. Thomson. Honorary Anæsthetist: Mr. H. Davis. Resident Medical Officers: Mr. A. D. Kennard and Mr. K. Eckenstein.

GERMAN HOSPITAL, Dalston, N.E.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for cases of emergency and of accident. It has 130 beds, including a sanatorium with six beds and a convalescent home with 17 beds. Consulting Physician: Sir H. Weber. Consulting Surgeon: Mr. R. W. Parker. Physicians: Dr. F. P. Weber, Dr. K. Fürth, and Dr. D. O'C. Finigan. Surgeons: Mr. E. Michels, Mr. J. P. zum Busch, and Mr. G. J. Jenkins. Ophthalmic Surgeons: Mr. R. Gruber and C. Markus. Anæsthetist: Mr. H. V. Price. Resident Medical Officers: Mr. W. Stockert, Mr. W. Engels, Mr. S. Chapuis, and Mr. K. Rupp.

ITALIAN HOSPITAL.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 60 beds. Honorary Consulting Physicians: Cav. Dr. M. Castaneda and Sir Dyce Duckworth. Honorary Consulting Surgeon: Sir Frederick Treves. Physicians: Cav. Dr. F. Naumann, Cav. Dr. F. Melandri, and Dr Vincent Dickinson. Assistant Physician: Dr. Herbert Danvers. Surgeon: Mr. George Lenthal Cheatle, C.B. Assistant Surgeon: Mr. T. P. Legg. Throat and Ear Department: Cav. Mr. J. Donelan. Ophthalmic Surgeon: Mr. Stanford Morton. Consulting Dental Surgeon: Cav. Mr. J. FitzGerald. Assistant Dental Surgeon: Mr. E. Whishaw Wallis. Anæsthetists: Dr. Hugh Richard Phillips and Mr. Laurence Galsworthy.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—The hospital, with the Finchley branch, contains 200 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday at 2.30 P.M. In- and out-patient practice and electrical-room treatment at that hour. Physicians: Dr. Hughlings Jackson, Dr. Buzzard, Dr. Bastian, Sir William Gowers, Dr. D. Ferrier, Dr. Ormerod, and Dr. Beevor. Physicians for Out-patients: Dr. Tooth, Dr. James Taylor, Dr. J. S. Risien Russell, and Dr. Aldren Turner. Assistant Physicians: Dr. Batten, Dr. J. S. Collier, and Dr. F. Buzzard. Surgeons: Sir Victor Horsley, Mr. C. A. Ballance, Mr. Donald J. Armour, and Mr. Percy W. G.

of having attended Lectures on Midwifery; Practical Instruction in Midwifery; Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women; and of attendance on 20 Labours.

The fees for admission to the *Third* or *Final Examination* are as follows: For the whole examination, £21. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s.*; for re-examination in Practical Pharmacy (if taken at this examination), £2 2*s.* Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5*s.* Part III. For re-examination in Midwifery and Diseases Peculiar to Women, £3 3*s.*

A candidate referred on the *Third* or *Final Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology, on production of the required certificates.

Graduates in Medicine of certain recognised Indian, Colonial, and Foreign universities may present themselves for the Final examination under special conditions which can be ascertained on application to the Secretary.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

In addition to the diplomas granted by the English Conjoint Board, the Royal College of Physicians of London and the Royal College of Surgeons of England grant honour diplomas, which no longer give the right to practise professionally if held separately. The Royal College of Physicians of London has two such diplomas, the *Fellowship* which is a purely honorary distinction and the *Membership* which is obtained by examination.

Membership.—Every candidate for the Membership of the College must furnish proof of having attained the age of 25 years. Candidates must not be engaged in trade, dispense medicine, make any engagement with a chemist, or any other person for the supply of medicine, or practise medicine or surgery in partnership, by deed or otherwise. Any candidate being already registered or having passed a qualifying examination in accordance with the Medical Act of 1886, who has obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or who has obtained a foreign qualification entitling him to practise medicine or surgery in the country where such qualification has been conferred, wherein the courses of study and the examinations to be undergone previously to graduation have been adjudged by the Censors' Board to be satisfactory, will (if the Censors think fit) be admitted to the Pass Examination. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The examination is directed partly to pathology and partly to the practice of medicine and may be modified in circumstances to be ascertained by application to the Registrar. For example, candidates under 40 years of age are examined in an ancient or modern language, a test from which their seniors are exempt. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee already paid for the Licence shall be deducted from the 40 guineas. The fee for the examination is £6 6*s.*

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members.*

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. A certain number of Members of long standing are also elected to the Fellowship. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology and the questions on these subjects may require an elementary acquaintance with Comparative Anatomy and Physiology. The examination is partly written and partly *vivâ voce.* The subjects of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examination is partly written and partly *vivâ voce* and includes the examination of patients and the performance of operations on the dead body. The examinations are held during the months of May and November of each year.

The fees for examination are:—First Examination, each admission, five guineas. Second Examination, each admission, 12 guineas. Of such examination fees 17 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Membership. A candidate who is not a member of the College is admissible to the first Professional Examination for the Fellowship on the production of evidence of having passed the First and Second Examinations of the Examining Board in England by the Royal College of Physicians of London and the Royal College of Surgeons of England (or, if a member of a University recognised by the College for the purpose, of having passed the Examinations in his University equivalent to the First and Second Examinations of the Board) and on the production of certificates of attendance upon certain courses of study described in the Regulations.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Secretary of the Examining Board, Examination Hall, Victoria Embankment, London, W.C.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries. The regulations which follow are for candidates who commenced study after Jan. 1st, 1892.

Professional Education.—1. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of

Surgeon: Mr. L. H. McGavin. Surgeon Dentist: Mr. C. G. May. Anæsthetists: Mr. C. J. Ogle and Dr. M. Horne. *Pathologist:* Dr. S. J. Aarons. Registrar, Dr. W. A. Milligan. House Physician: Dr. E. B. Holland.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—The hospital *maintains* 119 *cots*, and on an average 259 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which *is* recognised by the Conjoint Board for England as a school of medical teaching for students *in the fifth* year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or *unqualified students are open* every three months, subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed *in the out-patient* department. Any additional information may be obtained on applying to Mr. Cuthbert S. Wallace or to W. M. Wilcox, the Secretary, at the hospital. Physicians: Dr. Eustace Smith, Dr. J. A. Coutts, Dr. Morley Fletcher, Dr. E. Graham Little, and Dr. A. M. Gossage. Surgeons: Mr. Cuthbert S. Wallace and Mr. W. Trotter. Assistant Physicians: Dr. Clive Riviere, Dr. *W. P. S. Branson, and Dr. T. Fisher.* *Assistant* Surgeons: Mr. W. H. Bowen and Mr. R. Warren. Ophthalmic Surgeon: Mr. W. I. Hancock. Dental Surgeon: Mr. E. S. Pierrepont. Medical Officer for the Electrical Department: Dr. G. Graham. Medical Officer for the Casualty Department: Dr. J. R. Cook. Resident Medical Officer: Dr. W. N. May. House Physician: Mr. N. Allin. House Surgeon: W. Berry. Secretary: W. M. Wilcox.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C., contains 222 beds, divided into 95 medical, 105 *surgical, and 22 for special and* infectious cases, besides 38 beds at the convalescent branch, Highgate. The hospital having been recognised by the Conjoint Board for England *as a place* where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students who have completed four years of medical study and also to qualified medical men. The medical staff are recognised by the University of London as teachers in Diseases of Children. Appointments are made every three months to *six medical clerkships, which are open to students of the* hospital. Lectures or demonstrations are given once every week during both winter and summer sessions, which *qualified practitioners are invited to attend free of* charge. There is a museum in connexion with the hospital. The sessions are of ten weeks' duration, and begin in October, January, and March. *Fees for hospital practice,* three months, 3 guineas; perpetual ticket, 5 guineas. Consulting Physicians: Dr. W. H. Dickinson, Dr. W. B. Cheadle, Sir Thomas Barlow, *Bart.,* Dr. D. B. Lees, and Dr. F. G. Penrose. Physicians: Dr. A. E. Garrod, Dr. A. F. Voelcker, Dr. W. S. Colman, and Dr. F. E. Batten. Physicians to Out-patients: Dr. G. F. Still, Dr. F. J. Poynton, Dr. Robert *Hutchison, Dr.* H. Thursfield, and Dr. T. Thompson. Consulting Surgeons: Sir Thomas Smith, Bart., Mr. Howard Marsh, Mr. Edmund Owen, Mr. John Morgan, and Mr. Bernard *Pitts. Surgeons:* Mr. W. Arbuthnot Lane, Mr. Thomas H. Kellock, Mr. H. Stansfield Collier, and Mr. Francis J. Steward. Surgeons to Out-patients: Mr. Edred M. Corner, Mr. G. E. *Waugh, and* Mr. H. A. T. Fairbank. Ophthalmic Surgeon: Mr. J. Herbert Parsons. Aural Surgeon: Mr. G. E. Waugh. Dental Surgeon: Mr. W. Warwick James. Honorary *Anæsthetist:* Dr. R. W. Collum Radiographer: Dr. Ironside Bruce. Local Medical Officer for Cromwell House: Dr. A. M. Henderson. Medical Registrar: Dr. Langmead. *Clinical* Pathologist and Bacteriologist: Mr. Graham Forbes. Anæsthetists: Mr. Graham Scott, Mr. E. E. Argles, and Mr. R. Delbruck. Resident Medical Superintendent: Mr. H. T. Gray. Secretary: Mr. Stewart Johnston.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—This hospital *contains* 76 cots and a very extensive Out-patient Department. About eight or ten clinical assistants to work with the Honorary Medical Staff for Out-patients are appointed *quarterly for a period of three* months, but there is no salary attached to this post. Consulting Physicians: Dr. J. F. Goodhart, Dr. Frederick Taylor, and Dr. Nestor Tirard. Physicians: Dr. J. Charlton Briscoe and Dr. T. R. C Whipham. Physicians in charge of Out-patients: Dr. D. Forsyth and Dr. H. O. Mann. Consulting Surgeons: Sir H. G. Howse, Mr. R. Clement Lucas, Mr. G. H. Makins, Mr. F. S. Eve, Mr. F. C. Abbott, and Mr. A. H. Tubby. Surgeons: Mr. C. H. Fagge and Mr. H. S. Clogg. Surgeons in charge of Out-Patients: Mr. W. M. Mollison and Mr. C. A. R. Nitch. Dental Surgeon: *Mr. Denison Pedley.* Ophthalmic Surgeon: Mr. Sydney Stephenson. Aural Surgeon: Mr. S. R. Scott. House Physician: Mr. Langford Davies. House Surgeon: Mr. H. *Wyatt. Assissant House Surgeon:* Mr. S. G. Corner. Pathologist: Mr. A. N. Leathem. Dispenser: Mr. F. A. Hocking. Radiographer: Mr. R. H. Cooper.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W.—The hospital contains 104 beds and has a *large out-patient department* (over 1200 weekly); the home at Broadstairs has 50 beds. Consulting Physicians: Sir Francis Laking and Dr. Ridge Jones. Consulting Surgeons: Mr. Cowell, Mr. Pickering Pick, and Mr. D'Arcy Power. Physicians: Dr. Montague Murray, Dr. Walter Carr, Dr. Humphry D. Rolleston, Dr. Edmund Ivens Spriggs, Dr. A. J. Jex-Blake, and Dr. Charles Miller. Physician to Skin Department: Dr. J. M. H. MacLeod. Surgeons: Mr. H. F. Waterhouse, Mr. Rupert H. Bucknall, and Mr. Joseph Cunning. Surgeons to the Out-patients: Mr. W. Fedde Fedden, Mr. S. Maynard Smith, and Mr. Ralph Thompson. Ophthalmic Surgeon: Mr. C. Devereux Marshall. Dental Surgeon: Mr. C. E. Wallis. Anæsthetists: Dr Randolph Grosvenor, Dr. Reginald H. Tribe, and Dr. C. G. H. Gunning. Resident Medical Officer: Mr. J. D. Marshall. House Surgeon: Mr. Eric Harries. House Physician: Mr. R. S. Jenkins. Secretary: Mr. H. G. Evered. Out-patients are seen as under:—Diseases of the Eye: Wednesday, 2 P.M. Diseases of the Skin: Wednesday, 2 P.M. *Whooping-cough Cases:* Fridays, 9 30 A.M. Medical and Surgical Cases: Monday and Thursday mornings at 9 A.M.; any afternoon except Wednesday and Saturday at 12.30 P.M. *Dental Cases:* Wednesday mornings at 9.30 A.M. Accidents and urgent cases are admitted at any time.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E. (Telephone 305 Dalston). *For the* sick children of the poor under 12 years of age. Established 1867.—125 beds. During the past year 1712 in-patients and 29,864 out-patients (representing 76,247 attendances and including 12,591 casualty cases) were relieved, 625 of the in-patients being under two years of age. Consulting Physicians: Dr. W. Cayley, Dr. W. Pasteur, and Dr. W. A. Wills. Consulting Surgeons: Mr. Jonathan Hutchinson, Mr. Waren Tay, Mr. R. J. Godlee, Mr. Bilton Pollard, and Mr. *H. Percy Dean.* Physicians: Dr. James Taylor, Dr. J. Porter Parkinson, and Dr. George Carpenter. Assistant Physicians: Dr. Charles Bolton and Dr. Sheffield Neave. Surgeons: Mr. Douglas Drew and Mr. Ewen C. Stabb. Assistant Surgeons: Mr. P. Lockhart Mummery and Mr. J. M. G. Swainson. Ophthalmic Surgeon: Mr Sydney Stephenson (Thursday, 2.30 P.M.). Physician *in charge of Skin Department:* Dr. H. G. Adamson. Dental Surgeon: Mr. S. F. Rose (Tuesday, 9.30 A.M., and Friday, 2.30 P.M.). Medical Radiographer: Mr. Percival Dingle. *Pathologist and Bacteriologist:* Dr. W. A. Milligan. Matron: Miss Bushby. Secretary: Mr. T. Glenton-Kerr. The surgeons attend on Wednesdays at 2 P.M. and Fridays and Saturdays at 9.30 A.M.; the physicians daily at 2 P.M., except Saturday, 9.30 A.M. Applications for permission to attend the practice of the hospital should *be addressed to the secretary.*

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields, 1804–1899), City-road, E.C.—138 beds. This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. In 1906 there were 2071 in-patients, the new out-patients were 45,638, and the attendances were 123,355. *Operations are* performed daily from 10 A.M. to 1 P.M. and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3*s.*; perpetual, £5 5*s.* Courses of instruction on the following subjects are given at the hospital periodically: (1) the *use of the* ophthalmoscope; (2) errors of refraction; (3) external diseases of the eye; (4) surgical anatomy of the eye; (5) pathology of the eye; (6) practical *pathology;* (7) motor anomalies; (8) examination of the eye; (9) operative surgery; (10) x ray work; and (11) clinical lectures. A composition fee of £10 10*s.* will entitle *students* of the hospital to a perpetual *ticket* and will admit them *once* to all the above lectures and demonstrations *except* the classes on practical pathology, *operative* surgery, and x ray work. Students of the hospital are *eligible* for the offices of house surgeon or clinical and junior *assistants.*

notice of intention to present himself for examination must be given by the candidate to Mr. James Robertson, solicitor, 54, George-square, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, unless a special application be made to the President of the College. In certain circumstances registered medical practitioners who have distinguished themselves in the practice of their profession are admitted to the Fellowship without examination.

The Royal College of Surgeons of Edinburgh admits to the examination for its Single Licence any candidate who already holds a Diploma in Medicine of any British, Indian, or Colonial university or of any British or Colonial College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are now admitted to the Licence of the College but not to the Fellowship, and the regulations for the *Licence apply to practitioners of either sex.*

Every candidate for a surgical diploma must have followed his course of study in a university, or in an established school of medicine, or in a provincial school specially recognised by the College of Surgeons of that division of the United Kingdom in which it is situate.

Under the title Established School of Medicine are comprehended the medical schools of those cities of Great Britain and Ireland in which Diplomas in Surgery are granted, and such colonial and foreign schools as are similarly circumstanced in the countries in which they exist.

Professional Examination for the Diploma of the College.—Candidates for the Diploma of the College will be subjected to one professional examination, partly in writing and partly practically and orally.

Opportunities for the examinations will be presented four times in each year. On each of these occasions the candidates will assemble to write answers to the questions proposed, and the clinical and oral examinations shall be conducted on the days immediately succeeding.

Unsuccessful candidates will be remitted to their studies for a period to be determined by the judgment of the examiners, but not in any case for less than three months.

The examination will embrace the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and will not take place before the termination of the full period of study.

Applications for examination must be made to Mr. James Robertson, not later than one week prior to the date of examination.

On the production of the required documents Mr. Robertson will give the candidate an order authorising the examiners to admit him to examination.

The fee of £15 15s. payable to the College must be lodged in the hands of Mr. Robertson not later than one week preceding the examination day. The sum of £10 10s. will be returned to each unsuccessful candidate. Under special circumstances candidates can be examined on days other than those fixed by the regulations. The fee for a special examination is as follows, viz., £20 for examination, of which £10 will be returned to candidates remitted on examination.

In order to test more effectually the practical knowledge of candidates recent dissections and anatomical specimens will be employed during examination. They will also be subjected to a practical clinical examination in the Surgical Hospital, including the application of surgical apparatus, bandages, surface markings, &c., and may, if it be considered necessary to test their knowledge, be required to perform operations on the dead body.

THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Faculty of Physicians and Surgeons of Glasgow grant a Fellowship and a Licence to be held as separate qualifications.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery, and 14 days' notice must be given by the candidate of his intention to present himself to Mr. Alexander Duncan, LL.D., the Faculty Hall, Glasgow. The fee for the Fellowship is £20, half of which sum is returned to any successful candidate who already holds the Licence of the faculty. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the faculty is granted as a separate qualification to qualified practitioners after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS, IRELAND.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies, passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.—Candidate must pass four Professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other Licensing body. All examinations shall be conducted so far as possible by demonstration of objects placed before the candidates.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(*a*) lectures on Theoretical Chemistry, winter course; (*b*) Practical Chemistry, three months' summer or winter course; (*c*) Elementary Biology; and (*d*) Physics.

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Biology. The fee for this examination is £15 15s.

Second Professional Examination.—Candidates are not admissible to this examination before the end of their second winter session. Every candidate is required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination, and certificates of having attended—(1) Anatomical Dissections, two courses of six months; (2) Practical Histology, three months; (3) Lectures on (*a*) Anatomy, six months; (*b*) Physiology, six months; (*c*) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10s.

Third Professional Examination.—Candidates are not admitted to this examination before the end of their third winter session. Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination and, in addition to the certificates required for the Second Professional Examination, certificates of having attended—(*a*) Pathology; (1) Systematic, (2) Practical, three months each; (*b*) Materia Medica, Pharmacy, and Therapeutics, three months; (*c*) Forensic Medicine and Public Health, three months; (*d*) Surgery, six months. Satisfactory evidence must be produced of attendance in fever wards in connexion with the hospital attendance in either the third or a subsequent year.

The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9s.

Final Professional Examination.—Candidates may take one or two sections of this examination at the end of the third year but cannot complete it till the expiry of four years from the passing the First Professional Examination. Every candidate is required before admission to produce evidence (1) of having passed the Third Professional Examination; (2) of having attended—(*a*) at a General Hospital for 27

Companies), Calthorpe-street, Gray's Inn-road, W.C.—Officer Commanding: Colonel Valentine Matthews, V.D. The Royal Army Medical Corps (Volunteers) bears the same relation to the Volunteer Army as the Royal Army Medical Corps bears to the regular Army. The course of training has the great advantage of affording, in addition to a knowledge of ordinary military duties, special ambulance instruction useful in all ranks of life. All students who are thinking of entering either of the public services are strongly recommended to join. The instruction received will be found of the greatest advantage to such as intend joining either the Royal Army Medical Corps or the Indian Medical Service on the completion of their hospital course, the work taught in the Royal Army Medical Corps (Volunteers) being practically the same as that taught at the Depôt, Royal Army Medical Corps, Aldershot, and in which an examination is held at the end of the four months' course there before the young officers are drafted to their different stations. A sound knowledge of the work, which can be obtained in the Royal Army Medical Corps (Volunteers) must necessarily be of great benefit to those going through the depôt and give a decided advantage over those who have had no previous military training. In addition to the drills of an ordinary infantry corps, the special training includes stretcher and wagon and cacolet drill; the use of improvised seats and stretchers; the use and application of bandages, splints, &c.; the duties of the *personnel* of a field ambulance; lectures by the officers on first aid to the injured, and on the elements of anatomy, physiology, hygiene, and nursing, which are so arranged as not to interfere with the lectures, &c., carried on at the various hospitals in London. The corps goes into camp for a week in the summer each year for field training. There is also a Shooting Club in the corps, in which instruction in, and facilities for, the practice of rifle shooting are given. There is a Transport Section in connexion with the corps, the members of which go through a course of instruction in riding and driving and transport work with the regular troops. There are also sections of Cyclists and Signallers. A Gymnastic and Boxing Class meets once a week at headquarters, under a professional instructor. Lectures are delivered during the winter session. The Adjutant will give any information respecting the above on application to the headquarters, Calthorpe-street, Gray's Inn-road, W.C.

COOKE'S SCHOOL OF ANATOMY, PHYSIOLOGY, AND OPERATIVE SURGERY, London.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year; these have special advantages both as regards Anatomy and Physiology. Charges are but slightly in excess of current charges and particulars are forwarded on application. By the decision of various examining bodies gentlemen rejected at their Anatomical and Physiological Examinations can get signed up for the supplementary work they are required to put in before re-examination. The operations of surgery are performed on the dead body and the courses are recognised for army promotion. The school possesses a good collection of physiological and chemical apparatus and candidates for the higher examinations receive special instruction in the more difficult subjects.

WHALE OIL *v.* COD-LIVER OIL.—The British consul at Bahia, Dr. D. R. O'Sullivan-Beare, states in a report to the Foreign Office that refined whale oil as prepared at Bahia resembles cod-liver oil so closely in the attributes of colour, consistency, odour, and taste as to be almost indistinguishable therefrom. The oil in question enjoys a high reputation locally for its medicinal properties and is preferred, indeed, to cod-liver oil. There are unfortunately only too many sufferers, consumptives especially, who would benefit from taking cod-liver oil regularly but for whom the high price of that article is prohibitive. In the interests of such persons, the consul adds, it is certainly worth determining whether or not the comparatively cheap whale oil constitutes an efficacious substitute for the more-costly cod-liver oil. The export trade in whale oil is in the hands practically of one firm, which is British. Samples of "ordinary" and "refined" whale oil as prepared at Bahia have been sent to the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, London, where they may be inspected by those interested.

PROVINCIAL MEDICAL SCHOOLS AND HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.[1]

THE number of important provincial medical schools has much grown of late in England mainly owing to the foundation of the new provincial universities. The faculty of medicine of these universities is able to arrange a full medical curriculum for students with access to the different hospitals, large and small, of the university city, and the students at these schools will receive at the end of their medical course a degree in medicine. We have already described the academic procedure to obtain the degrees; we now enumerate the hospitals at which the students of the medical schools of the universities can complete their medical education.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. Pathological demonstrations are given in the post-mortem room at the Pathological Laboratory by the Professor of Pathology. Practical Pharmacy is taught in the Radcliffe Dispensary. Opportunities are offered to students who wish to act as surgical dressers and clinical clerks in the out-patient departments and in the wards. The Infirmary contains 150 beds.

UNIVERSITY OF CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in the special methods of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit. The composition fee for pupilship is 8 guineas.

UNIVERSITY OF DURHAM: THE COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—A new wing has been added to accommodate the departments of physiology and bacteriology. It also contains a students' gymnasium and a set of Students' Union rooms. The new Royal Victoria Infirmary, containing upwards of 400 beds, has been recently opened by His Majesty King Edward VII. In the new infirmary adequate accommodation will be provided for the study of the various special subjects, in addition to the ordinary clinical work. The following Scholarships and Prizes are awarded annually:—Four University of Durham Scholarships, value £25, tenable for four years, for proficiency in Arts, awarded to full students in their first year. The Pears Scholarship, value £50 a year, tenable for three years (when vacant). The Masonic Scholarship, value £15 a year, tenable for three years (when vacant). The Dickinson Scholarship, value interest of £400, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest of £500, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680, for Comparative Pathology. The Stephen Scott Scholarship in Surgery, value the interest of £1000. The late Dr. George Yeoman Heath Scholarship:

---

[1] For Scholarships see p. 634 et seq.

cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Section I. of the Final examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. includes the Principles and Practice of Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section I. of the Final examination cannot be passed before the expiration of 45 months after registration as a medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society. Section II. of the Final examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy. Section II. cannot be passed before the end of the fifth year.

The course of study for the *Primary examination* is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with *Demonstrations*, 12 months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School recognised by the Society. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary.

The course of study for the *Final examination, Section I.*, includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a *medical* school for a period of one winter and one summer session; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership, six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and *Practice* of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship, six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on 20 Midwifery cases. The course of medical study must extend over the above-mentioned period of 45 months and the offices of *dresser or clinical clerk must* be held at a hospital, or other institution recognised by the Society.

The course *of study* for the *Final examination, Section II.*, includes either attendance on the Practice of Medicine and Surgery at a *hospital* or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals *for six months* (*three* months at each hospital), *and for* six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction *in* Infectious Diseases and in Mental Diseases (at a lunatic *asylum or in the* wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, *Laryngology* with Rhinology and Otology, Dermatology, and *Diseases* of Children. No candidate is eligible *for the* Final examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be *obtained of* the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. *of* the Final examination the candidate must produce certificates: (1) of being 21 years of age; (2) of moral *character*; (3) of the course of medical study; (4) of proficiency in vaccination signed by a teacher authorised *by* the Local Government Board; and (5) of instruction in the administration of anæsthetics. Candidates intending to present themselves for examination are required to give 14 days' notice. A form for this purpose will be sent on application.

The fee for the Licence is 20 guineas. The examination offices are open from 10 A.M. to 4 P.M.; on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are four professional examinations, the total fees for which amount to 21 guineas. Ladies are eligible for the diploma. Registered medical practitioners will receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualifications and on paying a fee of 10 guineas. If medicine or surgery be required five guineas extra will be charged.

The fees payable for each examination are as follows:—first professional, £5 5*s.*; second, £5 5*s.*; third, £5 5*s.*; final examination, £6 6*s.* If a candidate *gives* three clear days' notice of his inability to attend he may present himself at the ensuing examination without a further fee. A candidate is allowed for each professional *examination which he* has completed at any other licensing body except the final. If he has passed in some only of the subjects in a given examination he has to pay the whole of the fee for that examination. The *fees* for re-examination are for each subject £1 1*s.*, except in the subjects of chemistry, pharmacy, surgery, medicine, second anatomy, pathology, physiology, and ophthalmology, *the fees for* which are two guineas each. The fee for the third and final or final alone is £15 15*s.* when the other examinations have been taken elsewhere. All examination fees are to be lodged in the Sackville-street Branch of the Royal Bank of Ireland to the credit of the Examination Committee. Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40, Mary-street, Dublin, at least 14 clear days before the first day of examination.

There are four examinations—first, second, third, and final. The first three are held quarterly on the third Monday in January, April, July, and October; the finals are held in January and July. The first examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Pharmacy is put down in this examination, but it *may be* taken at any of the first three examinations. Candidates holding a Pharmaceutical licence are exempt from this subject. The second examination comprises anatomy *of* the whole body (including practical dissections), materia *medica* and therapeutics, physiology and practical histology. The third examination comprises pathology, materia *medica* if not taken at second examination, medical jurisprudence, and hygiene. The final examination *comprises* medicine, including clinical and oral, surgery, including operations, clinical and oral, ophthalmic surgery, including clinical and oral, midwifery, and gynæcology.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries' Hall in Ireland must *before proceeding* to the final examination produce evidence of having been registered as medical students for 57 months, *also of having* attended courses of instruction as follows:—one course each (of six months) of the following: anatomy (lectures), chemistry (theoretical), midwifery, practice of medicine, physiology, surgery, and dissections, two courses of six months each. Courses of three months: materia medica, *medical* jurisprudence, chemistry (practical), practical physiology and histology, operative surgery, physics, clinical ophthalmology, biology, clinical instruction in *mental* disease, pathology, and a course in vaccination. Medico-chirurgical hospital, 27 months *to be* distributed, at the student's own discretion, over the last four years *of* his study. The candidate may substitute for nine months amongst those set for the other Entrance Scholarships. James Gaskill.—£35, tenable for two years. Subjects: Mathematics, Geometry (the substance of Euclid I.—IV. and VI.), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry. Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German. Manchester Grammar School.—£25 per annum, tenable for three years. The examinations for all these scholarships are held in the month of May. Kay-Shuttleworth (Sir James Phillips).—£30 per annum, tenable for three years. Subjects: Mathematics, Elementary Mechanics, Chemistry. Entrance Scholarships in Medicine.—One Scholarship in each year will be offered for proficiency in Arts and one for proficiency in Science. The Scholarships are of the value of £100 each, which will be set off against their fees as follows: £60 against the fees and £40 against the Infirmary fees. Platt Biological Scholarship.—£50 for one year, awarded to the candidate who shows the most promise and ability for prosecuting original research in Zoology and Botany. Dauntesey Medical Scholarships.—Two Scholarships of £35 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the University or any other Medical School in the United Kingdom. Candidates will be examined in Zoology, Botany, and Chemistry. Medals are awarded on the results of the various class examinations at the end of each session. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the competition of persons whether previously students of the University or not. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology, and a Sidney Renshaw Exhibition in Physiology of the value of £15 to be competed for by second year students in Physiology. A Professor Tom Jones Memorial Exhibition of the value of £25, a Dumville Surgical Prize of £15, a Turner Medical Scholarship of £20, and a John Henry Agnew Scholarship in Diseases of Children of £30 are offered annually for competition. A Professor Tom Jones Memorial Scholarship of £100 is awarded triennially, a Bradley Memorial Scholarship in Clinical Surgery of the value of £20 and Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

THE MANCHESTER ROYAL INFIRMARY.—The medical students of the Victoria University of Manchester receive their clinical instruction at the hospital. The hospital contains 292 beds, with an annual average number of over 5000 inpatients. The annual average number of out- and home-patients is 29,000, and the list of casualties dealt with in the accident room exceeds 14,000 per annum. About 2800 operations are performed annually in the operation theatres. It is expected that the new infirmary, built on the Stanley Grove estate, to accommodate 600 in-patients, will be opened at the commencement of the Winter Session next year. Associated with the infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds; and (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients. The associated hospitals thus contain 858 beds and are under the same management. Women students are admitted to the practice of the infirmary on the same terms as men, except in the surgical out-patient department. A valuable Medical Reference Library is accessible to students. In addition to the list of scholarships tabulated in another column, two Entrance Scholarships in Medicine of the value of £100 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. The Bradley Memorial Scholarship in Clinical Surgery, value £20, is offered annually in the Summer Session. Gentlemen are eligible who are in their fifth or sixth year of study, have com-
pleted their dresserships, and have spent two years in clinical work at the Manchester Royal Infirmary. One Medical and one Surgical Clinical Prize of the value of 6 guineas are offered annually. (The other scholarships and prizes are in the College Syllabus.) Annual appointments may be held by those who have attended the practice of the infirmary: a Surgical Registrar (£80); a Pathological Registrar (£100); a Medical Registrar (£70); a Surgical Tutor (£30); a Director of the Clinical Laboratory (£200); an Assistant Medical Officer and an Assistant Surgical Officer (£50 each); an Anæsthetist (£50); an Assistant Anæsthetist (£50); a Medical Officer for home patients (£150). A Third Anæsthetist is appointed for six months (30 guineas) and an Accident House Surgeon is appointed for three months (20 guineas). The following resident appointments are also made annually: Resident Medical Officer (£150); Resident Surgical Officer (£150); Resident Medical Officer at the Convalescent Hospital at Cheadle (£150). An Assistant Medical Officer at this hospital is appointed every six months at a salary of £80 per annum. The following unpaid appointments are open to those who have attended the practice of the Infirmary:—House Surgeons: Two House Surgeons are appointed every three months for a term of six months. House Physicians: Two House Physicians are appointed every three months for a term of six months. The House Surgeons and House Physicians and Resident Assistant at Cheadle must possess registrable qualifications. Consulting Physician: Dr. Henry Simpson. Consulting Surgeons: Mr. Walter Whitehead and Mr. James Hardie. Physicians: Dr. Graham Steell, Dr. J. S. Bury, Dr. A. T. Wilkinson, and Dr. E. S. Reynolds. Assistant Physicians: Dr. R. T. Williamson, Dr. E. M. Brockbank, and Dr. E. N. Cunliffe. Pathologist: Dr. J. Lorrain Smith. Consulting Obstetric Physician: Dr. Lloyd Roberts. Gynæcological Surgeon: Dr. Archibald Donald. Surgeons: Mr. F. A. Southam, Mr. G. A. Wright, Mr. William Thorburn, and Mr. J. E. Platt. Assistant Surgeons: Mr. W. P. Montgomery, Mr. J. W. Smith, Mr. A. H. Burgess, and Mr. J. H. Ray. Ophthalmic Surgeon: Dr. Hill Griffith. Aural Surgeon: Dr. William Milligan. Anæsthetist: Mr. Alex. Wilson. Consulting Dental Surgeon: Mr. G. W. Smith. Dental Surgeon: Mr. W. A. Hooton. Pathological Registrar: Dr. W. B. Anderton. Medical Registrar: Dr. A. Ramsbottom. Surgical Registrar: Mr. A. E. Johnson. Director of the Clinical Laboratory: Dr. G. E. Loveday. Assistant Director of the Clinical Labora-
tory: Dr. A. Ramsbottom. Administrators of Anæsthetics: Mr. W. J. S. Bythell and Mr. A. F. Thompson. Assistant Medical Officer for Out-patients: Dr. J. D'Ewart. Assistant Surgical Officers for Out-patients: Mr. O. Roberts, Mr. E. D. Telford, and Mr. P. R. Wrigley. Medical Officer for Home Patients: Dr. George Ashton. General Superinten-
dent and Secretary: Mr. Walter G. Carnt. The Winter Session commences Oct. 1st.

There are other institutions at which the student of medicine of the University of Manchester can receive clinical instruction.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury and Gartside-street, Manchester.—The hospital contains 168 beds and 24 in the Convalescent Home, St. Anne's-on-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the new Out-patient Department, Gartside-street, Manchester. Physicians: Dr. Ashby, Dr. Hutton, and Dr. Heywood. Surgeons: Mr. J. Howson Ray, Mr. E. D. Telford, and Mr. C. Roberts. Honorary Consulting Surgeon: Mr. G. A. Wright. Honorary Consulting Pathologist: Professor R. Lorrain Smith. Anæsthetist: Mr. Harold Snape. Honorary Surgeon for Throat, Nose, and Ear Diseases: Mr. F. H. Westmacott. Pathologist: Dr. W. Mair. Honorary Dental Surgeon: Mr. Barron J. Rodway. Resident Medical Officers: Mr. E. E. Hughes and Mr. T. M. Bride. Medical Officers at the Dispensary: Dr. C. P. Lapage and Mr. R. H. Swindells. During 1906 there were 2235 in-patients and 25,323 new out-patients were under treatment at the Dis-
pensary, and there were 77,857 attendances made by out-
patients. Secretary: Mr. H. J. Eason.

THE MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham-hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M. Honorary Consulting Physicians: Dr. W. N. Maccall, Dr. S. Holgate Owen, and Dr. T. C. Railton. Honorary Consulting Surgeons: Mr. James Hardie and Mr. Frederick A. Southam. Honorary Physicians for Women: Dr. Samuel Buckley and Dr. T. Arthur Helme. Honorary Surgeon for Women: Mr. Arnold W. W. Lea. Honorary Physician: Dr. J. J. Cox. Honorary Assistant Physician: Dr. W. E. Fothergill. Honorary Assistant Physicians for Children: Dr. C. H. Melland and Dr. C. C. Heywood. Honorary Surgeon for Children: Mr. Charles Roberts.

of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. Additional rooms for the Students' Union have recently been added, viz.: (*a*) a large reading and smoking room; (*b*) a committee and writing room; and (*c*) luncheon and dining hall. There are in the new block.

Staff.—Consulting Physicians: Sir William S. Church, Bart., K.C.B., Dr. Hensley, Sir Lauder Brunton, F.R.S., Dr. Gee, and Sir Dyce Duckworth. Consulting Surgeons: Sir Thomas Smith, Bart., K.C.V.O., Mr. Willett, Mr. Butlin, Mr. Marsh, and Mr. Langton. Consulting Ophthalmic Surgeon: Mr. Henry Power. Physicians: Dr. Norman Moore, Dr. Samuel West, Dr. Ormerod, Dr. Herringham, and Dr. Tooth, C.M.G. Surgeons: Mr. Harrison Cripps, Mr. Bruce Clarke, Mr. Anthony Bowlby, C.M.G., Mr. Lockwood, and Mr. D'Arcy Power. Assistant Physicians: Dr. Garrod, Dr. Calvert, Dr. Morley Fletcher, Dr. Drysdale, and Dr. Horton-Smith-Hartley. Assistant Surgeons: Mr. Waring, Mr. Eccles, Mr. Bailey, Mr. Rawling, and Mr. Gask. Physician Accoucheur: Dr. Champneys. Physician Accoucheur with charge of out-patients: Dr. W. S. A. Griffith. Surgeon to Obstetric Wards: Mr. Harrison Cripps. Assistant Physician Accoucheur: Dr. Williamson. Ophthalmic Surgeons: Mr. Jessop and Mr. Holmes Spicer. Aural Surgeon: Mr. Cumberbatch. Assistant Aural Surgeon: Mr. C. E. West. Dental Surgeons: Mr. Paterson and Mr. Ackland. Assistant Dental Surgeons: Dr. Austen and Mr. Coleman. Medical Officer in charge of Electrical Department: Dr. Lewis Jones. Pathologist: Dr. Andrewes. Administrators of Anæsthetics: Mr. Gill and Mr. Cross. Assistant Administrator of Anæsthetics: Mr. Boyle. Medical Registrars: Dr. Horder and Dr. Langdon Brown. Surgical Registrar: Mr. Gordon Watson. Casualty Physicians: Dr. Hudson and Dr. Pritchard.

Lectures and Demonstrations.—Medicine: Dr. Norman Moore and Dr. S. West. Clinical Medicine: Dr. Norman Moore, Dr. S. West, Dr. J. A. Ormerod, Dr. W. P. Herringham, and Dr. H. H. Tooth. Practical Medicine: Dr. J. H. Drysdale and Dr. Horton-Smith-Hartley. Surgery: Mr. W. Bruce Clarke and Mr. D'Arcy Power. Clinical Surgery: Mr. Harrison Cripps, Mr. W. Bruce Clarke, Mr. Anthony Bowlby, Mr. C. B. Lockwood, and Mr. D'Arcy Power. Practical Surgery: Mr. R. C. Bailey and Mr. L. B. Rawling. Operative Surgery: Mr. R. C. Bailey, Mr. W. McAdam Eccles, and Mr. L. B. Rawling. Midwifery and the Diseases of Women and Children: Dr. F. H. Champneys. Practical Midwifery: Dr. J. A. Willett. Pathology: Dr. F. W. Andrewes. Bacteriology (advanced): Dr. E. E. Klein. Chemical Pathology: Dr. A. E. Garrod. Morbid Anatomy and Post Mortems: Dr. T. J. Horder, Dr. Langdon Brown, and Mr. Watson. Practical Pathology: Mr. F. A. Rose, Dr. H. Thursfield, Mr. R. C. Elmslie, and Dr. Neligan. Ophthalmic Medicine and Surgery: Mr. W. H. Jessop. Diseases of the Eye: Mr. W. H. Jessop and Mr. W. Holmes Spicer. Ophthalmic Demonstrations: Mr. W. Holmes Spicer. Diseases of the Ear: Mr. A. E. Cumberbatch and Mr. C. E. West. Diseases of the Larynx: Mr. W. D. Harmer and Mr. F. E. Rose. Orthopædic Surgery: Mr. W. MacAdam Eccles. Diseases of the Skin: Dr. J. A. Ormerod. Diseases of Children: Dr. A. E. Garrod and Dr. H. Morley Fletcher. Medical Electricity and Electro-therapeutics: Dr. H. Lewis Jones. Mental Diseases and Insanity: Dr. T. Claye Shaw. Dental Surgery: Mr. W. B. Paterson and Mr. R. C. Ackland. Anæsthetics: Mr. R. Gill, Mr. W. F. Cross, and Mr. H. E. G. Boyle. Forensic Medicine: Dr. W. P. Herringham. Descriptive and Surgical Anatomy: Dr. C. Addison. Practical Anatomy: Dr. C. Addison, Mr. C. G. Watson, Mr. R. B. Etherington-Smith, and Mr. H. W. Wilson. General Anatomy and Physiology: Dr. J. S. Edkins. Practical Physiology: Dr. J. S. Edkins, Dr. W. Langdon Brown, and Dr. C. M. H. Howell. Materia Medica, Pharmacology, and Therapeutics: Dr. James Calvert. Pharmacology: Dr. F. A. Bainbridge. Biology and Comparative Anatomy: Dr. T. W. Shore. Practical Biology: Dr. T. W. Shore, Mr. T. S. Lukis, and Mr. C. T. Neve. Chemistry: Dr. W. H. Hurtley. Practical Chemistry: Dr. W. H. Hurtley and Mr. K. S. Caldwell. Physics: Mr. F. Womack. Practical Physics: Mr. F. Womack and Mr. Lloyd Hopwood. Botany: Rev. G. Henslow. Public Health: Dr. George Newman. Sanitary Law: Dr. G. Newman. Museum Curator: Dr. F. W. Andrewes. Junior Curator: Dr. W. P. S. Branson. Dean of the School: Dr. T. W. Shore. Warden of College: Mr. G. E. Gask.

CHARING CROSS HOSPITAL.—This hospital and convalescent home contain 287 beds, a certain proportion of which are set aside for the diseases of children and those special to women. The number of patients treated during 1906 amounted to 24,631—viz., 2539 in-patients and 22,142 out-patients, (of whom 10,390 were casualties. There were 70,186 out-patient attendances. The following hospital appointments are open to students. Clinical Pathologist and Bacteriologist, salary £150 per annum. Curator and Pathologist (annual), £100. Assistant Anæsthetist, £60. Medical and Surgical and Obstetrical Registrars (annual), £40 each. Resident Medical Officer (annual), £100, with board and residence. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers, appointed each year on the recommendation of the committee after competitive examinations, are provided with board and residence in the hospital. Clinical clerks and dressers are appointed in all the general and special departments of the hospital. Arrangements can be made for students who have not entered for the entire curriculum to hold these posts. In the medical school demonstratorships and assistant demonstratorships in *various subjects are open to students of the school* and carry honoraria. Total fees, including students' club:—For general students: 1. Composition fee, payable in one sum on joining, 115 guineas. 2. Sessional payment system: Entrance fee, 10 guineas. In addition a sum of 15 guineas must be paid at the beginning of every Winter Session and one of 10 guineas at the beginning of every Summer Session so long as the student remains in the school. For Dental students: The fees for the two years' curriculum required by dental students may be paid: (*a*) in one sum of 55 guineas on entry; (*b*) in two instalments, one of 31 guineas on entry and the second of 30 guineas at the end of the first twelve months. General students pay proportionally lower fees and are admitted without additional fee to the courses of Clinical Medicine and Surgery. They are entitled to compete for the Scholarships which are awarded annually to the value of £575, including two University Scholarships, value 72 guineas each, Gold Medal, Huxley, and Pereira Prizes.

Classes for the *Preliminary Scientific and Intermediate Examinations* of the University of London and for the Primary F.R.C.S. are held at this Medical School. There are also special classes for the practical work for the Department of Public Health and for the Primary F.R.C.S.

Staff.—Consulting Physicians: Dr. Green, Dr. Bruce, and Dr. Abercrombie. Consulting Obstetric Physician: Dr. J. Watt Black. Physicians: Dr. Murray, Dr. Mott, and Dr. Galloway. Assistant Physicians: Dr. Hunter, Dr. Bosanquet, Dr. Fenton, and Dr. Forsyth. Consulting Surgeons: Mr. R. Barwell, Mr. Bloxam, and Mr. Morgan, C.V.O. Surgeons: Mr. Boyd, Mr. Waterhouse, and Mr. Wallis. Surgeon to Out-patients: Mr. Gibbs. Assistant Surgeons: Mr. Clogg and Mr. Daniel. Obstetric Physician: Dr. Amand Routh. Assistant Obstetric Physician: Dr. T. W. Eden. Physician for Diseases of the Skin: Dr. Galloway. Assistant Physician for Diseases of the Skin: Dr. MacLeod. Physician to the Electrical Department: Dr. Ironside Bruce. Surgeon for Nose, Throat, and Ear: Mr. Waggett. Ophthalmic Surgeon: Mr. Treacher Collins. Orthopædic Surgeon: Mr. Fairbank. Surgeon Dentist: Mr. J. F. Colyer. Physician for Mental Diseases: Dr. Mercier.

Lecturers: Winter Session.—Anatomy: Dr. Alexander Macphail. Bacteriology: Mr. Leathem. Biology and Comparative Anatomy: Dr. H. W. Marett Tims. Chemistry and Physics: Dr. H. Forster Morley. Dental Surgery: Mr. J. F. Colyer. Medicine: Dr. H. Montague Murray and Dr. F. W. Mott. Ophthalmology: Mr. E. Treacher Collins. Physiology and Histology: Mr. C. F. Myers-Ward. Practical Anæsthetics: Mr. C. Carter Braine. Practical Anatomy: Dr. Alexander Macphail. Practical Hygiene: Mr. Leathem and Dr. H. Forster Morley. Practical Medicine: Dr. Bosanquet and Dr. Forsyth. Diseases of Women: Dr. Amand Routh. Practical Midwifery: Dr. T. W. Eden. Practical Physiology: Mr. C. F. Myers-Ward. Practical Surgery: Mr. F. C. Wallis, Mr. H. S. Clogg, and Mr. Fairbank. Operative Surgery: Mr. Charles Gibbs. Psychological Medicine: Dr. Mercier. Surgery: Mr. H. F. Waterhouse. Tropical Medicine: Sir Patrick Manson.

Summer Session.—Anatomy: Dr. Alexander Macphail.

numerous articles in the scientific press. From the beginning of this year, however, the memoirs have been succeeded by the "Annals of Tropical Medicine and Parasitology," published by the Committee and open to outside contributors (apply to the Secretary, B 10, Exchange-buildings, Liverpool). The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine, and has been given to Colonel Bruce, Professor Koch, Dr. Laveran, and Sir Patrick Manson.

The Liverpool Clinical School of Medicine consists, as we have already said, of four general hospitals and five special hospitals, which in the aggregate contain 1127 beds. The former are the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital. The latter are the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye and Ear Hospital, and St. George's Hospital for Skin Diseases.

School of Veterinary Medicine.—A school of Veterinary Medicine in connexion with the University was opened in October, 1904; full courses of instruction for the Veterinary Curriculum will be provided and students will be prepared for the M.R.C.V.S. A diploma in Veterinary Hygiene is now granted by the University.

Public Health Department.—This is located in a separate building known as Ashton Hall in which full courses of instruction are given to D.P.H. students for the D.P.H. of the University.

Special Diplomas.—The University has instituted diplomas in Anatomy, Bacteriology, Bio-chemistry, and Parasitology. A special course of study of three terms' duration is required in the subject chosen for the diploma and allied subjects.

School of Pharmacy.—Complete courses of instruction are provided adapted to the requirements of candidates preparing for either the Minor or Major Examinations of the Pharmaceutical Society of Great Britain.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

Royal Infirmary Staff.—Consulting Physicians: Dr. A. T. H. Waters, Dr. T. R. Glynn, and Dr R. Caton. Physicians: Sir James Barr, M.D., Dr. T. R. Bradshaw, and Dr. J. H. Abram. Assistant Physicians: Dr. R. J. M. Buchanan and Dr. E. Glynn. Consulting Surgeon: Mr. E. E. Bickersteth. Surgeons: Mr. R. Parker, Mr. F. T. Paul, and Mr. G. G. Hamilton. Assistant Surgeons: Mr R. A. Bickersteth, Mr. W. T. Thomas, and Mr. T. O. Littler-Jones. Gynæcological Surgeon: Mr. T. B. Grimsdale. Assistant Gynæcological Surgeon: Mr. W. B. Bell. Ophthalmic Surgeon: Mr. T. H. Bickerton. Surgeon to the Throat Department: Mr. J. M. Hunt. Physician to the Skin Department: Dr. L. Roberts. Dental Surgeon: Mr. E. J. M. Phillips. Pathologists: Sir R. W. Boyce and Dr. E. Glynn. Anæsthetists: Mr. W. Fingland, Mr. F. W. Bailey, Mr. H. Armstrong, and Mr. A J. O'Leary.

David Lewis Northern Hospital Staff.—Physicians: Dr. T. Bushby and Dr. W. T. Warrington. Consulting Surgeons: Mr. W. M. Campbell and Mr. C. Puzey. Surgeons: Mr. D. Harrison, Mr. R. Murray, and Mr. K. W. Monsarrat. Consulting Ophthalmic Surgeon: Mr. G. E. Walker. Radiologist: Dr. J. N. Walker. Surgeon to the Orthopædic Department: Mr. E. Broad. Dental Surgeon: Mr. W. Matthews. Pathologist: Dr. J. Owen. Bacteriologist: Dr. C. A. Hill. Anæsthetists: Mr. G. B. Robinson, Mr. R. Stevenson, and Mr. V. C. de Boinville.

Royal Southern Hospital Staff.—Consulting Physicians: Dr. J. Cameron and Dr. W. Williams. Consulting Surgeon: Mr. R. Hamilton. Physicians: Dr. W. Carter, Dr. J. W. MacAllister, and Dr. J. L. Roberts. Surgeons: Mr. W. Alexander, Mr. R. Jones, and Mr. G. P. Newbolt. Physician to the Skin Department: Dr. F. H. Barendt. Consulting Ophthalmic Surgeon: Mr. R Williams. Consulting Aural Surgeon: Mr. G. O. Lee. Consulting Physician for Tropical Diseases: Dr. R. Ross. Consulting Surgeon to the Throat Department: Mr. W. Permewan. Radiologist: Dr. D. Morgan. Dental Surgeon: Mr. J. Royston. Anæsthetists: Mr. A. J. Evans, Mr. D. M. Alexander, and Mr. F. M. Gardner-Medwin.

Stanley Hospital Staff.—Consulting Physician: Dr. R. J. Richardson. Consulting Surgeons: Mr. J. Bark and Mr. K. A. Grossmann. Physicians: Dr. W. Whitford, Dr. A. G. Gullan, and Dr. J. Hay. Surgeons: Mr. F. C. Larkin and Mr. D. Douglas-Crawford. Ophthalmic Physician: Dr. R. J. Hamilton. Laryngologist: Mr. J. Bark. Assistant Laryngologist: Mr. J. E. McDougall. Physician for Skin Diseases: Dr. W. Whitford. Dentist: Mr. J. H. Burroughs.

THE UNIVERSITY OF BIRMINGHAM: MEDICAL FACULTY.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital, details of which follow. The students can be members of the University Club, the University Athletic Club, and the University Volunteer Company, while they possess a guild—the Guild of Undergraduates—which is designed to be a recognised medium of communication between the teachers and the taught. The University Medical Society and the Dental Students' Society also offer opportunities of coöperation for mutual benefit. The scholarships and prizes are tabulated in another column.

The clinical instruction of the Birmingham medical students is carried on under the direction of the Birmingham Clinical Board. The hospitals present an excellent field for clinical work, possessing more than 450 beds, treating annually 8000 in-patients and 80,000 out-patients. The students spend part of their curriculum in each hospital, and thus have every opportunity of acquiring a varied, full, and practical knowledge of their professional work. The curriculum is adapted in the first place to meet the needs of the students of the University of Birmingham, but it is also well adapted to the requirements of students preparing for the examinations of all other universities and licensing bodies. At the General Hospital there are open to the students the following appointments: A resident medical officer, elected annually (£70); a resident surgical officer, elected annually and eligible for re-election for three years (£100); a resident pathologist, elected for six months (£50); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £50 a year; one house surgeon to the gynæcological, ophthalmic, and aural departments is elected every six months, receiving board, residence, and a salary of £50 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year; a resident medical officer at the Jaffray Hospital, who is elected annually but is eligible for re-election, and who receives £150 a year; and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £50 a year. Thirty-five other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Lunatic Asylums, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopædic and Spinal Hospital, and at the Ear and Throat Hospital.

The General Hospital contains 342 beds, and of these 327 are in daily use, upwards of 5000 in-patients passing through the wards in the course of a year. There are special wards for children, for gynæcological cases, and for septic and infectious cases, and in addition special beds reserved for eye and ear cases. Some 60,000 out-patients are treated there annually. The post-mortem department is in a separate building. It consists of a mortuary with a small chapel, a post-mortem room proper, and laboratories for bacteriology and morbid histology. In addition there are separate rooms in the main building, adjoining the various medical and surgical wards, for clinical pathology and these are under the direction of special officers. There are four operating theatres, all designed and fitted on the most modern lines. In connexion with the hospital is the Jaffray Suburban Hospital of 52 beds at Gravelly Hill. The arrangements for clinical teaching at this hospital are very thorough. In addition to the clinical teaching given in the wards and out-patient department by the honorary staff medical and tutorial classes are held for senior and junior students, while clinical instruction is given in all the special departments by the gentlemen in charge of them.

Staff of General Hospital.—Consulting Physicians: Sir Walter Foster and Dr. Edwin Rickards. Consulting Obstetric Officer:

Mann. Surgery: Mr. Golding-Bird, Mr. Symonds, Mr. Lane, and Mr. Dunn. Operative Surgery: Sir Alfred Fripp and Mr. Steward. Practical Surgery: Mr. Hamilton and Mr. Bankart. Midwifery and Diseases of Women: Dr. Horrocks and Mr. Targett. Practical Obstetrics: Mr. Davies-Colley. Mental Diseases: Dr. Craig. Ophthalmic Surgery: Mr. Eason. Dental Surgery: Mr. Wynne Rouw. Aural Surgery: Mr. Fagge. Diseases of the Skin: Sir Cooper Perry. Diseases of the Throat: Mr. Steward. Anæsthetics: Mr. Rowell. Hygiene and Public Health: Dr. R. King Brown. Pathology: Dr. A. E. Boycott. Gordon Lecturer on Experimental Pathology: Dr. Boycott. Morbid Anatomy: Dr. Fawcett and Dr. French. Morbid Histology and Bacteriology: Dr. Eyre and Dr. Boycott. Medical and Surgical Pathology Classes: Dr. Fawcett and Mr. Steward. Bacteriology: Dr. Eyre. Practical Bacteriology: Dr. Eyre. Forensic Medicine: Sir Thomas Stevenson, M.D. Anatomy: Sir Alfred Fripp and Mr. Steward. Practical Anatomy: Mr. P. Turner, Mr. W. M. Mollison, and Dr. A. R. Thompson. Physiology: Dr. Pembrey. Practical Physiology: Dr. Pembrey, Mr. J. H. Ryffel, B.Sc., and Mr. P. P. Laidlow, B.O. Materia Medica and Therapeutics: Dr. A. P. Beddard. Practical Pharmacy: the Hospital Pharmacist. Chemistry: Dr. Wade. Practical Chemistry: Dr. Wade, Mr. Ball, and Mr. Merriman. Experimental Physics: Dr. Fison and Mr. Merriman. Biology: Mr. Assheton, Dr. Stevens, and Mr. Thompson. Psychology: Dr. Craig.

King's College and Hospital.—The Faculty of Medicine at King's College is now divided into two parts; the first is concerned with Preliminary and Intermediate subjects and instruction on these is given in the College laboratories. This department is now designated Faculty of Science (Medical Division); the second deals with the Advanced or Final subjects of the curriculum, instruction on which is given at the hospital, except in subjects like Bacteriology where laboratory courses are necessary.

In the Faculty of Science (Medical Division) the following are the:—

Lecturers on Preliminary and Intermediate Subjects.—Anatomy: Dr. P. Thompson (Professor), Dr. C. J. Jenkins (Lecturer), and Mr. J. E. S. Frazer (Demonstrator). Physiology: Dr. W. D. Halliburton (Professor), Dr. H. W. Lyle (Lecturer), Dr. O. Rosenheim (Lecturer on Chemical Physiology), and Dr. C. S. Myers (Lecturer on Experimental Psychology). Zoology: Dr. A. Dendy (Professor). Botany: Dr. W. B. Bottomley (Professor) and Mr. E. J. Schwartz (Demonstrator). Chemistry: Dr. J. M. Thomson (Professor), Mr. H. Jackson (Assistant Professor), and Mr. P. H. Kirkaldy (Lecturer). Physics: Dr. Wilson. Materia Medica and Pharmacology: Dr. W. E. Dixon (Professor).

Fees.—For London University Course: for Preliminary Scientific (Part I.), 25 guineas; for Preliminary Scientific (Part II.) and Intermediate M.B., 55 guineas, or two instalments of 30 guineas each. For Conjoint Board Course: for First examination, 20 guineas; for Second examination, 55 guineas, or two instalments of 30 guineas each. For prospectus and further information application should be made to Dr. P. Thompson, Dean of the department.

The advanced or final subjects in the curriculum are dealt with at the Medical School attached to King's College Hospital. The hospital contains 224 beds. 3000 in-patients, 16,000 new out-patient cases, 40,600 casualties, and about 350 midwifery cases are attended yearly. The hospital contains special departments for diseases of women and children, and of the eye, ear, throat and nose, skin and teeth. There are special operation theatres for diseases of women, for eye, and for throat, nose, and ear cases. There is a clinical pathologist and a laboratory in the hospital where histological, bacteriological, hæmatological, and chemical investigations are carried out. In connexion with this is a vaccine department for the treatment of patients suffering from tuberculosis and other infective diseases. The appointments open to students are those of senior clinical assistant to the special departments; senior medical, surgical, and obstetric registrar; and Sambrooke medical and surgical registrars, all of whom receive salaries, as do the medical and surgical tutors. There are 14 resident medical and surgical officers appointed yearly and the usual six senior surgical dressers, medical and obstetric clinical clerks, surgical dressers, and clerks and dressers in all the special departments for in- and out-patients, and post-mortem clerks.

Hospital Staff.—Consulting Physicians: Sir A. B. Garrod, Dr. Alfred B. Duffin, and Dr. I. Burney Yeo. Consulting Surgeons: Lord Lister and Mr. W. Rose. Physicians: Dr. David Ferrier, Dr. Nestor Tirard, Dr. Norman Dalton, Sir Hugh Beevor, Bart., and Dr. Raymond Crawfurd. Surgeons: Mr. W. Watson Cheyne, Mr. A. B. Barrow, Mr. A. Carless, Mr. F. F. Burghard, Mr. G. L. Cheatle, and Mr. P. T. B. Beale. Assistant Physicians: Dr. W. Aldren Turner and Dr. Tunnicliffe. Obstetric Physician: Dr. John Phillips. Assistant Obstetric Physician: Dr. Hugh Playfair. Physician for the Diseases of Children: Dr. George F. Still. Diseases of the Throat: Dr. StClair Thomson. Dental Surgeon: Mr. A. S. Underwood. Assistant Dental Surgeon: Mr. O. E. Wallis. Ophthalmic Surgeons: Mr. M. M. McHardy and Mr. L. V. Cargill. Aural Surgeons: Dr. Urban Pritchard and Mr. Arthur H. Cheatle. Physician for Diseases of the Skin: Dr. A. Whitfield. Pathological Registrar: Dr. Norman Dalton. Physician in charge of Electrical Department: Dr. W. Aldren Turner. Medical Officer in charge of X Ray Department: Mr. A. D. Reid. Anæsthetist and Instructor in Anæsthetics: Dr. J. F. W. Silk. Assistant Anæsthetist: Dr. G. B. Flux. Clinical Pathologist: Dr. Emery. Senior Medical Registrar and Tutor: Dr. J. O. Briscoe. Senior Surgical Registrar and Tutor: Dr. T. Percy Legg. Obstetric Registrar and Tutor: Dr. G. de B. Turtle. Sambrooke Registrars: Mr. H. W. Wiltshire and Mr. R. H. Gompertz.

Lecturers on Final Subjects.—Medicine (Principles and Practice of): Dr. Nestor Tirard (Professor). Neuro-Pathology: Dr. D. Ferrier (Professor) and Dr. W. A. Turner (Demonstrator). Psychological Medicine: Dr. Ernest W. White (Professor). Surgery (Principles and Practice of): Mr. A. Carless (Professor). Surgery (Operative): Mr. F. F. Burghard (Teacher). Surgical Pathology: Mr. G. L. Cheatle (Teacher). Obstetric Medicine and Diseases of Women and Children: Dr. John Phillips (Professor). Practical Obstetrics: Dr. Hugh Playfair (Lecturer). Diseases of Children: Dr. G. F. Still (Professor). Pathology: Dr. N. Dalton (Professor). Forensic Medicine: Dr. W. R. Smith (Professor). Hygiene: Dr. W. J. R. Simpson (Professor). State Medicine: Dr. Hewlett (Professor) and Mr. D. Somerville (Demonstrator). Bacteriology: Dr. Hewlett (Professor) and Dr. F. E. Taylor. Ophthalmic Surgery: Mr. M. M. McHardy (Professor). Aural Surgery: Dr. Urban Pritchard (Professor). Dermatology: Dr. A. Whitfield (Professor). Anæsthetics: Dr. J. F. W. Silk. Dental Surgery: Mr. A. S. Underwood (Professor). Diseases of the Skin: Dr. A. Whitfield (Physician).

Fees.—The composition fee for Hospital work and Final subjects of the curriculum is 70 guineas in one sum or in two equal instalments of 36 guineas payable on entrance and on commencement of second year of study respectively. For information and prospectus application should be made to Peyton T. B. Beale, F.R C.S., Dean of the Hospital. For information regarding fees, curriculum, &c., in Public Health and Bacteriology application should be made to Professor Hewlett.

Athletic Club.—All students are entitled to the privileges of the Athletic Club, which manages a large recreation ground of the College at Wormwood Scrubs.

London Hospital.—The hospital has 914 beds in constant use and no beds are closed. Being the only general hospital for East London—i.e., for a million and a half people—the practice is immense. In-patients last year, 14,139; out-patients, 229,408; accidents, 15,779; major operations, 3368. Owing to the enormous number of patients more appointments are open to students than at any other hospital. Receiving-room officers, house physicians, house surgeons, &c.: 90 of these qualified appointments are made annually and more than 150 dressers, clinical clerks, &c., appointed every three months. All are free to students of the College. Holders of resident appointments have free board. Special classes are held for the University of London and other higher examinations. Special entries for medical and surgical practice can be made. Lectures and classes are held throughout the year to suit the requirements of candidates desirous of obtaining the diploma in Public Health. The Lecturer on Public Health given at either institution by the Anæsthetists. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—which are in the University buildings are, both as regards structural arrangements and scientific equipment, on the most modern and complete lines. No expense has been spared in the matter of apparatus for teaching or research work and the facilities for practical study in these subjects are second to none. The department of Pathology and Bacteriology in the University is replete with every requirement for the most advanced work in these subjects. There is a large Pathological Museum in the department open daily to students. The post-mortem rooms of the Royal Infirmary and Royal Hospital are under the charge of the Professor of Pathology and afford ample material for demonstrations. In connexion with the University there is a complete dental department, fully recognised by the various examining bodies, at the Sheffield Royal Hospital. A list of the various Scholarships and Fellowships will be found in another column.

Students who have passed their examination in anatomy and physiology can hold the usual dresserships and clerkships, the appointments being for a period of three months except in the case of casualty dresserships, which last two months. All students beginning hospital practice in Sheffield will be required to hold the post of casualty dresser before being eligible for any other of the above appointments. In addition to the laboratories above mentioned the Medical department of the University contains lecture rooms for the various subjects of the curriculum, a complete materia medica museum, and the large library and reading-room of the Medico-Chirurgical Society which is open daily to students for purposes of study.

Fees.—Composition fee of £80, payable in three instalments—viz., £24 at commencement for first year of study, £28 at commencement of second year of study, and £28 at commencement of third year of study. A composition fee of £80 entitles the student to attendance on all the courses of lectures and practical classes except pharmacy, vaccination, and instruction in anæsthetics required for a degree course in the University or for the ordinary qualifications in medicine and surgery of the Examining Boards. The composition fee does not include medical and surgical hospital practice, clinical lectures, practical instruction in mental diseases, diseases of women, and infectious diseases, the fee for the full period of both medical and surgical hospital practice required by the Examining Boards being £36 15*s.* if paid in one sum at commencement of hospital practice; or £37 16*s.* if paid in two sums of £18 18*s.*, one on beginning hospital practice the other twelve months later.

The various athletic and other students' societies are under the management of a students' representative council, elected annually. There are large and comfortable common rooms both for men and women students. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal *Floreamus*, edited by a committee of staff and students, is published each term. The St. Peter's Hostel, Ashgate-road, is recognised by the Senate as a residence for women students, full particulars of which may be obtained of the Lady Tutor. Other societies of interest to the medical student are the Biological, Chemical, and Clinical and Pathological Societies.

Staff of the Sheffield Royal Infirmary.—Physicians: Dr. W. Dyson, B.A., Dr. W. S. Porter, and Dr. W. Tusting Cocking. Surgeons: Mr. Sinclair White, Mr. Arthur Connell, and Mr. Archibald Cuff. *Ophthalmic Surgeon:* Mr. Simeon Snell. *Medical Officer to the Skin Department:* Dr. W. Tusting Cocking. Medical Officer to the Ear and Throat Department: Mr. W. S. Kerr. Pathologist: Professor J. M. Beattie. Medical Officer in Charge of Electrical Department: Dr. A. Rupert Hallam. Anæsthetists: Mr. H. T. Wightman, Mr. J. Wilfred Stokes, and Dr. A. Rupert Hallam. Honorary Secretary to the Medical and Surgical Staff: Mr. Arthur Connell.

Staff of the Sheffield Royal Hospital.—Physicians: Dr. Duncan Burgess and Dr. Arthur Hall. Surgeons: Mr. R. J. Pye-Smith, Mr. H Lockwood, and Mr. G. Wilkinson. Ophthalmic Surgeon: Dr. S. Riseley. Physician for Mental Diseases: Mr. G. E. Mould. Assistant Surgeon: Mr. G. Simpson. Assistant Physicians for Outpatients: Dr. A. E. Naish and Dr. A. Young. Anæsthetists: Mr. H. Hallam, Mr. N. Milner, and Dr. G. Murray. Medical Officer to the Electrical and X Ray Department: Dr. W. H. Nutt. Pathologist: Professor J. M. Beattie. Honorary Secretary to the Medical and Surgical Staff: Dr. S. Riseley. Dental Surgeons: Mr. C. Stokes, Mr. F. G. Mordaunt, Mr. F. Harrison, Mr. D. Dathl Davies, and Mr. H. J. Morris. Assistant Dental Surgeons: Mr. C. C. Drabble, Mr. H. J. Stoner, Mr. P. Southwell Stokes, and Mr. W. J. Law.

There are other institutions at which the students of the University of Sheffield can receive clinical instruction. These are the City Fever Hospitals (Medical Superintendent, Dr. Egerton H. Williams), the South Yorkshire Asylum (Medical Superintendent, Dr. W. S. Kay), and the Jessop Hospital for Women, Gell-street, Sheffield. The hospital contains 54 beds for gynæcological cases and 18 for obstetric cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and, in case of need, are assisted by the members of the medical staff. A 12 weeks' course of instruction (theoretical and practical) is also provided for resident and non-resident pupil midwives, the institution being approved by the Central Midwives Board as a training centre. Medical Officers: Mr. Richard Favell, Dr. J. W. Martin, and Mr. Percival E. Barber. Assistant Medical Officer: Mr. M. H. Phillips. Honorary Secretary to the Staff: Mr. Percival E. Barber.

OTHER PROVINCIAL MEDICAL SCHOOLS.

THE institutions which follow provide facilities for different forms of clinical instruction for the medical student or medical graduate. For the most part they are the general hospitals of large towns which are not, at any rate, yet the seat of a university. There are university colleges at Bristol and at Cardiff, and at both cities the Schools of Medicine are able to supply a complete curriculum. The students, however, must go elsewhere for degrees or diplomas.

UNIVERSITY COLLEGE, BRISTOL: FACULTY OF MEDICINE.—Extensive additions have been made to the Anatomical, Bacteriological, and Pathological Departments. Students of the College are admitted to the Clinical Practice of the Bristol Royal Infirmary and the Bristol General Hospital conjointly, and consequently both these institutions are open to all students, men and women alike. The Infirmary and the Hospital comprise between them a total of 470 beds; and both have very extensive out-patient departments, special departments for the Diseases of Women and Children, and of the Eye, Ear, and Throat, besides large out-door Maternity Departments and Dental Departments. Students may also attend the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of Medical and Surgical work. Each student has the opportunity of personally studying a large number of cases and of acquiring practical skill in diagnosis and treatment. The annual prize distribution will take place at the hand of Professor Francis Gotch, F.R.S., of Oxford, on Oct. 1st.

Courses of Lectures.—Medicine: Professor F. H. Edgeworth and Professor J. Michell Clarke. Surgery: Professor C. A. Morton and Professor James Swain. Anatomy: Professor Edward Fawcett. Practical Anatomy: Demonstrators, Dr. E. W. Hey Groves and Dr. W. S. Vernon Stock. Physiology and Histology: Professor A. F. Stanley Kent. *Demonstrator:* Dr. Fortescue-Brickdale. Chemistry: Professor Francis Francis. *Public Health:* Dr. D. S. Davies. Midwifery: Professor W. C. Swayne. Medical Jurisprudence: Dr. R. Eager and Dr. G. Parker. Pathology and Morbid Anatomy: Professor I. Walker Hall. Demonstrator: Dr. Carey F. Coombs. Operative Surgery: Mr. J. Paul Bush. Practical Medicine: Professor Edgeworth and Professor Michell Clarke. Practical Surgery: Dr. R. G. Poole Lansdown. Practical Midwifery: Mr. D. C. Rayner. Materia Medica and Practical *Pharmacy:* Mr. C. C. M. Davis. Pharmacology and *Therapeutics:* Dr. Newman Neild. Biology: Professor S. H. Reynolds. Practical *Chemistry:*

Skin Department: Dr. Graham Little. Dental Surgeon: Mr. W. H. Dolamore. Aural Surgeon: Dr. G. William Hill. Surgeon to the Throat Department: Dr. Scanes Spicer. Administrators of Anæsthetics: Mr. Henry Davis, Mr. Blumfeld, and Mr. Collum. Director in Medical Charge of Inoculation Department: Sir A. E. Wright. Dean: Mr. W. H. Clayton-Greene.

Lecturers.—Clinical Surgery: Mr. A. J. Pepper. Medicine: Dr. Sidney Phillips. Surgery: Mr. J. Ernest Lane and Mr. H. Stansfield Collier. Practical and Operative Surgery: Mr. V. W. Low and Mr. Maynard Smith. Pathology: Sir A. E. Wright and Dr. Spilsbury (assistant lecturer). Bacteriology: Sir A. E. Wright and Captain S. R. Douglas (assistant lecturer). Pathological Chemistry: Dr. W. H. Willcox. Midwifery and Gynæcology: Dr. M. Handfield-Jones. Materia Medica and Therapeutics: Dr. H. A. Caley. Forensic Medicine: Dr. A. P. Luff and Dr. Willcox. Descriptive and Surgical Anatomy: Mr. W. H. Clayton-Greene. Demonstrators: Mr. Maynard Smith and Mr. Fitzmaurice Kelly. Physiology and Histology: Dr. N. H. Alcock and Dr. B. J. Collingwood (assistant lecturer). Biology: Dr. W. G. Ridewood. Demonstrator: Mr. H. B. Fantham. Chemistry: Dr. G. Senter. Physics: Mr. W. H. White. Hygiene and Public Health: Dr. W. H. Willcox. Mental Diseases: Dr. Theo. B. Hyslop. Diseases of the Eye: Mr. Leslie Paton. Diseases of the Ear: Dr. G. William Hill. Diseases of the Skin: Dr. Graham Little. Diseases of the Throat: Dr. Scanes Spicer. Dental Surgery: Mr. Dolamore. Medical Tutor: Dr. W. J. Harris. Surgical Tutors: Mr. V. Warren Low, Mr. Clayton-Greene, and Mr. Maynard Smith. Obstetric Tutor: Dr. T. G. Stevens. Medical Registrar: Dr. F. S. Langmead. Surgical Registrar: Mr. C. I. Graham. Electrical Department: Dr. W. J. Harris. Practical Pharmacy: Mr. E. A. Andrews (demonstrator). School Secretary: Mr. B. E. Matthews.

MIDDLESEX HOSPITAL.—The hospital contains 345 beds, which includes a special wing for patients suffering from cancer, consisting of four wards, containing 45 beds; here cancer patients are received and attended for a period limited only by the duration of their disease. The number of patients treated last year were: Out-patients, 47,880; in-patients, 3859. Cancer: Out-patients, 87; in-patients, 159.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects included in the examinations in Medicine and Surgery in the United Kingdom and for the diploma in Public Health; and ample laboratory and class-room accommodation is provided for the teaching of the various subjects of the curriculum and for original research in Medicine, Pathology, or Bacteriology.

Special Classes are held to prepare students for the Inter. M.B. (Lond.) Examination and for the Primary and Final Examinations for the diploma of F.R.C.S. Eng.

Attached to the Cancer Wing of the hospital is a special research laboratory and in connexion with this there are the Emden Cancer Research Scholarship and the Richard Hollins Research Scholarship.

The Bacteriological and Public Health Laboratory for Women Medical Practitioners and Women Students, situated at 27, Mortimer-street, W., is in connexion with this hospital, and is under the direction of Mr. A. G. R. Foulerton, assisted by Dr. Hilda K. Whittingham. This laboratory, for the maintenance of which a private guarantee fund has been raised by some supporters of the hospital who are anxious to provide facilities for the special training of women in Public Health work, has been added to the Middlesex Hospital Medical School for the purposes of providing instruction for women medical practitioners for the examinations for the Diploma in Public Health and for the M.D. in State Medicine of the University of London, and of affording facilities to them and other women students for carrying out research work in Public Health, Bacteriology, and General Pathology.

Hospital Appointments.—All hospital appointments are allotted to students without any extra fee. The following 18 resident appointments—six house physicians, six house surgeons, two obstetric house physicians, two casualty medical officers, and two casualty surgical officers, are annually filled from the pupils of the hospital, each appointment extending over six months.

A Residential College to accommodate a limited number of students adjoins the hospital. Breakfast, luncheon, and dinner are supplied in the College Hall at moderate charges.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, the cricket club, the football clubs, the athletic clubs, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. The athletic ground, which is eight acres in extent, is situated within easy access at Wormwood Scrubs.

Fees.—The Composition Fee for the entire curriculum is 135 guineas, or 145 guineas if paid in three instalments. The fee for London University students is 145 guineas; for those who have passed the Preliminary Scientific 120 guineas. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students who have completed the study of Anatomy and Physiology or passed the London Preliminary Scientific M.B. Examination are received on special terms.

Lecturers.—Winter Session: *Anatomy: Dr. Wright.* Demonstrator: Dr. Gladstone. Biology and Physiology: Mr. Goodall. *Demonstrator*: Mr. Earle. *Chemistry*: Dr. Kellas. Medicine: Dr. Pasteur and Dr. Wynter. Practical Medicine: Dr. Voelcker. Emeritus Lecturer in Surgery: Mr. Henry Morris. Surgery: Mr. Clark, Mr. Pearce Gould, and Mr. Bland-Sutton. Practical Surgery: Mr. Murray. Operative Surgery: Mr. Murray. Practical Midwifery: Dr. Bonney. Pathology: Dr. Voelcker. Forensic Medicine and Toxicology: Dr. Wethered. Clinical Lectures in Medicine: The Physicians. Clinical Lectures in Surgery: The Surgeons. Clinical Lectures on Diseases of the Ear, Throat, and Nose: Mr. S. Paget. Lectures in Ophthalmology: Mr. Lang. Lectures in Dental Surgery: Mr. Hern. Public Health and Bacteriology: Mr. Foulerton. Summer Session: Pharmacology and Therapeutics: Dr. R. A. Young. Midwifery: Dr. Comyns Berkeley. Pathological Histology: Dr. Voelcker. Practical Toxicology: Dr. Kellas. Mental Diseases: Dr. Mickle. Lectures in Dermatology: Dr. Pringle. Anatomy, Chemistry, and Physiology: as in Winter Session. Tutors—Medicine: Dr. Campbell Thomson; Surgery: Mr. Kellock; Obstetrics: Dr. Victor Bonney.

Staff.—Consulting Physicians: Dr. W. Cayley, Dr. Sidney Coupland, and Sir Richard Douglas Powell. Physicians: Dr. J. K. Fowler, Dr. W. Pasteur, and Dr. W. E. Wynter. Obstetric Physician: Dr. W. Duncan. Physicians to Out-patients: Dr. A. F. Voelcker, Dr. F. J. Wethered, and Dr. H. Campbell Thompson. Assistant Physician: Dr. R. A. Young. Consulting Physician to the Skin Department: Dr. R. Liveing. Physician to the Skin Department: Dr. J. J. Pringle. Assistant Obstetric Physician: Dr. Comyns Berkeley. Consulting Surgeons: Mr. Nunn and Mr. Morris. Surgeons: Mr. Clark, Mr. Gould, and Mr. Bland-Sutton. Surgeons to Out-patients: Mr. Murray (Dean of the school) and Mr. Kellock. Assistant Surgeon: Mr. Handley. Ophthalmic Surgeon: Mr. W. Lang. Aural Surgeon: Mr. S. Paget. Dental Surgeon: Mr. W. Hern. Assistant Dental Surgeon: Mr. Nowell. Curator of the Museum and Pathologist: Dr. Lakin. Registrars: Dr. O. K. Williamson, Mr. Hastings, and Dr. Victor Bonney. Resident Medical Officer: Mr. Gordon Taylor. Anæsthetists: Mr. T. G. A. Burns and Mr. H. P. Noble. Assistant Anæsthetist: Mr. H. Charles.

ST. THOMAS'S HOSPITAL.—This hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 600 beds. The in-patients last year numbered 6608, whilst the number of attendances as out-patients, including the casualty and light departments, was 201,924. There are departments for the treatment of women, children, the eye, ear, nose and throat, skin, and teeth. Departments for light treatment, x rays, and physical exercises are also special features. Exceptional facilities are offered in the hospital laboratories for the study of general pathology, clinical pathology, and of treatment by serums and vaccines. Surgical operations take place in the main theatres every day at 1.30. Clinical teaching in the wards, out-patients' and special departments is available every day of the week. Clinical lectures are delivered every Wednesday and Thursday during the sessions. All appointments in the hospital are open to students without extra fee. House physicians, house surgeons, obstetric house physicians, ophthalmic house surgeons, and out-patient have every opportunity of acquiring a practical knowledge of their profession. Fees: £3 3*s.* a quarter, £10 10*s.* the first year, and £5 5*s.* subsequent years. A course of Practical Pharmacy is given by the dispenser. Fee £3 3*s.* for three months. Applications should be made to the Secretary of the Medical Committee.

Staff.—Consulting Physician: Dr. W. Millington. Consulting Surgeon. Physicians: Dr. H. Malet and Dr. C. A. MacMunn. Surgeons: Mr. J. O'B. Kough, Mr. W. H. T. Winter, Mr. E. Deanesly, and Mr. A. H. Hunt. Assistant Physician: Dr. J. A. Codd. Assistant Surgeons: Mr. W. F. Cholmeley and Mr. H. Dent.

NORFOLK AND NORWICH HOSPITAL (220 beds).—Non-resident pupils admitted. Fees: For three months, £3 3*s.*; for six months, £5 5*s.*; as permanent pupil, £8 8*s.* Consulting Physician: Sir P. Eade. Consulting Surgeons: Dr. Beverley, Mr. H. S. Robinson, and Mr. C. Williams. Physicians: Dr. Barton, Dr. Burton-Fanning, and Dr. Long. Surgeons: Mr. S. H. Burton, Mr. D. D. Day, and Mr. H. A. Ballance. Assistant Physician: Dr. A. J. Cleveland. Assistant Surgeons: Mr. T. H. Morse and Mr. E. W. Everett. Dental Surgeon: Mr. H. F. White. Electro-Therapeutist: Dr. A. J. Cleveland. Secretary: Mr. F. G. Hazell.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Dr. H. Davy and Dr. William Gordon. Surgeons: Mr. J. D. Harris, Mr. E. J. Domville, Mr. Charles E. Bell, and Mr. A. C. Roper. Medical Registrar and Pathologist: Mr. Reginald V. Solly. Surgeon Dentist: Mr. J. M. Ackland. Anæsthetists: Mr. Henry Andrew and Mr. Brennan Dyball. The hospital contains 200 beds (including special children's wards) and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery on application to the House Surgeon. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). An Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 200 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 2420; out-patients, 13,937. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians: Dr. H. Nicholls and Dr. S. King Alcock. Surgeons: Dr. G. Stokes Hatton and Dr. Wheelton Hind. Assistant Physicians: Mr. John Russell and Dr. W. E. L. Horner. Assistant Surgeons: Mr. Reginald Alcock and Dr. W. C. Allardice. Ophthalmic Surgeon: Mr. Herbert H. Folker. Assistant Ophthalmic Surgeon: Mr. R. H. Dickson. Medical Officer in Charge of the Electrical Department: Dr. G. H. List. Dental Surgeon: Mr. A. Baines. Secretary and House Governor: Mr. Albert E. Boyce, F.C.I.S., F.L.A.A.

SUSSEX COUNTY HOSPITAL (190 beds).—During the year 1906, 1988 in-patients have been treated. The total number of out-patient attendances on the books during 1906 was 33,668. This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

Staff.—Consulting Physicians: Dr. Rutter, Dr. Hollis, and Dr. Branfoot. Physicians: Dr. J. F. G. Dill, Dr. Hobhouse, and Dr. Maynard. Assistant Physicians: Dr. W. Broadbent, Dr. Hall, and Dr. Bailey. Consulting Surgeons: Mr. H. P. Blaker and Mr. W. Furner. Surgeons: Mr. T. J. Verrall, Mr. R. F. Jowers, and Mr. F. J. Paley. Assistant Surgeons: Mr. A. Buck, Mr. T. H. Ionides, and Mr. W. A. Bowring.

NORTHAMPTON GENERAL HOSPITAL (established 1743; rebuilt 1793).—Two new wings were opened in 1904 and the old buildings entirely renovated and re-arranged. The number of beds is 166. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10*s.* Pupils can be received at any time.

LEICESTER INFIRMARY.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 158 beds and at the Children's Hospital in connexion 42; total 200. There are about 3000 in-patients annually and 30,000 out-patients and casualties. A new wing containing 100 beds is now in course of construction and will be opened by H.R.H. the Duchess of Argyll on Nov. 5th next. A new Nurses' Home is also about to be erected.

Staff.—Three Honorary Physicians, four Honorary Surgeons, two Assistant Honorary Physicians, and two Assistant Honorary Surgeons. Special departments: Ophthalmic and Ear and Throat. House Governor and Secretary, Harry Johnson.

THE ROYAL HOSPITAL, PORTSMOUTH (founded 1847).—The number of beds is 132. During the year 1906 there were 1453 in-patients and 12,764 out-patients. Honorary Physicians: Dr. John Phillips and Dr. C. C. Claremont. Surgeons: Dr. J. Ward Cousins and Mr. Henry Randle, F.R.C.S. Honorary Anæsthetist: Dr. W. J. Essery. Honorary Assistant Physicians: Dr. W. P. McEldowney, Dr. J. T. Leon, and Dr. E. J Davis Taylor. Honorary Assistant Surgeons: Mr. C. P. Childe, F.R.C.S., Mr. T. A. M. Forde, Mr. A. B. Wright, and Mr. L. Cole Baker. The hospital is a preparatory School of Medicine and Surgery; the attendance of pupils at this hospital is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

KENT AND CANTERBURY GENERAL HOSPITAL.—The hospital contains 104 beds. Pupils of the staff are admitted to the practice of the hospital and have the use of the library of the East Kent and Canterbury Medical Society for £7 7*s.* Operation day, Thursday, 11 A.M. Physicians: Dr. Harold Wacher and Dr. M. T. Williams. Consulting Surgeons: Mr. James Reid and Mr. Frank Wacher. Surgeons: Dr. T. Whitehead Reid, Mr. J. Greasley, Mr. Sidney Wacher, and Mr. Z. Prentice. Dentist: Mr. R. S. N. Faro. Secretary: Mr. Arthur J. Lancaster. Over 700 in-patients, 2000 out-patients and casualties, and 400 dental cases are attended in a year.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Physician: Dr. William Gordon. Surgical Staff: Mr. A. C. Roper and Mr. Ransom Pickard. Assistant Surgeon: Mr. Leonard R. Tosswill. Secretary: Mr. Sidney E. Whitton. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1906, 2840.

SCOTLAND.

MEDICAL SCHOOLS WITH FULL CURRICULUM.[1]

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1200 students avail themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical

---

[1] For Scholarships see p. 633 et seq.

University College Hospital Medical School.—Dean: Professor Sidney Martin, M.D., F.R.C.P., F.R.S. Vice-Dean: H. Batty Shaw, M.D., F.R.C.P. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B S. Course, 80 guineas if paid in one sum, 82 guineas if paid in two instalments, as follows—first year, 50 guineas; second year, 32 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. Students who obtain a medical qualification within three years of the time of commencing this course are not required to pay an additional fee for further attendance. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham, and for the medical education required by the Examining Board in England and the Society of Apothecaries.

There are 279 beds in the hospital and 70,379 patients were treated last year.

Special Departments, Clinical or Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology are admitted to work in the laboratories of the school by the Professor. A special course of instruction is given for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies; also special courses of Lectures and Demonstrations in Anæsthetics, Diseases of the Eye, Ear, Nose, and Throat, Skin, and Diseases of the Teeth, in Electrical and Radioscopic Diagnosis and Treatment, and in Clinical and Tropical Pathology. These courses are designed for senior students and graduates.

Appointments tenable by Students.—Clerkships and dresserships to the physicians, surgeons, anæsthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Eight house physicians and house surgeons, four senior and four junior obstetric assistants are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: 1. The Resident Medical Officer. This officer is appointed for a period of two years and is chosen from amongst the more senior recent residents of the hospital. 2. The Surgical Registrar is also chosen from among the more senior recent residents of the hospital. 3. A Casualty Medical Officer and a Casualty Surgical Officer are appointed, each for a period of six months. 4. Deputy Anæsthetists. During the absence of one or another of the Anæsthetists in the summer months a senior qualified student is appointed as a substitute and is granted a special certificate.

School Buildings and Equipment.—The new buildings for University College Hospital, completed by the generosity of the late Sir Blundell Maple, Bart., were opened by H.R.H. the Duke of Connaught on Tuesday, Nov. 6th, 1906. The new buildings for the Medical School, erected through the generosity of Sir Donald Currie, are ready and contain accommodation for undergraduate and post-graduate students in all departments of medical study subsequent to the intermediate course.

Museum of Pathological Anatomy.—The Museum, a spacious and well-lighted room, is open for study from 8 A.M. to 5 P.M. The collection is divided into three sections—medical, surgical, obstetrical, and gynæcological. The surgical section is a particularly complete one and contains examples of every variety of surgical disease and injury. Diseases of the skin are well illustrated by a number of wax models which are conveniently displayed in glass cases. The obstetrical and gynæcological section is very complete. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston. It is also furnished with a small theatre, where separate demonstrations in each subject are given several times a week by members of the teaching staff.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 10,000 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College exists for the dual purpose (1) of promoting the study of Medical and Surgical Science, and (2) of promoting social intercourse among its members. All Students of the Medical School are eligible for membership. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine and the allied sciences and for the exhibition of cases of pathological interest. One room in the Medical School is specially reserved as a Reading Room and is provided with current medical works and periodicals. The society also possesses an osteological and a pathological collection for the use of its members. In its social aspect the society includes various athletic clubs and has the management of three rooms on the ground floor of the Medical School, which are supplied with newspapers, magazines, writing materials, chess- and draught-boards, &c., solely for the use of its members. The society also superintends the commodious gymnasium of the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the Great Western Railway station at Perivale and is within easy reach of the Hospital and School, about 25 minutes by train from Gower-street station. The following clubs are connected with the society: Cricket Club, Rugby Football Club, Association Football Club, Hockey Club, and Lawn-Tennis Club. The society also has the use of the College racquets and fives courts for its members. The affairs of the society are conducted by a committee elected annually by the members.

Residence of Students.—A register of boarding residences is kept in the office of the Medical School for the convenience of Students; these residences are not under the control of the school authorities. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge.

Private Instruction.—Gentlemen who desire assistance in their studies should consult the Dean, Professors, or Lecturers.

Hospital Staff.—Consulting Physicians: Sir W. R. Gowers, Dr. H. C. Bastian, Sir J. Williams, Bart., Dr. S. Ringer, and Dr. F. T. Roberts. Physicians: Sir Thomas Barlow, Bart., Dr. J. Rose Bradford, Dr. Sidney Martin, Dr. J. Risien Russell, and Dr. H. Batty Shaw. Assistant Physicians: Dr. F. J. Poynton and Dr. C. Bolton. Obstetric Physicians: Dr. H. R. Spencer and Dr. G. F. Blacker. Physician to Skin Department: Dr. H. Radcliffe Crocker. Consulting Surgeons: Sir John Tweedy (Ophthalmic) and Sir Victor Horsley. Surgeons: Mr. A. E. Barker, Mr. R. J. Godlee, Mr. Bilton Pollard, and Mr. Raymond Johnson. Assistant Surgeons: Mr. Rupert Bucknall and Mr. Wilfred Trotter. Ophthalmic Surgeon: Mr. Percy Flemming. Assistant Ophthalmic Surgeon: Mr. J. H. Parsons. Professor and Lecturer on Public Health: Dr. Henry R. Kenwood. Dental Surgeon: Mr. Sidney Spokes. Assistant Dental Surgeon: Mr. H. J. Relph. Anæsthetist: Dr. Dudley Buxton. Assistant Anæsthetists: Dr. H. J. Scharlieb and Mr. A. Beresford Kingsford. Surgical Registrar: Mr. O. L. Addison. Resident Medical Officer: Dr. A. M. H. Gray. Pathologist: Dr. F. H. Thiele. Electro-therapeutist: Mr. E. S. Worrall. Radiographer: Mr. R. H. Cooper. Pharmacist: Mr. R. R. Bennett.

Teaching Staff.—Medicine—The Principles and Practice of Medicine: Dr. J. Rose Bradford. Clinical Medicine: Sir Thomas Barlow, Dr. J Rose Bradford, Dr Sidney Martin, Dr. J. Risien Russell, Dr. H. Batty Shaw, Dr. F. J. Poynton, and Dr. C. Bolton. Therapeutics: Dr. H. Batty Shaw. Surgery—The Principles and Practice of Surgery: Mr. Arthur E. J. Barker. Clinical Surgery: Mr. Arthur E. J. Barker, Mr. Rickman J. Godlee, Mr. Bilton Pollard, Mr. Raymond Johnson, Mr. Rupert Bucknall, and Mr. Wilfred Trotter. Practical Surgery: Mr. Raymond Johnson and Mr. Wilfred Trotter. Surgical Anatomy: Mr. Wilfred Trotter. Midwifery and Gynæcology—Dr. H. R. Spencer. Clinical Midwifery and Gynæcology: Dr. H. R. Spencer and Dr.

Chemistry, Professor J. Robertson Watson; Physics, Professor Peter Bennett; Botany, Professor B. G. Cormack; Zoology, Professor Geo. Bell Todd; Physiology: Professor Robert Fullarton; Materia Medica, Professor John P. Duncan; Midwifery, Professor John Edgar; Surgery, Professor J. H. Nicoll; Practice of Medicine, Professor John Cowan; Ophthalmic Medicine and Surgery, Dr. T. Spence Meighan; Aural Surgery, Dr. J. Galbraith Connal; Diseases of Throat and Nose, Dr. John Macintyre; Public Health (Laboratory Course), Professor Carstairs C. Douglas. In summer: Anatomy, Practical Anatomy, and Osteology; Practical Chemistry; Botany and Practical Botany; Zoology and Practical Zoology; Practical Physiology; Practical Materia Medica and Pharmacy; Medical Jurisprudence and Hygiene (Professor Carstairs C. Douglas); Diseases of Women and Children (Professor Edgar); Operative Surgery; Ophthalmic Medicine and Surgery; Aural Surgery; Mental Diseases (Dr. John Carswell); and Public Health (Lecture Course). The Chemical Laboratory is open daily from 10 to 6. The Dissecting-room is open in winter from 9 A.M. to 6 P.M., and in summer from 6 A.M. to 6 P.M. The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted. The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them. The Dissecting-room is provided with a complete series of dissected specimens, mounted in plaster of Paris, illustrating the anatomy of the human body. Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of it, and four minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, and Operative Surgery. There are also provided a large reading-room and students' recreation-room.

Fees.—For each course of Lectures (Anatomy, Ophthalmic Medicine and Surgery, Aural Surgery, Diseases of Throat and Nose, and Mental Diseases and Public Health excepted), first session, £2 2*s.*; second session (in Anderson's College), £1 1*s.*; afterwards free. For Practical Classes (except Anatomy, Operative Surgery, and Public Health)—viz., Chemistry, Botany, Zoology, Physiology, and Pharmacy—first session, £2 2*s.*; second session, £2 2*s.* Reduced fees for Lectures with Laboratory Work in Botany or in Zoology during same summer session, £3 3*s.*; for Lecture Class or Practical Class separately, in Botany or in Zoology, £2 2*s.* Anatomy Class Fees: Winter, first session (including Practical Anatomy), £4 4*s.*; second session (including Practical Anatomy), £4 4*s.*; third session, £2 2*s.* Summer, Lectures and Practical Anatomy, £2 12*s.* 6*d.*; Lectures alone, £1 11*s.* 6*d.*; Practical Anatomy alone, £1 11*s.* 6d.; Osteology and Practical Anatomy, £2 12*s.* 6*d.*; Osteology alone, £1 11*s.* 6*d.*; Operative Surgery, £2 12*s.* 6*d.* Second Course, £2 2*s.* Joint fee for Classes of Systematic and Operative Surgery, £3 13*s.* 6*d.* Ophthalmic Medicine and Surgery (including Hospital Practice), Aural Surgery, Diseases of Throat and Nose, and Mental Diseases, £1 1*s.* each course. Public Health Laboratory, six months, £11 11*s.*; with lectures, £12 12*s.* Matriculation Fees: For the year, 10*s.*; for one class in winter session alone, 5*s.*; for summer session alone, 5*s.*

Western Infirmary.—Fees: For Hospital Attendance, £10 10*s.*; afterwards free. For Clinical Instruction, winter, £3 3*s.*; summer, £2 2s. Pathology: systematic, £4 4*s.*; practical, £3 3*s.* Vaccination fee, £1 1*s.*

Royal Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s.*; second year, £10 10*s.*; afterwards free. Six months, £6 6*s.*; three months, £4 4*s.* Pathology, both courses, £4 4*s.* Vaccination Fee, £1 1s.

Attendance at the dispensaries of the Western and Royal Infirmaries is included in the hospital fee.

Maternity Hospital.—Fee for six months, £3 3*s.*

Royal Hospital for Sick Children.—Fee for one year, £1 1*s.*

Eye Infirmary.—Fee: Hospital Practice and Clinical instruction, including Lectures at the College, six months, £1 1*s.*

Lock Hospital.—£1 1*s.*

Fever Hospital, Belvidere or Ruchill.—Fee, £1 1*s.*

Hospital for Skin Diseases.—Fee, £1 1*s.*

The Carnegie Trust extends its benefactions to students at Anderson's College Medical School. Full particulars may be obtained from Mr. W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions); by the Royal Colleges of Physicians of London and Edinburgh; by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland; by the Royal College of Physicians of Ireland; by the Faculty of Physicians and Surgeons of Glasgow; by the Society of Apothecaries, London; and by the Army, Navy, and East India Boards. The courses of Laboratory Instruction and Lectures in Public Health are recognised by the Scottish Colleges; by the Royal College of Physicians and the Royal College of Surgeons, Ireland; and by the University of Cambridge. Communications relating to the Medical School to be addressed to the Secretary of the Medical Faculty, Anderson's College Medical School, Dumbarton-road, Partick, Glasgow. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Alexander Mackay, Educational Institute Office, 40, Princes-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Alexander Duncan, LL.D., Faculty Hall, 242, St. Vincent-street, Glasgow. Communications relating to the Dental School to be addressed to Mr. D. M. Alexander, 97, West Regent-street, Glasgow.

The Kerr Bursary in Anatomy (value about £10) is open to students of the Junior Anatomy Class during Winter Session 1907–1908.

The Winter Session will be opened on Thursday, Oct. 17th, 1907, and will be closed on Thursday, March 26th, 1908.

The Summer Session will be opened on Wednesday, April 22nd, 1908, and will be closed on Friday, July 3rd, 1908.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This College was incorporated in 1889. The Glasgow Royal Infirmary was founded in 1791. The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary. The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements. Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories. A complete electric light installation has been added and a powerful Educational Lantern has been provided for demonstration purposes. The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest hospitals in the kingdom. The winter session will open on Thursday, Oct. 17th.

Psychological Medicine.—Practical instruction is given in Woodilee Asylum, situated within a short distance of Glasgow and having accommodation for 850 patients. Six resident clinical clerks are appointed annually. These clerkships are open to students attending St. Mungo's College.

Clinical Instruction in Fevers.—Classes are conducted by Dr. Johnston, Superintendent, at the City of Glasgow Fever Hospital, Ruchill, and Dr. Brownlee, Superintendent, at the City of Glasgow Fever Hospital, Belvidere.

Clinical Instruction in Midwifery.—The close proximity of the Maternity Hospital enables the Professor of Midwifery to conduct frequent clinical demonstrations there during the summer session.

The classes in St. Mungo's College qualify for the English, Scotch, and Irish Conjoint Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College.

which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, with accommodation for 17 students, and the Secretary can be consulted on the subject of other residences for students. There is a Tennis Club with a gravel court at the School, and also hockey, boating, and other clubs.

Staff.—Consulting Physicians: Dr. S. West and Dr. T. Crawfurd Hayes. Physicians: Dr. Harrington Sainsbury, Dr. J. W. Carr, and Dr. R. H. P. Crawfurd. Assistant Physicians: Dr. A. G. Phear and Dr. Farquhar Buzzard. Consulting Surgeons: Mr. W. Rose and Mr. A. B. Barrow. Surgeons: Mr. J. Berry, Mr. E. W. Roughton, and Mr. W. H. Evans. Assistant Surgeons: Mr. T. Percy Legg and Mr. Cunning. Physician for Diseases of Women: Mrs. Scharlieb, M.S., M.D. Assistant Physician for the Diseases of Women: Miss Vaughan, M.D. Ophthalmic Surgeon: Mr. H. Work Dodd. Surgeon for Diseases of Throat, Nose, and Ear: Mr. E. W. Roughton. Surgeon for Diseases of Skin: Mr. W. H. Evans. Senior Resident Medical Officer: Mr. Atkey. Registrars: Miss Roberts, M.D., B.S., and Miss Turnbull, M.D., B.S. Dentist: Mr. T. C. Budden. Anæsthetists: Mrs. Berry, M.D., B S., and Mrs. Willey, M.S., M.D. Secretary: Mr. C. W. Thies.

Lecturers.—At the School: Anatomy and Practical Anatomy: Mr. Parsons. Physiology and Practical Physiology: Dr. Brodie and Miss Cullis. Chemistry: Miss C. de B. Evans, D.Sc. Practical Chemistry: Miss Widdows, B.Sc. Physics: Miss E. Stoney. Biology: Mr. Mudge. Materia Medica: Dr. R. H. P. Crawfurd. Practice of Medicine: Miss Cock, M.D., and Dr. J. W. Carr. Midwifery: Mrs. Scharlieb, M.S. *Gynæcology*: Mrs. Stanley Boyd. Forensic Medicine: Dr. Hawthorne. Toxicology: Dr. Wilson Hake. Practice of Surgery: Mr. Berry and Mr. Roughton. Operative Surgery: Mr. Roughton. Ophthalmic Surgery: Miss Ellaby. Pathology: Dr. F. W. Andrewes. Mental Pathology: Dr. Hyslop. Tropical Diseases: Sir Patrick Manson. Operative Midwifery: Miss McCall, M.D., and Miss Vaughan, M.D. Demonstrator of Practical Gynæcology, Miss Vaughan, M.D.; of Anatomy, Miss Hamilton, M.D., and Miss Bolton, M.B., B.S.; of Chemistry, Miss Laycock, B.Sc.; of Practical Pharmacology, Mrs. Clarke Keer. At the Royal Free Hospital: Clinical Medicine: Dr. Sainsbury and Dr. Carr. Clinical Surgery: Mr. Berry and Mr. Roughton. Clinical Obstetrics: Mrs. Scharlieb, M.S. Pathology: Dr. Phear. Bacteriology: Mr. Roughton. Surgical Tutors: Mr. W. Evans, Mr. Legg, and Mr. Cunning. Medical Tutor: Dr. Crawfurd. Demonstrator of Auscultation: Dr. Phear. Demonstrator of Practical Clinical Pathology: Miss Chambers, M.B., B.S. Practical Pathology: Miss Woodward, M.B., B.S.

Dean of the School, Miss Cock, M.D.; Honorary Secretary, Mrs. Thorne; Secretary, Miss Douie, M.B.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

THE institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses two hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds. It has also two Dispensaries—one in the East India Dock-road and the other at Gravesend—from which the patients are transferred to the hospitals. The London School of Tropical Medicine and the London School of Clinical Medicine are both under the auspices of the Seamen's Hospital Society. The medical staff administering the hospitals of the Seamen's Hospital Society is as follows:—Physicians: Sir Dyce Duckworth, Dr. F. Taylor, Dr. J. Rose Bradford, Sir Patrick Manson, K.C.M.G., Professor B. Tanner Hewlett, Dr. Guthrie Rankin, and Dr. Andrew Duncan. Surgeons: Sir William Bennett, K.C.V.O., Mr. A. Carless, Mr. W. Turner, Mr. J. Cantlie, Mr. L. H. McGavin, and Mr. A. Evans. Ophthalmic Surgeon: Mr. L. V. Cargill. Physician for Diseases of the Skin: Mr. Malcolm Morris. Physician for Diseases of the Throat, Nose, and Ear: Dr. StClair Thomson. Dental Surgeon: Mr. K. W. Goadby. Assistant Physicians: Dr. S. R. Wells, Dr. A. E. Jones, Dr. F. M. Sandwith, Dr. C. W. Daniels, and Dr. R. E. Bickerton. Assistant Surgeons: Mr. L. A. Jones, Mr. E. Rock Carling, and Dr. O. C. Choyce. Assistant Physician for Diseases of the Skin: Dr. W. Fox. Assistant Surgeon for Diseases of the Throat, Nose, and Ear: Mr. A. Lawrence Anæsthetists: Dr. M. Horne, Dr. C. Hughes, Dr. V. B. Orr, Mr. T. G. Scott, and Dr. R. E. Delbruck. Medical Superintendent of *Dreadnought* Hospital: Dr. C. C. Choyce. Medical Officer East India Dock-road Dispensary: W. H. F. Oxley. Surgeon Gravesend Dispensary: C. E. Robbs. Secretary: P. J. Michelli.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 160 beds, all of which are at present in use. About 2600 in-patients and 37,000 out-patients, whose attendances number 100,000, are treated annually. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms daily and demonstrations are given in the wards on certain fixed days. Post-graduate lectures and demonstrations are given daily except Saturdays; notice of the commencement of each course is advertised in the medical journals. Special Classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynæcology, Medical Electricity, Operative Surgery, Bacteriology, Anæsthetics, Intestinal Surgery, Surface Anatomy, Blood and Urine, Clinical Microscopy, Tropical Medicine, Cystoscopy, Venereal Diseases, and Operative Ophthalmology. The accommodation for post-graduates consists of a large lecture room, together with reading and writing rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology, a class being held every month. The fees for hospital practice, including lectures, are £5 5*s.* for three months or £12 12*s.* for one year. The certificate of the hospital is accepted by the Admiralty, War Office, and India Office in cases of study leave. Further information can be obtained on application to the Dean, Mr. L. A. Bidwell, at the hospital. Physicians: Dr. D. W. G. Hood, C.V.O., Dr. Seymour Taylor, and Dr. A. P. Beddard. Physician for Diseases of Women: Dr. J. A. Mansell-Moullin. Surgeons: Mr. C. B. Keetley, Mr. F. Swinford Edwards, Mr. S. Paget, and Mr. L. A. Bidwell. Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Assistant Surgeon for Diseases of the Eye: Dr. Kenneth Scott. Assistant Physicians: Dr. E. A. Saunders, Dr. H. Davis, and Dr. A. E. Russell. Assistant Physician for Diseases of Women: Dr. G. H. Drummond Robinson. Assistant Surgeons: Mr. A. Baldwin, Mr. Donald Armour, and Mr. John Pardoe. Surgeon-Dentist: Mr. H. Lloyd Williams. Physician in charge of Throat and Nose and Aural Department: Dr. J. B. Ball. Assistant Physician Aural Department: Dr. H. J. Davis. Physician in charge of Children's Department: Dr. E. A. Saunders. Surgeon in charge of Orthopædic Department: Mr. C. B. Keetley. Pathologist: Dr. G. C. Low. Dermatologist: Dr. P. S. Abraham. Officer in charge of the X Ray Department: Dr. D. Arthur. Administrators of Anæsthetics: Messrs. T. Gunton Alderton, Rickard W. Lloyd, E. W. Lewis, and G. P. Shuter. Assistant Anæsthetists: Messrs. Austin Cooper, E. F. Travers, and Dr. H. M. Page. Electrician: Mr. E. D. MacDougal. Secretary of the Hospital: Mr. R. J. Gilbert; of the Post-Graduate College: Mr. H. Grant Rawle.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the Honorary Staff there are two resident House Physicians, three resident House Surgeons, five Anæsthetists, Registrar, Pathologist, and Casualty Officer. The hospital contains 162 beds which are now fully occupied. The large rectangular and circular wards, each of which contains 24 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. An electrical department is being arranged. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patient departments and during the coming winter session there will be a weekly clinical lecture. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their

Branch, about 986 beds. Medical Superintendent: Dr. William Reid. *Assistant Physicians:* Dr. T. C. Mackenzie, Dr. Reg. A. Forster, and Dr. John H. Moir. *Clerk, Treasurer, and Factor:* Mr. A. Scott Finnie, 343, Union-street, Aberdeen. *Clinical instruction is given to* students during three months in summer.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ROYAL INFIRMARY, Edinburgh.—*This hospital has over 900* beds and 60 cots for children, the average daily number of patients for *1906 being 839. Beds* are set apart for clinical instruction by *the* professors of the University of Edinburgh. Courses of *Clinical Medicine* and Surgery are also given by the *ordinary* physicians and surgeons. Special instruction is given on Diseases of Women, Physical Diagnosis, *Diseases of the Skin,* Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, *Diseases* of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also *to cases* of Incidental *Delirium or Insanity.* There are also large and *complete* Medical Electrical and X Ray and Bathing Departments. *Three wards are* specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are *conducted* in the *anatomical* theatre by the *pathologist* and his *assistants,* who also give practical instruction in Pathological Anatomy *and Histology.* The fees for hospital *attendance* are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6*s.*; six *months,* £4 4*s.*; *three months,* £2 2*s.*; monthly, £1 1*s.* Separate payments amounting to £12 12*s.* entitle the student *to a* life ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. *Resident* physicians and surgeons are appointed and live in the house free of charge. The appointment is *for six months but may be* renewed at the end of that period by special recommendation. 2. Non-resident house *physicians and surgeons* and clinical assistants are appointed for six months. *The* appointment may be renewed for a like period *by special* recommendation. 3. Clerks and *dressers are* appointed by the physicians and surgeons. These appointments are open to all students and junior *practitioners holding* hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

Staff: Medical Department.—Consulting Physicians: Dr. Claud Muirhead, Dr. J. O. Affleck, and Dr. Andrew Smart. Consulting Gynæcologists: Sir J. Halliday Croom and Emeritus Professor Sir A. R Simpson. Professors of Clinical Medicine: Sir *T. R. Fraser,* Dr. W. S. Greenfield, and Dr. John Wyllie. Ordinary Physicians and Lecturers on Clinical Medicine: Dr. Byrom Bramwell, Dr. Geo. Gibson, Dr. Alex. Bruce, Dr. R. W. Philip, and Dr. W. Russell. Gynæcologists: Dr. A. H. F. Barbour and Mr. N. T. *Brewis.* Physician for Disease of the Skin: Dr. Norman Walker. Medical Electrician: Dr. Dawson Turner. *Assistant Physicians:* Dr. Murdoch Brown, Dr. G. Lovell Gulland, Dr. J. J. Graham Brown, Dr. Francis D. *Boyd, Dr.* R. A. Fleming, Dr. Harry Rainy, and Dr. Chalmers Watson. Assistant Gynæcologists: Dr. *F. W. N. Haultain, Dr. J.* Haig Ferguson, and Dr. Wm. Fordyce. Assistant Physicians for Diseases of the Skin: Dr. Fred. Gardiner and Dr. R. Cranston Low. Assistant Medical Electrician: Dr. Hope *Fowler.* Medical Registrar: Dr. A. Dingwall Fordyce.

Surgical Department.—Consulting *Surgeons:* Sir P. H. Watson, Mr. Joseph Bell, Mr. A. G. Miller, and Dr. P. H. Maclaren. Consulting Ophthalmic *Surgeons:* Dr. Argyll Robertson and Mr. *George A.* Berry. *Consulting* Aural Surgeons: Dr. P. McBride and Dr. McKenzie Johnston. Consulting Dental Surgeon: Dr. John Smith. Regius Professor of Clinical Surgery: Mr. Annandale. Professor of Surgery: Mr. Chiene. Ordinary *Surgeons:* Mr. J. M. Cotterill, Mr. C. W. Cathcart, Mr. F. M. Caird, and Mr. J. W. B. Hodsdon. Ophthalmic *Surgeons:* Dr. George Mackay and Dr. Wm. G. Sym. Surgeons to Ear and Throat Department: Dr. A. Logan Turner and Dr. J. Malcolm Farquharson. Dental Surgeons: Mr. William Guy and Mr. J. H. Gibbs. Assistant Surgeons: Mr. D. Wallace, Mr. Alexis *Thomson,* Mr. Alexander Miles, Mr. J. W. Dowden, Mr. A. A. Scot Skirving, Mr. Geo. L. Chiene, and Mr. W. Stuart. Assistant Ophthalmic Surgeons: Dr. J. V. Paterson and Dr. A. H. H. Sinclair. Assistant Surgeons to the Ear and Throat Department: Dr. John S. Fraser and Dr. John D. Lithgow. Pathologist: Dr. Theodore Shennan. *Assistant Pathologists: Dr. W. T. Ritchie (Clinical Pathology),* and Dr. Henry Wade and Dr. Carnegie Dickson (Morbid *Anatomy). Surgical Registrar: Dr.* Scott Carmichael. Superintendent: Colonel W. P. Warburton, I.M.S. (retired), M.D., C.S.I.

ROYAL INFIRMARY, GLASGOW.—This infirmary, which is the *largest in Glasgow,* is *situated* in Cathedral-square, Castle-street, and has car communication with every part of *the city.* St. *Mungo's College* is in the infirmary grounds.[1] The infirmary has, including the Ophthalmic *Department, over 620 beds, the* average number occupied in 1905 being 600. When the reconstruction of the infirmary, which was begun *two* years ago, is completed it will have about 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. Wards are set apart for the teaching of Women Students. At the Out-door Department the attendances in 1906 numbered over 135 000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and nine house surgeons, having a legal qualification in medicine and surgery, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and *surgeons. As* a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. A fully equipped Electrical Pavilion was opened a few years ago and year by year the latest and most approved apparatus for diagnosis *and treatment has* been added. The fees for hospital attendance, including clinical lectures and tutorial instruction, *attendance* at the out-door department, at the pathological department, post-mortem examinations, and the use of the museum, which has recently been re arranged and catalogued, are as follows: For *one year,* £10 10*s.*; for six months, £6 6*s.*; for three *months,* £4 4*s.* Students who have paid fees to the amount of £21 to the Glasgow Royal Infirmary shall be permitted to attend in any subsequent year or years one winter and one summer course of instruction in the infirmary without further payment; and students who have paid to any other hospital in the United Kingdom fees, being not less than £21, in virtue of which they are entitled to attend without further payment, shall be admitted as students of the Royal Infirmary on payment of £3 3*s.* for six months or £1 11*s.* 6*d.* for three months.

Staff.—Visiting Physicians: Dr. D. S. Middleton, Dr. T. K. Monro, Dr. W. K. Hunter, Dr. J. M. Cowan, and Dr. J. B. Mackenzie Anderson. Visiting Surgeons: Mr. John Barlow, Mr J. A. Adams, Mr. David Newman, Mr. Q. McLennan, Mr. J. H Pringle, Mr. H. Rutherfurd, and Mr. P. Paterson Consulting Surgeon for Diseases of the Eye: Dr. A. Maitland Ramsay. Surgeon for Diseases of the Throat and Nose and Consulting Medical Electrician: Mr. J. Macintyre. Gynæcologist: Dr. J. K. Kelly. Surgeon for Diseases of the Ear: Mr. J Kerr Love. Pathologist and Curator of Museum: Dr. Charles Workman. Assistant Pathologist: Dr. Mary Baird Hannay. Bacteriologist: Mr. David McCrorie. Assistant Bacteriologists: Mr. J. A. Campbell and Dr. Lizzie T. Fraser. *Medical Electrician:* Mr. J. R. Riddell. Assistant Medical Electricians: Dr. Samuel *Capie, Katharine* M. Chapman, L R.C.P. *Edin.,* and Dr. Janie S. McLauchlan Anæsthetist: Dr. King *Patrick.* Vaccinator: *Dr.* H. H. Borland. *Dispensary* Physicians: Mr. David McCrorie, Dr. John Henderson, *Dr. Campbell* S. Marshall, Dr. James Scott, Dr. J. T. McLachlan, *and* Dr. A. W. Harrington. Extra Dispensary *Physicians:* Dr. Archibald Jubb and Dr. Dugald McPhail. *Dispensary* Surgeons: Mr. A. N. McGregor, Mr. John *Patrick,* Mr. John A. C. Macewen, Mr. A. C. Faulds, Mr. *Thomas Kay,* and Mr. Robert Ramsey. Extra *Dispensary* Surgeons: Mr. James Battersby, Mr. Donald Duff, and Mr. W. H. Steel. Dispensary Specialists:—Diseases of Women: Dr. Balfour Marshall, Dr. Peter McBryde, *Dr. W. D.* Macfarlane, and Dr. Agnes W. Cameron; Diseases of the Ear: Mr. J. Kerr Love and Dr. James *Adam;* Diseases of the Skin: Dr. Alexander Morton and Dr. G. McIntyre; Diseases of the Throat and *Nose: Dr.* R. Fullerton and Dr. Grant; *Diseases* of the Eye: Dr. J. Rowan and Dr. H. W. Thomson; Diseases

[1] See section "Medical Schools with Full *Curriculum.*"

Sargent. Ophthalmic Surgeon: Mr. Marcus Gunn. Assistant Ophthalmic Surgeon: Mr. Leslie Paton. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Sir Felix Semon. Gynæcologist: Dr. Walter Tate. Anæsthetist: Dr. Llewelyn Powell. Director, Research Department: Dr. Gordon Holmes. Assistant Pathologist: Dr. J. Grainger Stewart. Registrar: Dr. C. M. H. Howell. House Physicians: Dr. S. A. K. Wilson, Dr. R. F. Kennedy and Dr. H. R. Prentice. The hospital is a school of the University of London and has been recognised by the Conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, and hospital practice should be addressed to the Secretary at the hospital.

BETHLEM ROYAL HOSPITAL.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, commencing July 1st and Jan. 1st, and will be provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. They will be under the direction of the Resident Physician and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners may attend for a period of three months on payment of a fee of £3 3*s*. Lectures are also given in connexion with the London Post-graduate Course.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton (318 beds).—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1*s*. for one month; three months, £2 2*s*.; perpetual, £5 5*s*. Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The next course will commence in October. Clinical Assistants are appointed to the Assistant Physician in the out-patient department and Clinical Clerks to the Physician in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 318 beds in the two buildings. Consulting Physicians: Dr. J. E. Pollock, Sir Richard Douglas Powell, Dr. F. T. Roberts, Dr. C. T. Williams, Dr. J. M. Bruce, Dr. T. H. Green, Dr. J. K. Fowler, Dr. T. D. Acland, and Dr. P. Kidd. Physicians: Dr. R. Maguire, Dr. H. W. G. Mackenzie, Dr. S. H. Habershon, Dr. F. J. Wethered, Dr. P. Horton-Smith Hartley, and Dr. J. J. Perkins. Assistant Physicians: Dr. A. Latham, Dr. H. Batty Shaw, Dr. W. C. Bosanquet, Dr. R. A. Young, Dr. C. Wall, and Dr. W. J. Fenton. Consulting Surgeons: Lord Lister and Mr. R. J. Godlee. Surgeon: Mr. S. Boyd. Dental Surgeon: Mr. G. L. Bates. Resident Medical Officer: Dr. F. C. Shrubsall.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—During the past year 1256 in-patients have been treated in the wards, and the large number of 38,290 cases since the opening of the wards in 1855. The number of out-patients treated during 1905 was 16,688 and 722,074 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to the Secretary of the Clinical Sub-committee at the hospital. Consulting Physicians: Dr. J. C. Thorowgood, Dr. Eustace Smith, Dr. Vincent D. Harris, Sir William S. Church, Dr. E. Clifford Beale, and Dr. Harrington Sainsbury. Consulting Surgeon: Lord Lister. Physicians: Dr. G. A. Heron, Dr. T. Glover Lyon, Sir Hugh Beevor, Bart., Dr. W. J. Hadley, Dr. E. H. Colbeck, and Dr. Arnold Chaplin. Surgeon: Mr. G. Lenthal Cheatle. Physicians to Out-patients: Dr. Hugh Walsham, Dr. Oliver K. Williamson, Dr. Clive Riviere, Dr. O. F. F. Grünbaum, Dr. A. I. Simey, and Dr. T. Lewis. Surgeon Dentist: Mr. Evelyn C. Sprawson. Secretary: Henry T. Dudley Ryder. Secretary of the Medical Committee: Dr. O. F. F. Grünbaum.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (80 beds.)—This hospital provides accommodation for 80 in-patients. Expenditure for 1906 £6175; income (including legacies, £733), £5725. The attendance of out-patients averages 27,000 annually. Consulting Physicians: Dr. Horace Dobell, Dr. P. J. Hensley, and Professor D. W. Finlay. Physicians: Dr. W. H. White, Dr. Oswald Browne, Dr. A. Davies, Dr. J. Calvert, Dr. M. Leslie, and Dr. J. H. Drysdale. Assistant Physicians: Dr. A. G. Phear, Dr. H. E. Symes Thompson, and Dr. J. Graham Forbes. Consulting Surgeons: Mr. J. Hutchinson and Mr. Pearce Gould. Surgeon: Mr. W. Turner. Resident Medical Officer: Dr. A. S. Hosford. House Physician: Dr. Campbell Anderson. Secretary: Mr. A. T. Mays.

THE MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, HAMPSTEAD AND NORTHWOOD, CENTRAL OUT-PATIENT DEPARTMENT, Fitzroy-square, W.—The Hospitals contain 220 beds. Number of in-patients, 1291; out-patients, 5800. Resident Medical Staff. Lectures and Clinical Demonstrations are given by the Visiting Medical Staff at the Hospital at Hampstead and the Out-patient department. The next course begins in October, at the out-patient department. Clinical assistants are appointed to physicians in the wards, and in the out-patient department. Consulting Physicians: Sir Hermann Weber and Dr. T. Clifford Allbutt. Consulting Surgeon: Mr. W. Watson Cheyne, C.B. Physicians: Dr. J. Edward Squire, C.B., Dr. F. W. Tunnicliffe, Dr. George Johnston, Dr. F. Parkes Weber, Dr. T. N. Kelynack, and Dr. T. D. Lister. Assistant Physicians: Dr. F. W. Price and Dr. A. J. Whiting. Pathologist: Dr. F. W. Price. Surgeon: Mr. James Berry. Laryngologist: Mr. Harold Barwell. Anæsthetist: Dr. Herbert Scharlieb, C.M.G., Dental Surgeon: Mr. F. Lawson Dodd.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—This hospital, which has been recently again enlarged and in which many important improvements have been carried out, receives over 1700 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. Fees: Medical Students, £8 8*s*. for four weeks; Qualified Medical Practitioners, £8 8*s*. for four weeks. Pupil Midwives (including board and lodging), £35 for five months; Pupil Nurses (including board and lodging), £24 for sixteen weeks. The new residence for students and qualified practitioners is opposite the hospital, with which it is in telephonic communication. Terms for residence and full board 35*s*. per week. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital. Students join preferably on the first Monday in each month. Consulting Physicians: Dr. George B. Brodie and Dr. W. S. A. Griffith. Consulting Surgeon: Mr. Alfred Willett. Physicians to In-patients: Dr. W. Rivers Pollock, Dr. W. J. Gow, Dr. T. W. Eden and Dr. A. F. Stabb. Physicians to Out-patients: Dr. C. Hubert Roberts, and Dr. H. Williamson.

THE HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with the out-patient department there has been for some years a well-organised Clinical Department. Gentlemen are appointed to act as clinical assistants to the gynæcologists to out-patients. The appointments are open to qualified medical men. They are entitled to receive notice of all operations performed within the hospital, and every facility is afforded them by the gynæcologists in the out-patient department of obtaining experience in diagnosis and treatment and the practical use of instruments Fee for one month £3 3*s*.; for each subsequent month £2 12*s*. 6*d*. The hospital contains 60 beds. In the out-patient department there were over 4000 new cases during the past year, the total number of out-patient attendances being 16.338. This large number affords exceptional opportunities for examining and studying most of the varieties of the diseases of women. Applications should be made to the Dean. Consulting Physicians: Dr. C. H. Carter and Dr. E. Holland. Consulting Surgeon: Mr. H. A. Reeves. Consulting Surgeon Dentist: Mr. Canton. Gynæcologists: Dr. Richard Smith, Dr. J. A. Mansell-Moullin, Dr. Bedford Fenwick (in charge of out-patients), Dr. James Oliver, Dr. J. H. Dauber, and Dr. A. E. Stevens. Assistant Gynæcologist: Dr. H. J. F. Simson. Surgeon: Mr. D. Drew. Assistant of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the surgeon whose clinique they are attending when he visits his patients. They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation. Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Joint Secretaries and acting Treasurers: William George Black and Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October.

IRISH SCHOOLS OF MEDICINE.[1]

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. A refreshment-room is now open where students can have luncheon. There are special rooms set apart for lady students. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences Oct. 1st; Summer Session, April 1st. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green, W., Dublin.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each. Two are tenable by matriculated students of the first, second, third, fourth, and fifth years of their course respectively. The examinations for Scholarships take place at the commencement of the session. A Travelling Medical Scholarship, value £100, will be awarded in the spring of 1909. Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c., of the Royal University of Ireland are also open to students. Lectures in Medicine at Queen's College, Belfast, will commence on Oct. 15th and end on March 31st. The Summer Medical Classes will begin on May 4th, except Botany, which begins on March 30th. The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes, balance room, &c., provided with all modern appliances. Special facilities are given to those who wish to pursue original research. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's, and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The medical museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The pharmaceutical laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines. Clinical instruction is given at the Royal Victoria Hospital, the medical staff of which is as follows:—Physicians: Professor Sir William Whitla, Professor James A. Lindsay, Dr. William Calwell, and Dr. H. L. McKisack. Surgeons: Mr. J. Walton Browne, Professor T. Sinclair, Mr. A. B. Mitchell, and Mr. T. S. Kirk. Gynæcologist: Professor Sir John Byers. Surgeon for Diseases of the Eye, Ear, and Throat: Mr. James A. Craig. Pathologist: Professor W. St.C. Symmers. Physician for Diseases of the Skin: Dr. W. Calwell. Assistant Physicians: Dr. W. B. McQuitty and Dr. J. S. Morrow. Assistant Surgeons: Mr. Robert Campbell and Mr. Andrew Fullerton. Assistant to the Gynæcologist: Mr. R. J. Johnstone. Assistant Surgeon Eye, Ear, and Throat Department: Mr. Henry Hanna. Assistant to the Pathologist: Dr. David Kirkhope. Administrators of Anæsthetics: Dr. V. G. L. Fielden, Dr. M. B. Smith, and Dr. F. C. Smyth. Medical Electrician: Dr. J. C. Rankin. Hæmatologist: Dr. Thomas Houston. Medical Tutor: Dr. S. H. G. Blakely. Surgical Tutor: Mr. Howard Stevenson. Registrars: Dr. J. E. MacIlwaine and Dr. S. T. Irwin. The Belfast Union and Fever Hospitals, the Ulster Hospital for Diseases of Women and Children, the Maternity Hospital, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Hospital for Sick Children, and the District Lunatic Asylum are open to students. Full information can be had from the Registrar, Queen's College, Belfast.

Professors and Lecturers—Natural Philosophy: W. Blair Morton, M.A. Chemistry: E. A. Letts, D.Sc., F.R.S.E. Natural History: Gregg Wilson, D.Sc. Anatomy: Johnson Symington, M.D., F.R.S. Physiology (Dunville): T. Hugh Millroy, M.D. Medicine: J. A. Lindsay, M.D., F.R.C.P. Surgery: T. Sinclair, F.R.C.S. Midwifery: Sir John W. Byers, M.D. Pathology (Musgrave): W. St.C. Symmers, M.B. Materia Medica: Sir William Whitla, M.D. Medical Jurisprudence: W. St.C. Symmers, M.B., and T. Houston, M.D. Ophthalmology: C. E. Shaw, M.D. Sanitary Science: E. A. Letts, D.Sc., and W. J. Wilson, M.B. Vaccination: J. McLiesh, M.B., D.P.H.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course.

Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are open to students in their first four years and the Blayney Scholarship, value £32, and a Senior Exhibition to students in their fifth year.

Students can attend the North and South Infirmaries, the Cork Union Hospital, the Cork Fever Hospital, the County and City of Cork Lying-in Hospital, the Cork Maternity, the County and City of Cork Hospital for Diseases of Women and Children, the Cork Eye, Ear, and Throat Hospital, and the Cork District Lunatic Asylum.

Staff, North Infirmary.—Physicians: Dr. D. D. Donovan and Dr. E. Magner. Surgeons: Dr. Cotter, Dr. C. Y. Pearson, Dr. N. J. Hobart, and Dr. D. J. O'Mahony. Assistant Physician: Dr. R. B. Dalton. Assistant Surgeons: Dr. J. Dundon and Dr. R. P. Byrne. Pathologist: Dr. Denis Murphy. House Physician: Dr. D. F. Hegarty. House Surgeon: Dr. D. M. Donovan. Surgeon Dentist: Mr. W. Pericho.

Staff, South Charitable Infirmary.—Physicians: Dr. P. T. O'Sullivan and Dr. N. I. Townsend. Surgeons: Dr.

---

[1] For Scholarships see p. 640 et seq.

Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary. Consulting Physician: Sir Stephen Mackenzie. Consulting Surgeons: Mr. J. Hutchinson, Mr. J. Couper, Mr. E. Nettleship, Sir John Tweedy, and Mr. W. Tay. Physician: Dr. J. Taylor. Surgeons: Mr. R. M. Gunn, Mr. W. Lang, Mr. J. B. Lawford, Mr. A. S. Morton, Mr. E. T. Collins, and Mr. W. T. H. Spicer. Assistant Surgeons: Mr. P. Flemming, Mr. J. H. Fisher, Mr. A. Lawson, Mr. C. D. Marshall, Mr. J. H. Parsons, and Mr. C. Werth. Medical Officer to the X Ray Department: Mr. J. M. Davidson. Curator and Librarian: Mr. G. Coats. Senior House Surgeon: Mr. C. Goulden. Second House Surgeon: Mr. A. C. Hudson. Third House Surgeon: Mr. Norman E. Gibbs. Refraction Assistants: Mr. T. Phillips, Miss W. Thorp, and Mr. G. T. Mould.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 40 free beds. Patients, who number over 11,000 annually, are seen at 1 P.M., and operations performed daily at 2 P.M. The following are the days of attendance of the surgeons: Mr. Hartridge and Mr. Grimsdale, Mondays and Thursdays; Mr. Roll and Mr. McMullen, Tuesdays and Fridays; and Mr. Dodd and Mr. Brewerton, Wednesdays and Saturdays. The practice of the hospital is open to practitioners and students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the posts of house surgeon and clinical assistants. Special demonstrations and lectures will be given during the session, commencing in October; for details see weekly journals. Clinical Assistants (who must be duly qualified) to the Surgeons are appointed for periods of six months. Secretary: Mr. John Hy. Johnson.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were 76,734 attendances in the Out-patient Department last year and the new patients numbered 26,150. Operations are performed and out-patients are seen daily at 9 A.M. and 2 P.M. The following are the days of attendance:—Afternoons: Mr. M. M. McHardy, Tuesdays and Thursdays; Sir William J. Collins, Mondays and Wednesdays; Mr. L. V. Cargill, Tuesdays and Fridays: and Mr. J. Strond Hosford, Mondays, Thursdays, and Saturdays. Mornings: Mr. E. Brooksbank James, Mondays and Thursdays; Mr. A. W. Ormond, Wednesdays and Saturdays; Mr. H. Willoughby Lyle, Tuesdays and Fridays. Qualified practitioners and students are admitted to the practice of the hospital upon the recommendation of the medical staff. Courses of instruction in Ophthalmology will be given during October, November, and December, 1907. Lectures will be delivered on Monday, Wednesday, and Friday evenings at 8 P.M. In addition special lectures or clinical demonstrations will be given by the hospital staff on dates to be announced. Fee for the course, £2 2s.; including three months' hospital practice, £3 3s. Tutorial or coaching classes for the various examinations arranged as far as possible to suit candidates. Further particulars may be obtained from the honorary secretary, Mr. A. W. Ormond.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—This hospital has 26 beds and possesses facilities for clinical teaching daily. Last year there were 355 in- and 12,910 out-patients (entailing 31,230 attendances). Classes of instruction in the various branches of Ophthalmology will be held during the winter session, commencing in October. The out-patient work begins at 1 o'clock and operations are performed daily between 1 and 4. Consulting Physician: Sir Dyce Duckworth. Surgeons: Mr. T. Brittin Archer, Mr. Ernest Clarke, Mr. A. P. L. Wells, and Mr. H. Parker. Assistant Surgeons: Mr. Ilbert Hancock and Mr. Stephen Mayou. Physician: Mr. Charles O. Hawthorne. Pathologist: Mr. Stephen Mayou. House Surgeon: Mr. G. Allison. Dentist: Mr. E. P. May. Secretary: Mr. H. R. S. Druce.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—In addition to the new In-patient Department, and operation theatre the hospital has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 10,052 out-patients (involving over 50,000 attendances) and 413 in-patients were treated. The fee for three months' attendance, 3 guineas; for six months, 5 guineas. The post-graduate teaching consists of successive series of practical demonstrations by the members of the staff delivered twice weekly during the winter and summer sessions. They are so arranged that practitioners joining at any part of the course are enabled to complete the group of subjects. The fee for each course is two guineas, with daily attendance at the out-patient department during the period of the course. Details of subjects, &c., will be afforded by the Dean. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages. Operation days: in-patients, Tuesday, Wednesday, Thursday, and Friday, at 2 P.M.; out-patients, daily at 9 A.M. Consulting Physician: Dr. Arthur Orwin. Consulting Surgeon: Mr. Thomas Nunn. Surgeons: Dr. Dundas Grant, Dr. Percy Jakins, Mr. Chichele Nourse, and Dr. Abercrombie. Assistant Surgeons: Mr. Stuart Low, Dr. Andrew Wylie, Dr. Atkinson, and Dr. McKenzie. Pathologist: Dr. Wyatt Wingrave. Bacteriologist: Mr. St. George Reid. Dental Surgeon: Mr. Whishaw Wallis. Anæsthetist: Mr. W. Hotten George. Assistant Anæsthetists: Mr. A. B. Kingsford, Dr. Lauzun-Brown, and Dr. MacKeith. In addition the following appointments are open to qualified members of the profession:—Three Registrars, tenable for twelve months; and twelve Clinical Assistants, tenable for six months. Secretary: Mr. Richard Kershaw. Dean: Dr. Wyatt Wingrave.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—Clinical Demonstrations on the Diseases of the Throat, Nose, and Ear are given daily at 2 P.M. and on Tuesday and Friday evenings at 6 P.M. Operations are performed almost daily at 9.30 A.M. Individual instruction is given in the examination of cases to students attending the hospital. Fees: one month's attendance, £1 1s.; three months, £2 2s.; perpetual, £5 5s. Detailed information may be obtained from the Hon. Secretary of the Medical Committee.

THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital was founded in 1838 and is situated in Grafton-street, Tottenham-court-road. The out-patient department is opened daily at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Tuesdays, Wednesdays, and Thursdays at 9.30 A.M. Fee for one month's attendance at the hospital £1 1s., and for three months £2 2s. During the forthcoming session practical demonstrations will be given by members of the staff on the diagnosis and treatment of diseases of the ear and respiratory passages. Each course may commence at any time.

ROYAL EAR HOSPITAL, Dean-street, Soho. (Founded 1816.)—Courses of instruction of a practical character in Diseases of the Ear and Nose are given by the members of the staff throughout the year. Clinical assistants are also appointed. The new hospital is now in full working order. Students may join at any time. For information address the Honorary Secretary of the Medical Board, Mr. T. H. Chaldecott.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, Henrietta-street, Covent-garden. Established 1860. New Hospital opened, 1882.—Honorary Surgeons: Mr. F. Swinford Edwards and Mr. P. J. Freyer. Assistant Surgeons: Mr. John Pardoe and Mr. J. W. Thomson Walker. The hospital contains 30 beds for men and 2 beds for women and children. Consultations are held and operations are performed each Wednesday and Friday at 2 P.M. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 25; average out-patients seen daily, 100.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C. Rebuilt 1905.—The in-patient department, 50 beds, is at 262, Uxbridge-road, W. The out-patient practice is open to the medical profession at the following times: Every day, from 2 to 4 P.M., and every evening (except Saturday) 6 to 8. Specially selected Clinical Demonstrations, also demonstrations on the different diseases presenting themselves in the out-patient department, followed by Lectures, will also be given. The x ray department is in operation every afternoon except Saturday. The Chesterfield Lectures are given on Thursdays at 6 P.M. October to March in the lecture room at 49, Leicester-square. The opening lecture will be given on Oct. 3rd. At the end of the course the Chesterfield silver medal may be competed for by those who have attended three-fourths of the lectures.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS) (LONDON which has recently been erected, is equipped upon the most approved principles and is thoroughly in accord with modern surgical requirements. Instruction in the Diseases of Women is given Tuesday and Friday at 10 A.M. by Sir Arthur V. Macan. There is a special wing devoted to fever cases. Pathological and Bacteriological Demonstrations will be given each Friday at 10 30 A.M. during the Winter and Summer Sessions in the new Pathological Laboratory. A new department has been opened for the special treatment of Throat, Nose, and Ear-diseases under the direction of Dr. R. H. Woods. Instruction will be given in these subjects and in the use of the Laryngoscope and Otoscope to senior students on Mondays and Thursdays. Opportunities are given the members of the hospital class of seeing the various applications of the x rays to the diagnosis and treatment of injury and disease. Opportunities are also afforded in the out-patient department for the diagnosis and treatment of the numerous minor ailments not met with in the hospital wards. Demonstrations are given upon Diseases of the Skin. A Resident Surgeon, with salary, is appointed annually. The election takes place at the end of December. Four Resident Pupils are appointed each half-year. Six Surgical Dressers and six Clinical Clerks are appointed each month.

Prizes and Medals.—Clinical medals and prizes will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit. The next examination will be held in April, 1908.

Fees.—Winter and summer session, £12 12*s.*; winter session (six months), £8 8*s.*; and summer session (three months), £5 5*s.* The practice of this hospital is open to students of Medicine in attendance on schools other than the School of Physic, the certificates being recognised by the Royal University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

Further information will be supplied by the Secretary to the Medical Board, Dr. H. C. Drury.

MERCER'S HOSPITAL.—This hospital, founded in 1707, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large out-patient department and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. Five Resident Pupils, each for six months, and Clinical Clerks and Dressers are appointed monthly from amongst the most deserving members of the class.

Fees.—Winter, six months, £8 8*s.*; Summer, three months, £5 5*s.*; nine months, £12 12*s.*

For further particulars apply to Dr. R. Charles B. Maunsell, 32, Lower Baggot-street, Dublin.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—Physicians: Sir John William Moore, Dr. James Craig, and Dr. Edward E. Lennon. *Surgeons*: Sir L. H. Ormsby, Mr. W. J. Hepburn, Mr. William Taylor, Mr. R. Lane Joynt, and Mr. F. Conway Dwyer. Gynæcologist: Dr. F. W. Kidd. Clinical Assistants: Dr. William Boxwell and Dr. Henry Stokes. Pathologist: Professor Arthur H. White. This hospital was founded in 1753 and now contains 160 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the Hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Six Medical Clinical Clerks and Twelve Surgical Resident Pupils and Dressers are appointed every six months, and a House Surgeon and two Clinical Assistants are elected annually. The session will open on Oct. 1st. A prospectus giving the complete arrangements for the Medical and Surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. William Taylor, 47, Fitzwilliam-square, Dublin.

MATER MISERICORDIÆ HOSPITAL, Dublin.—Consulting Physician: Sir Francis R. Cruise. Consulting Surgeon: Mr. Charles Coppinger. Physicians: Sir Christopher Nixon, Bart., Dr. Joseph Redmond, Dr. John Murphy, and Dr. Martin Dempsey. Surgeons: Sir Arthur Chance, Mr. John Lentaigne, and Mr. Alexander Blaney. Assistant Physician: Dr. John O'Donnell. Assistant Surgeon: Mr. Curran. Temporary Assistant Surgeon: Mr. D. Farnan. Obstetric Physician: Dr. Robert Farnan. Ophthalmic Surgeon: Mr. Louis Werner. Surgeon for Diseases of Throat and Nose: Mr. Patrick Dempsey. Dental Surgeon: Mr. E. Sheridan. Pathologist: Dr. Edmond McWeeney. Anæsthetist and Surgical Registrar: Dr. Patrick O'Farrell. This hospital, the largest in Dublin, at present containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays, and Saturdays at 11 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Two House Physicians, six House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training School and a Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes &c., may be obtained from the Secretary, Medical Board.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 270 beds—86 for Surgical cases, 64 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 12 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students, but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to Sir W. Thomson, C.B., Hon. Treasurer, 54, Stephen's-green East; or to Dr. Travers Smith, Hon. Secretary, 20, Lower Fitzwilliam-street, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest gynæcological as well as maternity hospital in the *British* empire. Qualified men who take out a course of two or three months' duration during the autumn, winter, or spring periods obtain (if they show keenness and capacity) one or more forceps applications and a certain number of minor gynæcological operations. Unqualified students can also enter at any time for the practice of the hospital and have access, not alone to the maternity and gynæcological wards, but also to the pathological laboratory attached to the hospital. The residential quarters have undergone considerable improvement and afford comfortable accommodation. Valuable appointments are periodically filled by qualified students who have obtained the hospital diploma. For further particulars apply to Mr. E. Hastings Tweedy, Master.

Heath, President of the University of Durham College of Medicine, bequeathed the sum of £4000 to found a Scholarship in Surgery, the interest to be awarded every second year; the next award will be in 1908. The Gibson Prize, interest on £225, in the department of Midwifery and Diseases of Women and Children. The Turnbull Prize and Medal for Surface Anatomy. At the end of each session Prizes of Books are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, Prosectors, and Assistant Demonstrators of Physiology and Pathology are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Throat and Ear Department, and Skin Department, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—This Infirmary was founded in 1751 but has been recently rebuilt, the new hospital being opened in 1906. The number of beds is 410. The number of in-patients annually is 4900 and of out-patients 51,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians and Assistant Surgeons weekly, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat and Ear, Skin, Orthopædic, Gynæcological, Electrical, and Bacteriological. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital, three large theatres, a smaller one for emergencies, and an out-patient theatre. The surgical practice is especially good; more than 4000 surgical operations were performed in the last 12 months. Every facility is given to students to take out the full or any part of the hospital curriculum, and clerkships or assistantships in any of the several special departments are open to undergraduates or graduates for periods of from one to three months. There are ten resident medical and surgical officers, two of whom are paid, and preference for these appointments is given to students who have fulfilled their curriculum in the hospital. The sessions open on May 1st and Oct. 1st of each year. Applications for detailed information should be made to the Dean, Dr. Thomas Beattie, at the hospital. The following is the staff of the hospital:—Physicians: Dr. David Drummond, Dr. Thomas Oliver, Dr. James Limont, and Dr. G. R. Murray. Assistant Physicians: Dr. Thomas Beattie and Dr. R. A. Bolam. Surgeons: Mr. J. R. Rutherford Morison, Mr. A. M. Martin, Mr. H. B. Angus, and Mr. J. V. W. Rutherford. Assistant Surgeons: Mr. W. G. Richardson, Mr. J. W. Leech, Mr. John Clay, and Mr. G. G. Turner. Ophthalmic Surgeon: Mr. J. D. Wardale. Throat and Ear Department: Surgeon: Mr. G. W. Ridley; Assistant Surgeon: Mr. S. H. Whillis. Gynæcological Department: Dr. R. P. R. Lyle. Skin Department: Physician: Dr. James Limont; Assistant Physician: Dr. D. W. Patterson. Orthopædic Depart-ment: Mr. A. M. Martin. Electrical Department: Dr. W. D. Arnison. Pathologist: Dr. R. A. Bolam. Bacteriologist: Dr. H. J. Slade. Pathological and Analytical Chemist: Mr. P. P. Bedson, D.Sc. Anæsthetists: Dr. R. Younger, Dr. F. G. Armstrong, Dr. L. S. Davison, and Dr. H. H. Markham. Medical Registrars: Dr. W. E. Moore-Ede and Dr. W. Simpson. Surgical Registrars: Mr. J. W. Heslop and Mr. A. Parkin.

There are other institutions at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Northumberland County Asylum, Morpeth. A special course of instruction is given in the City Hospital for Infectious Diseases by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong.

NORTHUMBERLAND, DURHAM, AND NEWCASTLE INFIRMARY FOR DISEASES OF THE EYE, St. Mary's-place, Newcastle-on-Tyne.—Consulting Surgeon: Mr. F. Page. Staff Surgeons: Mr. A. S. Percival and Mr. H. P. Bennett. Assistant Surgeons: Mr. Andrew Messer and Mr. J. B. Hartley. Honorary Anæsthetists: Dr. O. W. Ogden and Mr. T. H. Livingstone. Matron: Miss O. Crump. Secretary: Mr. Richard Smith, 61, Westgate-road, Newcastle-on-Tyne. Out-patients for 1906, 6573; in-patients, 345.

THE VICTORIA UNIVERSITY OF MANCHESTER: MEDICAL FACULTY.—This medical school is located in a large building, which forms a part of the University. It is provided with large dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, a large extension of the school buildings was made in 1895. The greater part of the new buildings is devoted to the departments of physiology, pathology, toxicology, anatomy, and public health. The physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. In the toxicological department there is a large laboratory, capable of accommodating 50 students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology; also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry. In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology. A large room is provided in the new buildings for a museum of apparatus, models, plans, and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics, and sanitary engineering. In addition, a large lecture theatre for general purposes, accommodating 250 students, has been provided, and the existing accommodation for students is supplemented by the provision of a larger common room. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, as well as in a fever hospital a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following entrance scholarships are offered for award to persons of either sex proposing to enter a medical course of study at the University:—Seaton—One of £40, tenable for two years. Subjects: Greek and Latin Translation at sight, and Prose Composition. Credit given for knowledge of Mathematics (Geometry and Algebra); Elements of English Language, Literature, and History; French and German. Rogers.—One of £40, tenable for two years. Subjects as in Seaton. Dalton.—Two of £40, tenable for two years. Subjects: Geometry (Euclid I.—IV., and VI., or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics, Elements of English Language, Literature, and History; French and German. Cartwright.—£35 per annum, tenable for three years Subjects as in Dalton. Hulme.—£35, tenable for three years. Subjects: English Language (Grammatical Structure and Outlines of its History); English Literature (an essay on some subject of English literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight, Grammar, and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). Dora Muir.—£25 per annum, tenable for three years (open to women only). Candidates may select such of the subjects as they desire from

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
CHARING-CROSS HOSPITAL AND COLLEGE—*continued.*	Epsom Scholarship.	Free education.	——	.....	Epsom Foundation Scholars who have passed Preliminary Scientific M.B. Lond. Univ.
	Universities Scholarship (1) Universities Scholarship (2)	72 guineas. 72 "	——	Examination in ANATOMY and PHYSIOLOGY, including HISTOLOGY.	Oxford Students who have passed first M.B. Exam. Cambridge students who have passed second M.B. Exam. London students who have passed Intermediate Exam. in Med. who have not entered at any London Medical School.
	Llewellyn Scholarship.	£25	——	Awarded annually to the Student of not more than five years' standing who, in the opinion of the School Committee, shall have distinguished himself the most at the Prize Examinations in the following subjects, viz.:—MEDICINE, SURGERY, MIDWIFERY, PATHOLOGY, THERAPEUTICS, FORENSIC MEDICINE, PUBLIC HEALTH, PSYCHOLOGICAL MEDICINE, OPHTHALMOLOGY, PRACTICAL MEDICINE, PRACTICAL MIDWIFERY.	None.
	Huxley Medal with Prize.	£10.	——	Competitive Examination in ANATOMY and PHYSIOLOGY at end of Second Winter Session.	......
	Golding Prize.	£10.	——	Competitive Examination among First-year Students in ANATOMY and PHYSIOLOGY.	Students must have attended the Classes in each subject at this School.
	The Dr. T. H. Green Prize for Clinical Medicine.	5 guineas.	......	Given annually to the Student who does the best work upon some special subject involving simple clinical observation in the wards or clinical laboratory and on the result of a practical examination on cases in the wards.	......
ST. GEORGE'S HOSPITAL—	Entrance Scholarships. No. 1.	70 guineas	——	Competitive Examination in ANATOMY and PHYSIOLOGY.	......
	" No. 2.	£50.	——	Ditto.	......
	Wm. Brown Exhibition.	£100 per annum.	2 years.	Competitive Examination among Perpetual Pupils having registrable qualification in the PRACTICE OF MEDICINE, MIDWIFERY, and SURGERY.	Study at St. George's School.
	"	£40 " "	3 years.	Competitive Essay and Submission of Original Work by Perpetual Pupils qualified not more than three years previously.	Ditto.
	Allingham Scholarship in Surgery.	Interest on £1800.	——	Competitive Essay for Students qualified not more than three years.	....
	Brackenbury Prize in Medicine.	Interest on £1103.	——	Competitive Examination among Students of not more than five years' standing.	None.
	Brackenbury Prize in Surgery.	Interest on £1103.	——	Competitive Examination among Students of not more than five years' standing	None.
	Treasurer's Prize.	£10 10s.	——	Proficiency in Clinical Examination of three Medical and three Surgical Cases, together with a written Examination in Medicine, Surgery, and Midwifery.	None.
	H. C. Johnson Memorial Prize.	£10 10s.	——	Competitive Examination in PRACTICAL ANATOMY.	None.
	Pollock Prize.	Interest on £372.	——	Competitive Examination in PHYSIOLOGY, PHYSIOLOGICAL CHEMISTRY, and HISTOLOGY.	None.
	Clarke Prize. Thompson Medal. Brodie Prize.	Interest on £209. Interest on £185. Interest on £220.	—— —— ——	Awarded for Clinical Reports and Commentaries.	None.
	Webb Prize.	Interest on £1000.	——	Competitive Examination among Perpetual Pupils in BACTERIOLOGY.	None.
GUY'S HOSPITAL—	Entrance Scholarships. No. 1.	£100.	——	Open Competitive Examination among Candidates under twenty years of age in LATIN, ENGLISH, GREEK or FRENCH or GERMAN, ARITHMETIC, EUCLID, and ALGEBRA.	Course at Guy's Hospital.

Honorary Anæsthetists: Mr. G. A. Barrow and Dr. H. R. Clarke. Pathologist: Dr. J. Garvie McNaughton. Assistant Medical Officers: Dr. A. W. Lilley and Mr. R. W. Walsh. Honorary Dentist: Mr. W. A. Hooton. House Surgeon: Mr. George H. Leigh.

THE UNIVERSITY OF LIVERPOOL: FACULTY OF MEDICINE.—Students may enter for the degrees of the University of Liverpool or study for the degrees and qualifications of the various other licensing bodies. The conditions as to degrees will be found on p. 583 under the heading of the University of Liverpool.

Medical School Buildings.—Spacious and well-equipped class-rooms and laboratories have been erected for the practical study of all the important scientific subjects which form the basis of medicine. Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. The most recent additions are the Johnston Laboratories for Experimental Medicine, Bio-chemistry, and Comparative Pathology and the new building for Anatomy, Surgery, Toxicology, Ophthalmology and Dental subjects, which has just been completed. The departments of Physiology and Pathology are accommodated in the large block provided by the generosity of the late Rev. S. A. Thompson Yates in 1898. The Anatomical department is situated in a separate block and has a complete suite of rooms, including a large and well-stocked museum and a well-lighted dissecting room on the upper floor measuring 70 by 40 feet.

Hospitals.—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye and Ear Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of 1127 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access from the University; those which are situated at any distance are readily reached by the tramway service of the city. The period of hospital practice extends over the last three years of medical study. During the first two years of this period no student will be permitted to change his attendance from one general hospital to another except at the commencement of an academic term. It is a regulation of the school that not more than five of the six terms of these two years shall be spent at any single general hospital. During the final year of hospital practice a student is permitted to attend the practice of all the general hospitals without restriction. The regulations demand only that his attendance shall be regular and to the satisfaction of the hospital's board. There are a large number of appointments to house physicianships and surgeonships both at the general and special hospitals which are open to qualified students of the school. These appointments (20) in most cases carry salaries ranging from £60 to £100 per annum. Applications for further information regarding the Clinical School should be addressed to the Dean of the Faculty of Medicine.

Fellowships and Scholarships.—Fellowships, scholarships, and prizes of over £1000 are awarded annually. A Holt Fellowship in Pathology and Surgery of the value of £100 for one year is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. The successful candidate is required to devote a year to tutorial work and investigation in the pathological department. A Holt Fellowship in Physiology, awarded under similar conditions of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, also of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynæcological Pathology (£100 a year, renewable). A Stopford Taylor Fellowship (£100 a year, renewable) in Dermatology. A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. A further scholarship in Surgical Pathology (£50 per annum, renewable). Two Lyon Jones Scholarships of the value of £21 each for two years are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students, on the subjects of the First M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, on the subjects of Anatomy, Physiology, and Therapeutics. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. In 1907 the subject will be Clinical Medicine. The Torr Gold Medal in Anatomy, the George Holt medal in Physiology, the Kanthack Medal in Pathology, the Robert Gee Book Prize, of the value of £5, for Children's Diseases, and numerous Class Prizes are awarded annually.

Entrance Scholarships.—Two Robert Gee Entrance Scholarships of the value each of £25 per annum for two years are offered annually for competition. The holder is required to take out the Science Course for the University Degree in Medicine. Communications should be addressed to the Dean, Professor Benjamin Moore, The University, Liverpool.

School of Tropical Medicine.—The school is affiliated with the University of Liverpool and the Royal Southern Hospital of Liverpool. Three courses of instruction are given every year, commencing on Jan. 14th, May 1st, and Oct. 1st, and lasting for the academical term of about ten weeks. Each course consists (1) of a systematic series of lectures on Tropical Medicine and Sanitation delivered by the Professor of Tropical Medicine at the University; (2) of additional lectures on Cytology, Special African Diseases, and Special Indian Diseases, delivered at the University; (3) of systematic lectures and demonstrations on Tropical Pathology, Parasitology, and Bacteriology by the Walter Myers Lecturer at the University; (4) of similar instruction on Medical Entomology by the Lecturer on Economic Entomology at the University; and (5) of clinical lectures and demonstrations delivered at the Royal Southern Hospital by the Physician in charge of the Tropical Ward, the Professor, and the Walter Myers Lecturer. The instruction given occupies six hours a day for five days a week during the term. Teaching under headings 3 and 4 above is delivered in the laboratory of the school at the University, which contains accommodation for 30 students, with all necessary appurtenances, including a well-equipped museum, a class library, and access to the general departmental library. Teaching under heading 5 is given in the tropical ward and the attached clinical laboratories of the Royal Southern Hospital on two or three afternoons a week. At the end of each term an examination is held by the University for its diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examinations lasts three days and consists (1) of three papers on Tropical Medicine, Tropical Pathology, and Tropical Sanitation and Entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The results are declared as soon as possible afterwards. Those who do not wish to undertake the examination are given a certificate of attendance if their attendance has been satisfactory. Accommodation for a limited number of students may be had at the Hall of Residence (for terms apply to the Warden, 44, Upper Parliament-street). The fee for the full course of instruction is 10 guineas, with an extra charge of 10*s.* for the use of a microscope if required. The fee for the examination is 5 guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool, from whom prospectuses may be obtained. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had both at the University Laboratory of the school and at its Research Laboratories at Runcorn (16 miles distant from Liverpool). Since it was instituted nine years ago the school has employed 25 different investigators paid out of its funds and has despatched to the tropics 17 scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in 21 special memoirs with many plates and figures, besides text-books and

Dr. Edward Malins. Physicians: Dr. Robert Saundby, Dr. Robert M. Simon, Dr. T. Stacey Wilson, and Dr. T. Sydney Short. Surgeons: Sir Thomas F. Chavasse, Mr. Gilbert Barling, Mr. William F. Haslam, and Dr. George Heaton. Obstetric Physician: Dr. Thomas Wilson. Ophthalmic Surgeon: Dr. D. C. Lloyd-Owen. Aural Surgeon and Laryngologist: Dr. F. W. Foxcroft. Physician in Charge of Skin Department; Dr. A. Douglas Heath. Assistant Physicians: Dr. James W. Russell and Dr. A. Stanley Barnes. Assistant Surgeons: Mr. Albert Lucas and Mr. Leonard P. Gamgee. Assistant Obstetric Physician: Dr. John T. Hewetson. Casualty Assistant Physicians: Dr. William H. Wynn and Dr. J. E. Sawyer. Visiting Pathologist: Dr. James Miller. Anæsthetists: Dr. Sydney Haynes and Dr. W. J. McCardie. Casualty Assistant Surgeons: Mr. F. Victor Milward and Mr. Frank Barnes. Surgical Photographer and Radiographer: Mr. J. Hall Edwards. Dental Surgeon: Mr. A. T. Hilder.

At the Queen's Hospital similar arrangements for clinical teaching are made, and the material here also is excellent, though the institution is, of course, much smaller. Ward and tutorial classes are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons.

Staff of Queen's Hospital.—Consulting Physicians: Sir James Sawyer, Dr. C. W. Suckling, and Dr. A. H. Carter. Consulting Surgeons: Mr. Furneaux Jordan, Mr. Frank Marsh, Mr. J. St. S. Wilders, and Mr. Bennett May. Consulting Ophthalmic Surgeon: Mr. Priestley Smith. Physicians: Dr. Arthur Foxwell, Dr. O. J. Kauffmann, and Dr. J. Douglas Stanley. Surgeons: Mr. Jordan Lloyd, Mr. J. T. J. Morrison, and Mr. O. A. Leedham-Green. Ophthalmic Surgeon: Mr. Wilfrid Allport. Obstetric Physician: Dr. C. E. Purslow. Physicians for Out-patients: Dr. Joseph George Emanuel and Dr. L. G. J. Mackey. Surgeons for Out-patients: Mr. W. Billington and Mr. A. W. Nuthall. Pathologist: Dr. L. G. J. Mackey.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Honorary Consulting Physician: Dr. R. Saundby. Honorary Consulting Surgeon: Mr. D. C. Lloyd-Owen. Surgeons: Mr. H. Eales, Mr. E. W. Wood-White, and Mr. J. Jameson Evans. Dental Surgeon: W. T. Madin, L.D.S. Anæsthetist: Dr. S. W. Haynes. This hospital possesses 105 beds, and there is an average daily attendance of out-patients of 213. This institution is recognised by Universities and the Royal College of Surgeons, England, and Royal College of Physicians, London, as an ophthalmic hospital at which clinical instruction in ophthalmology may be received. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations.

THE SCHOOL OF MEDICINE: MEDICAL FACULTY OF THE UNIVERSITY OF LEEDS.—The Leeds General Infirmary, in connexion with this medical faculty, has accommodation for 524 in-patients, including 96 beds at "semi-convalescent" homes in the country. During the last year 6445 in-patients and 38,660 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electrical, Finsen Light, and X-ray Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Hospital for Women and Children, the Fever Hospital, the Maternity Home, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds Students. Thirteen years ago the new buildings of the Medical School were opened. Placed closed to the Infirmary, the School of Medicine contains complete accommodation for the training of medical students upon the most approved modern methods. A very fine dissecting-room, extensive laboratories for Physiology and Pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large Library, and separate Museums for Pathology and Anatomy are some of the most striking features of the buildings. Provision for the convenience of students, in the shape of a common room, a refectory, &c., are made. The classes in Systematic and Practical Chemistry, Physics, Botany, and Zoology, are held in the Science and Arts Department of the University, in College-road. Two Entrance Scholarships are offered: one, of the value of £73 2*s.* 6*d.*, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the Infirmary are annually open to students (for some of them, however, a registered legal qualification is required): Non-resident: clinical pathologist, £200; senior anæsthetist, £50; 5 anæsthetists, £25. Resident: medical officer, £150; surgical officer, £150; casualty officer, £125; ophthalmic, £100. These appointments are made annually and holders are eligible for re-election. Resident medical officer to the Ida Hospital, for six months; honorarium £30. Six house physicians, for six months; 7 house surgeons, for six and 12 months; 24 physicians' clerks, for six months; 24 surgeons' dressers, for six months; 16 ophthalmic and aural surgeons' dressers, for three months; 12 gynæcological ward clerks, for three months: 16 gynæcological out-patient clerks, for three months; 24 maternity clerks, for one month; 24 assistant physicians' clerks, for three months; 8 dermatological clerks, for three months; 8 laryngological clerks, for three months; 24 assistant surgeons' dressers, for three months; 8 assistant ophthalmic surgeons' dressers, for three months; 24 dressers in the casualty-room, for three months; 24 post-mortem room clerks, for three months; 8 laboratory assistants, for three months. There are appointments open to students in other medical institutions in the town and also in the West Riding (Lunatic) Asylum.

Staff of Leeds General Infirmary.—Consulting Physicians: Dr. T. O. Allbutt, Dr. J. E. Eddison, and Dr. C. M. Chadwick. Physicians: Dr. T. Churton, Dr. A. G. Barr, and Dr. T. W. Griffith. Assistant Physicians: Dr. E. F. Trevelyan and Dr. W. H. M. Telling. Consulting Obstetric Physician: Dr. J. Braithwaite. Obstetric Physician: Dr. J. B. Hellier. Consulting Surgeon: Mr. C. G. Wheelhouse, Mr. T. P. Teale, Mr. T. R. Jessop, and Mr. A. W. M. Robson. Surgeons: Mr. E. Ward, Mr. W H. Brown, Mr. H. Littlewood, and Mr. R. L. Knaggs. Assistant Surgeons: Mr. B. G. A. Moynihan and Mr. W. Thompson. Consulting Surgeon to the Eye and Ear Department: Mr. J. A. Nunneley. Surgeons: Mr. H. S. Walker and Mr. A L. Whitehead. Assistant Surgeon: Mr. G. O. Hayes. Consulting Dental Surgeon: Mr. T. S. Carter. Dental Surgeon: Mr. J. B. Horden. Anæsthetists: Mr. D. Seaton, Mr. W. C. Mayo, Mr. J. Nicholson, Mr. R. Hopton, Mr. H. Collinson, and Mr. C. Johnstone.

UNIVERSITY OF SHEFFIELD: FACULTY OF MEDICINE.—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical department occupies the entire north wing of the University quadrangle. The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The Royal Infirmary, containing 255 beds, with an annual average number of over 3800 in-patients, over 8000 out-patients, and over 21,000 casualties; the Royal Hospital, with 165 beds, and an annual number of 2500 in-patients, over 7000 out-patients, and over 14,000 casualties; and the Jessop Hospital for Diseases of Women, with 80 beds, nearly 500 in-patients, and over 2000 out-patients; also a Maternity department, with over 250 in-patients per annum and over 700 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (547 beds) and on Mental Diseases at the South Yorkshire Asylum (1610 beds). For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 420 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at such institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopædics, and Mental Diseases. During the last year over 6000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 45,000. The medical and surgical staffs attend daily and give clinical instruction in the wards and out-patient rooms at stated times. Clinical lectures in Medicine and Surgery are given weekly at stated times. Instruction in the practical administration of anæsthetics is

Professor Francis Francis. Practical Bacteriology: Professor A. F. Stanley Kent. Comparative Anatomy: Professor C. Lloyd Morgan. Dental Anatomy and Physiology and Dental Histology: Mr. E. A. G. Dowling. Dental Bacteriology: Professor I. Walker Hall. Dental Surgery and Practical Dental Surgery: Mr. W. R. Ackland. Dental Mechanics and Dental Metallurgy and Practical Dental Metallurgy: Dr. C. A. Hayman. Composition fee for lectures and hospital practice, 133 guineas. Composition fee for Dental lectures and surgical practice, 75 guineas; for two years' instruction in Mechanical Dentistry, 75 guineas; if whole curriculum be taken the composition fee is 140 guineas. Special six months' course for Diploma in Public Health. 1. Lectures on Public Health: Dr. D. S. Davies. 2. Bacteriology: Professor A. F. Stanley Kent. 3. Laboratory Course of Hygienic Chemistry: Mr. F. W. Stoddart. 4. Demonstrations on the Various Acts, Orders, By-laws, &c.: Mr. J. C. Heaven. 5. Practical Outdoor Sanitary Work: Dr. D. S. Davies. Fee for the entire course 25 guineas. The prizes and scholarships in connexion with the Bristol Medical School will be found on p. 637. Full information can be obtained on application to the Dean, Professor Edward Fawcett, University College, Bristol.

Professors—Chemistry: F. Francis, D.Sc. Experimental Physics: A. P. Chattock. Zoology: S. H. Reynolds, M.A. Psychology: C. Lloyd Morgan, LL.D., F.R.S. Medicine: F. H. Edgeworth, M.B., and J. Michell Clarke, M.D. Surgery: C. A. Morton, F.R.C.S., and J. Swain, F.R.C.S. Anatomy: E. Fawcett, M.D. Physiology and Histology: A. F. Stanley Kent, M.A. Midwifery: W. C. Swayne, M.D. Pathology: I. Walker Hall.

The Royal Infirmary, Bristol, has 270 beds, the number of in-patients is 4000, and the number of out-patients 45,000 annually. There are separate wards for diseases of children, eye cases, diseases of women, and diseases of throat and nose. The Pathological and Bacteriological Departments have been newly equipped and are under the direction of the pathologist. In clinical pathology a special room is set apart for the exclusive use of students and research workers, and post-graduate courses may be taken over by arrangement with the pathologist. The Dental Department has been entirely re-organised. In the Pharmaceutical Department special classes are held by the pharmacist. Clinical appointments: All students must undergo before holding Clinical appointments preliminary instruction for three months in pathological, medical, surgical, and dental methods of diagnosis, &c. Pathological Clerkship for three months. Surgical Dresser for six months: the dressers reside in the Infirmary free of expense in rotation a week at a time, taking a part in the whole daily routine of surgical work. Medical Clerk for six months; Obstetric Clerk for three months; Ophthalmic Clerk for three months. In other special departments attendance is made during the fifth year of study. A convenient students' room is provided. Resident appointments: The posts of House Surgeon, House Physician, Resident Obstetric Officer, Junior House Surgeon, and Casualty Officer are all salaried. The two senior posts are usually held for one, two, or more years, the obstetric post is held for 12 months, and the two junior posts are tenable for six months each. Honorary and Consulting Physicians: Dr. W. H. Spencer, Dr. R. Shingleton Smith, and Dr. H. Waldo. Honorary and Consulting Surgeons: Mr. E. C. Board, Mr. W. H. Harsant, and Mr. A. W. Prichard. Honorary and Consulting Ophthalmic Surgeon: Mr. F. Richardson Cross. Honorary Physicians: Dr. J. E. Shaw, Dr. A. B. Prowse, Dr. P. Watson Williams, and Dr. F. H. Edgeworth. Honorary Surgeons: Mr. J. Paul Bush, Mr. G. Munro Smith, Dr. J. Swain, and Mr. T. Carwardine. Honorary Ophthalmic Surgeon: Dr. Ogilvy. Honorary Obstetric Physician: Dr. Walter Swayne. Honorary Dental Surgeon: Mr. W. R. Ackland. Honorary Assistant Dental Surgeon: Dr. Charles A. Hayman. Honorary Assistant Physicians: Dr. J. R. Charles and Dr. J. A. Nixon. Honorary Assistant Surgeons: Mr. H. F. Mole and Mr. E. H. E. Stack. Pathologist: Dr. I. Walker Hall. Honorary Demonstrator of Morbid Anatomy: Dr. J. J. S. Lucas. Honorary Anæsthetist: Mr. A. L. Fleming. Honorary Assistant Anæsthetist: Mr. S. V. Stock. Honorary Skiagraphist: Mr. James Taylor. House Surgeon and Senior Resident Medical Officer: Dr. A. Rendle Short.

Bristol General Hospital.—Number of beds 200; number of in-patients over 2000; number of out-patients about 40,000 annually. The arrangements are practically similar to those at the Royal Infirmary. Honorary and Consulting Physician: Dr. A. J. Harrison. Honorary and Consulting Surgeons: Mr. Robert W. Coe, Dr. George F. Atchley, Mr. Nelson C. Dobson, Mr. F. Poole Lansdown, and Mr. Chas. F. Pickering. Physicians: Dr. J. Michell Clarke, Dr. George Parker, and Dr. J. O. Symes. Surgeons: Mr. C. A. Morton, Dr. R. G. Poole Lansdown, Dr. J. Lacy Firth, and Dr. H. Greville Kyle. Physician Accoucheur: Dr. W. H. C. Newnham. Physician to Department for Diseases of the Skin: Dr. W. Kenneth Wills. Surgeon to the Throat and Nose: Dr. J. Lacy Firth. Ophthalmic Surgeon: Mr. Cyril H. Walker. Assistant Physicians: Dr. Newman Neild and Dr. Carey F. Coombs. Assistant Surgeon: Mr. E. W. H. Groves. Assistant Physician Accoucheur: Mr. D. C. Rayner. Anæsthetists: Mr. J. Freeman and Mr. Hedley Hill. Dental Surgeon: Mr. T. Taylor Genge. Pathologists: Dr. J. Michell Clarke and Dr. Newman Neild. Curator of Museum: Dr. Coombs. Bacteriologist: Dr. J. O. Symes. Skiagraphist: Mr. J. Ellington Jones.

Resident Appointments.—There are five resident appointments in the Hospital, and the Dressers reside in rotation, free of expense. The Maternity students also have rooms provided in the institutions.

Fees.—Medical Practice: three months, 4 guineas; six months, 7 guineas; one year, 12 guineas; perpetual, 20 guineas. Surgical Practice: three months, 4 guineas; six months, 7 guineas; one year, 12 guineas; perpetual, 20 guineas. Medical and Surgical Practice together in one payment: six months, 12 guineas; one year, 20 guineas; perpetual, 35 guineas. Dental Surgical Practice: one year, 7 guineas; perpetual, 12 guineas. The above fees include Clinical Lectures. Clinical Clerkship: 5 guineas for six months. Dressership: 5 guineas for six months. Museum fee: 3 guineas (composition on entrance), or 1 guinea annually. Dispensing Fee: 2 guineas. Students from other schools or qualified medical men wishing to attend Clinical Practice for short periods and not requiring certificates for such attendance may do so for the following fees:—Medical and Surgical Practice conjointly: one month, 2 guineas; two months, 3 guineas; three months, 4 guineas; and six months, 7 guineas.

Further information may be obtained on application to the Dean of the Faculty.

University of Wales: Medical Faculty.—Under the heading of the University of Wales we have already mentioned that that University does not yet possess the privilege of granting degrees in medicine. Welsh medical students can attend the practice of the Cardiff Infirmary. This infirmary contains 178 beds. Consulting Physicians: Dr. W. T. Edwards, Dr. William Taylor, and Dr. C. T. Vachell. Consulting Surgeon: Dr. T. Wallace. Consulting Dental Surgeon: Mr. John C. Oliver. Physicians: Dr. H. R. Vachell and Dr. A. E. Taylor. Surgeons: Mr. P. Rhys Griffiths, Mr. William Sheen, and Mr. J. Lynn Thomas, C.B. Assistant Physicians: Dr. W. Mitchell Stevens, Dr. Cyril Lewis, and Dr. Alfred Howell. Assistant Surgeons: Mr. H. G. Cook, Mr. Cornelius A. Griffiths, and Mr. William Martin. Ear, Throat, and Nose Surgeon: Dr. D. R. Paterson. Consulting Ophthalmic Surgeon: Mr. J. T. Thompson. Ophthalmic Surgeon: Mr. H. C. Ensor. Assistant Ophthalmic Surgeons: Mr. F. P. S. Cresswell and Mr. R. Russell Thomas. Gynæcologists: Dr. Ewen J. Maclean and Dr. E. Tenison Collins. Pathologist: Dr. W. Mitchell Stevens. Bacteriologist and Assistant Pathologist: Dr. H. A. Schölberg. Sanitary Adviser: Dr. E. Walford. Anæsthetists: Dr. Fredk. W. S. Davies, Dr. W. G. Williams, and Dr. Alex. Brownlee. Dental Surgeons: Mr. T. W. Kittow and Mr. Thomas Quinlan. Resident Medical Officer: Dr. W. R. Spencer Watkins.

Wolverhampton and Staffordshire General Hospital.—There are 230 beds. It is recognised by the University of London, the Royal Colleges of Physicians and Surgeons, and other examining boards. The in-patients number 2550; the out-patients 19,985. Special departments for Children, Gynæcology, Ear, Throat, and Nose Diseases, Electro-therapeutic and X Ray departments. There is an excellent library. The resident officers are a senior house physician, senior house surgeon, house physician, and house surgeon. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and

and Public Boards. A post-graduate vacation course commences on Sept. 2nd.

The anatomy rooms and laboratories will open on Tuesday, Oct. 1st. On Tuesday, Oct. 15th, the lectures will commence.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have held the office of clerk in their wards for at least six months. Six Residentships are appointed for a period of six months each. Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital. In all respects the students are taught under regulations similar to those at the University *of Edinburgh* and the other Universities of Scotland, and they receive similar certificates at the close of each session. Moreover, the University and College authorities in Edinburgh and the governing board of the school call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class. The courses on special non-qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally. A list of the classes and lecturers will be found below. Special courses of instruction for dental students and for women are also included in the curriculum of this school. The classes of the school are conducted in several separate buildings, such as at Surgeons' Hall, Minto House, Nicolson-square, and the New School, Bristo-street.

Lecturers and fees.—Winter Session: Anatomy, Practical Anatomy, and Demonstrations, Dr. Ryland Whitaker (£3 5*s.* and £4 4*s.*); Chemistry (Practical, &c.), Mr. King, Mr. Gemmell, and Dr. T. W. Drinkwater*; Physiology (Institutes of Medicine) Dr. Alex. Goodall; (£3 5*s.*); General Pathology, &c., Dr. Russell, Dr. Shennan, and Dr. Stuart McDonald (£3 5*s.*); Biology, Mr. Malcolm Laurie (£3 5*s.*); Zoology, Mr. Malcolm Laurie; Physics, Dr. Dawson Turner (£3 3*s.*); Bacteriology, Dr. Taylor Grant, Dr. Theodore Shennan, and Dr. Stuart McDonald: Practice of Physic, Dr. James, Dr. Bramwell, Dr. Gibson, Dr. Bruce, Dr. Philip, Dr. R. A. Fleming, Dr. Lovell Gulland, and Dr. Harry Rainy (£3 5*s.*): Surgery, Mr. Caird, Mr. Hodsdon, Mr. Thomson, Mr. Wallace, Mr. Miles, Mr. Scot Skirving, Mr. Dowden, and Mr. Chiene (£3 5*s.*); Materia Medica, &c., Dr. Craig† and Dr. F. D. Boyd (£3 5*s.*); Midwifery, &c., Dr. Hart, Dr. Haultain, Dr. Ballantyne, Dr. Fordyce, Dr. Elsie M. Inglis, and Dr. Campbell (£3 5*s.*); Medical Jurisprudence, &c., Dr. Aitchison Robertson (£3 5*s.*); Public Health, Dr. Aitchison Robertson and Dr. W. Robertson; Hospital Practice (Edinburgh Royal Infirmary): Physicians, Dr. James, Dr. Bramwell, Dr. Gibson, and Mr. Brewis for Gynæcology; Surgeons, Mr. Cotterill, Mr. Cathcart, and Mr. Caird (perpetual ticket, £12); Clinical Medicine, Dr. James, Dr. Byrom Bramwell, and Dr. Gibson £3 5*s.*): Clinical Surgery, Mr. Cotterill, Mr. Cathcart, and Mr. Caird (£3 5*s.*); Diseases of the Chest, Dr. Philip† and Dr. Lovell Gulland (£2 2*s.*); Vaccination, Dr. Buist† (£1 1*s.*); Diseases of Ear, Nose, and Throat, Dr. J. Malcolm Farquharson and Dr. J. S. Fraser (£2 2*s.*): Diseases of the Eye, Dr. Sym,† and Dr. A. H. H. Sinclair (£2 2*s.*); Gynæcology, Dr. Haig Ferguson and Dr. Elsie M. Inglis (Systematic), Dr. Brewis and Dr. J. Haig Ferguson (Clinical), and Dr. Berry Hart (Advanced) (£2 2*s.*); Diseases of the Blood, Dr. G. Lovell Gulland; Neurology, Dr. J. J. Graham Brown (£2 2*s.*): Diseases of the Chest, Dr. Philip and Dr. Lovell Gulland (£2 2*s.*); Medical Electricity, Dr. Dawson Turner (£2 12*s.* 6*d.*); Tropical Diseases, Major D. G. Marshall, I.M.S. (£2 2*s.*). Summer Session: Practical Anatomy and Demonstrations, Dr. Ryland Whitaker (£2 2*s.*); Practical Physiology, Dr. Goodall (£3 3*s.*); Biology, Mr. M. Laurie‡ and Miss Newbigin (£3 3*s.*); Practical Chemistry and Analytical Chemistry, Mr. King, Mr. Gemmell, and Mr. Drinkwater §; Practical Bacteriology, Dr. Shennan, Dr. Taylor Grant, and Dr. Stuart McDonald; Materia Medica, Dr. Craig and Dr. F. D. Boyd; Diseases of the Eye, Dr. Sym and Dr. A. H. H. Sinclair (£2 2*s.*); Medical Psychology and Insanity, Sir J. Batty Tuke and Dr. Robertson (£2 2*s.*); Medical Jurisprudence, Dr. Aitchison Robertson; Public Health, Dr. Wm. Robertson (£2 2*s.*); Gynæcology, Dr. Brewis and Dr. Ballantyne (£2 2*s.*); Midwifery, Dr. Ferguson, Dr. Ballantyne, Dr. Fordyce, Dr. Elsie M. Inglis, and Dr. Campbell (£3 5*s.*); Operative Surgery, Mr. Caird, Mr. Hodsdon, Mr. Alexis Thomson, Mr. David Wallace, Mr. Alex. Miles, and Mr. Dowden (£3 3*s.*); Practical Pathology, Dr. Russell, Dr. Shennan, and Dr. Stuart McDonald (£3 3*s.*); Physics, Dr. Turner‡ (£3 3*s.*); Practical Medicine and Physical Diagnosis, Dr. Philip, Dr. Fleming, and Dr. Lovell Gulland (£3 3*s.*); Practice of Medicine, Dr. James, Dr. Bramwell, and Dr. Gibson (£2 2*s.*); Vaccination, Dr. Buist (£1 1*s.*); Neurology, Dr. Bruce and Dr. Graham Brown; Diseases of Ear, Nose, and Throat, Dr. J. Malcolm Farquharson and Dr. J. S. Fraser (£2 2*s.*); Tropical Diseases, Major D. G. Marshall, I.M.S. (£2 2*s.*); Medical Electricity, Dr. Dawson Turner.

Special Classes for Women, Winter Session: Practical Anatomy and Demonstrations, Dr. Ryland Whitaker (£4 4*s.*); Chemistry (Lectures and Practical), Dr. T. W. Drinkwater (£3 5*s.* and £3 3*s.*); Practice of Physic, Dr. Philip (£3 5*s.*): Surgery, Mr. J. W. Dowden (£3 5*s.*); General Pathology, Dr. Russell (£3 5*s.*); Physiology (Institutes of Medicine) —— (£3 5*s.*); Materia Medica, &c., Dr. Craig and Dr. F. D. Boyd (£3 5*s.*); Clinical Medicine, Dr. Alexander Bruce, Royal Infirmary (£3 5*s.*); Clinical Surgery, Mr. Caird, Royal Infirmary (£3 5*s.*); Physics, Dr. Dawson Turner (£3 3*s.*); Biology, Miss Newbigin (£3 3*s.*); Vaccination, Dr. Buist (£1 1*s.*); Practical Gynæcology, Dr. Brewis (£2 2*s.*); Diseases of the Eye, Dr. W. G. Sym; Bacteriology, Dr. J. Taylor Grant; Fevers, City Hospital. Summer Session: Practical Anatomy, Dr. Ryland Whitaker (£2 2*s.*); Practical Chemistry, Mr. J. Kerr (£3 3*s.*); Materia Medica, &c., Dr. Craig (£3 3*s.*); Operative Surgery and Surgical Anatomy, Mr. J. W. Dowden (£3 3*s.*); Materia Medica and Therapeutics, Dr. Wm. Craig (£3 3*s.*); Medical Jurisprudence and Public Health, Dr. Aitchison Robertson and Dr. C. J. Lewis (£3 5*s.*); Clinical Medicine, Dr. Alexander Bruce; Clinical Surgery, Mr. Caird, Royal Infirmary (£3 5*s.*): Practical Physiology and Histology, Dr. Goodall (£3 3*s.*); Practical Pathology, Dr. Russell (£3 3*s.*); Biology, Miss Newbigin (£3 3*s.*); Physics, Dr. Dawson Turner (£3 3*s.*); Ophthalmology, Dr. A. H. H. Sinclair (£2 2*s.*); Insanity, Sir J. Batty Tuke and Dr. G. M. Robertson (£2 2*s.*); Practical Gynæcology, Dr. Brewis (£2 2*s.*); Practical Medicine, Dr. Philip and Dr. G. Lovell Gulland; Vaccination, Dr. Buist; Tropical Diseases, Major Marshall; Medical Electricity, Dr. Dawson Turner.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £115, payment of which is distributed over the period of study. There is no composition fee.

Further particulars regarding the school, also its calendar, may be had on application to Mr. R. N. Ramsay, the Secretary and Registrar, 27, Forrest-road, Edinburgh.

* Lectures, £3 5*s.*; Practical, £3 3*s.*; Analytical, £2 a month, or £5 for three months. † Also in Summer Session. ‡ Also in Winter Session. § Practical, £3 3*s.*; Analytical, £2 a month, or £5 for three months.

N.B.—Where two or more lecturers appear as teaching the same subjects their lectures are not conjoined, but each gives an independent course.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Dumbarton-road, Glasgow, W.—This medical school was founded in the year 1800. It has given 13 professors to the University of Glasgow. The following courses are given, which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions):—In winter: Anatomy, Professor A. M. Buchanan;

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
UNIVERSITY OF MANCHESTER—*continued.*	Hulme.	£35.	3 years.	Subjects: ENGLISH LANGUAGE and LITERATURE, HISTORY, GEOGRAPHY, and LATIN, GREEK FRENCH, or GERMAN (any two subjects).	
	James Gaskill.	£35.	2 years.	MATHEMATICS, MECHANICS, and CHEMISTRY.	
	Dora Muir.†	£25.	3 years.	Ditto.	
	Manchester Grammar School.*	£25.	3 years.	MATHEMATICS, ENGLISH ESSAY with CLASSICS and PHYSICAL SCIENCE in alternate years.	
	Kay-Shuttleworth.*	£30.	3 years.	Subjects as in James Gaskill Scholarships.	Pupils of Sedbergh, Giggleswick, or Burnley Grammar School.
	Theodores Exhibition.	£15.	1 year.	Subjects: FRENCH and GERMAN	Successful candidates are required to enter for a regular University course.
	Matriculation Entrance Scholarship	£30.	3 years.	Awarded on results of July Matriculation Examination.	
	Entrance Scholarships in Medicine.	£100.	......	One for proficiency in Arts. One for proficiency in Science.	No limit as to age. £60 set off against University fees and £40 against Infirmary fees.
	Platt Biological Scholarship.	£50.	1 year.	Awarded to candidate who shows the most promise of ability for prosecuting original research in ZOOLOGY and BOTANY.	To devote his time to research in Zoology or Botany.
	Robert Platt Physiological Scholarship.	£50.	2 years.	Subjects: PHYSIOLOGY and COMPARATIVE ANATOMY.	Open to Candidates whether or not previously students of the University.
	Dauntesey Medical Scholarships (two).	£35 each	1 year.	Subjects: ZOOLOGY, BOTANY, and CHEMISTRY.	These Scholarships are open to all students preparing for a Medical Course who shall not have attended Lectures or Laboratory Courses on Human Anatomy or Physiology, or a purely Medical or Surgical Course in the University or any other Medical School in the United Kingdom. Candidates must not be more than 25 years of age on October 1st of the year of competition. Scholars must immediately on election enter for a full course of medical studies.
	Robert Platt Exhibitions (two).	£15 each.	——	——	First and second year students in Physiology.
	Sidney Renshaw Exhibition.	£15.	——	——	Second year students in Physiology.
	Professor Tom Jones Exhibition in Anatomy.	£25.	......	......	First year students in Anatomy.
	Turner Scholarship.	£20.	——	Subjects: MEDICINE, PATHOLOGY (written and practical), OBSTETRICS, PRACTICAL SURGERY, OPHTHALMOLOGY, FORENSIC MEDICINE, and PUBLIC HEALTH.	Students who have completed a full course of medical study in the University are eligible only.
	John Henry Agnew Scholarship.	£30.	——	The Scholarship is awarded on the results of an Examination, partly written and partly clinical, on DISEASES OF CHILDREN, MEDICAL AND SURGICAL.	Open for competition annually to all students in the Medical Department who have pursued a regular course of medical study in the University extending over a period of not less than 4 years or more than 6, and who have attended the course of lectures on Diseases of Children.

---

† Open to women candidates only.

* Open to men candidates only.

The fee for each class is £2 2*s*., except Zoology and Botany, joint fee £3 3*s*., Anatomy, Winter Session, £4 4*s*., Pathology, £4 4*s*., Physics, £2 4*s*. 6*d*., Public Health Laboratory, £12 12*s*., and certain extra classes for which the fee is £1 1*s*. The hospital fee (including clinical lectures) is £21 for a perpetual ticket.

The classes in St. Mungo's College are now open to male and female students equally.

The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons amount to £65. Further particulars can be obtained from a syllabus which may be procured free on application to the Dean, 86, Castle-street, Glasgow.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is situated in University-avenue, close to the University and Western Infirmary. Lectures and Demonstrations are given on Chemistry, on Physics, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, on Pathology, on Medicine, and on the Eye. Some of the classes qualify for graduation and for Scotch diplomas.

Class Fees.—For each course of Lectures the fee is £2 2*s*., or in some cases £1 1*s*. There is no matriculation fee

Lecturers: Winter Session.—Physics: Dr. Muirhead, Monday, Wednesday, and Friday, at 2 P.M.; Chemistry: Mr. Gregory, Tuesday and Thursday at 3 P.M.; Anatomy: Dr. Wright Thomson, Tuesday, Wednesday, and Friday, at 4.15 P.M.; Surgery: Dr. Edington, at 12 noon; Midwifery: Dr. Balfour Marshall, Monday, Wednesday, and Friday, at 2 P.M.; Medicine: Dr. McKenzie, at 11 A.M.; Pathology: Dr. Jubb, Monday, Tuesday, Thursday, and Friday, at 3 P.M.; The Eye: Dr. Fergus, Monday and Thursday, at 4 P.M.

Summer Session.—Physics: Dr. Muirhead, Monday, Wednesday, and Friday, at 2 P.M.; Chemistry: Mr. Gregory, Tuesday and Thursday, at 3 P.M.; Anatomy: Dr. Wright Thomson, Tuesday and Friday, at 3.15 P.M.; Operative Surgery: Dr. Edington, Tuesday, Wednesday, and Friday, at 1 P.M.; Gynæcology: Dr. Balfour Marshall, at 2 P.M.; Medicine: Dr. McKenzie, at 8 A.M.; Pathology: Dr. Jubb, Monday, Tuesday, Thursday, and Friday, at 12 noon; Ophthalmology: Dr. Fergus, Monday and Thursday, at 11 A.M. and 3 P.M. Some of the above hours are liable to alteration.

QUEEN MARGARET COLLEGE, University of Glasgow.—Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs. John Elder. In 1890 a School of Medicine for women was added to its Arts Faculty. In 1892, when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs. Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only. The College then became the women's department of the University of Glasgow; its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The number of students enrolled in session 1906–1907 was 579, of whom about 60 were studying medicine and the rest arts or science. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University. 128 women have now taken the degree of M.B., C.M. or M.B., Ch.B. of the University of Glasgow. Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals. [illegible] ranted for the purpose by the Bella- [illegible] iversity Court was enabled to add to the College a large building for the study of Anatomy and Physiology, which was opened in October, 1895. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. A house of residence for the students of the College coming from a distance was opened by the Queen Margaret Hall Co., Limited, in October of 1894. The winter session commences on Oct. 17th.

Lecturers (other than University Professors).—Anatomy: Mr. T. H. Bryce. Chemistry: Mr. H. W. Bolam. Medicine: Dr. W. K. Hunter. Surgery: Mr. J. H. Pringle. Pathology: Dr. C. Workman. On the Eye: Dr. A. M. Ramsay.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the new medical buildings there are spacious and well-equipped laboratories and work-rooms for Anatomy, Physiology, Materia Medica, Pathology, Ophthalmology, Public Health, Medicine, Surgery, and Gynæcology. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 400 beds, including special wards for the Diseases of Women, Children, Eye, Ear and Throat, and Obstetric cases. There is in addition an Extern Obstetric Department. There were during last year 15,549 out-patients and 6411 home patients. The Royal Infirmary offers exceptional facilities for practical work to students. Appointments: Five qualified Resident Medical Assistants are appointed every six months and one non-resident. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica and in Practical Dentistry. Further information can be obtained from Dr. Fraser, Medical Superintendent.

ROYAL and DISTRICT ASYLUMS, Dundee.[*]—Physician Superintendent: Dr. William Tuach-Mackenzie. Lectures on Mental Diseases and clinical instruction in connexion with University College, Dundee (University of St. Andrews), are given during the Summer Session at University College and at the Royal and District Asylums by Dr. Tuach Mackenzie. The course consists of 12 Lectures and 14 Clinical Lectures and Demonstrations. There are two paid qualified Resident Assistants and two unpaid Resident Clinical Assistants. Senior Medical Assistant: Dr. H. C. Martin. Junior Medical Assistant: Dr. J. Morris. Clinical Assistants: Mr. D. Buist and Mr. J. Robertson.

ABERDEEN ROYAL INFIRMARY.—Contains 251 beds. Consulting Physician: Dr. P. Blaikie Smith. Physicians: Dr. Angus Fraser, Professor Finlay, and Dr. George M. Edmond. Assistant Physicians: Dr. John Gordon, Dr. A. H. Lister, and Dr. Ashley W. Mackintosh. Consulting Surgeons: Professor Alexander Ogston, Dr. J. C. O. Will, and Dr. J. Mackenzie Booth. Surgeons: Mr. J. S. Riddell, Mr. John Marnoch, and Mr. H. M. W. Gray. Assistant Surgeons: Dr. F. Kelly, Dr. Henry Peterkin, and Dr. Wallace Milne. Ophthalmic Surgeon: Dr. C. H. Usher. Gynæcologist: Professor W. Stephenson. Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. G. M. Duncan. Dental Surgeon: Dr. J. M. P. Crombie. Anæsthetist: Dr. J. J. Y. Dalgarno. Assistant Anæsthetists: Dr. W. R. Pirie and Dr. Thos. Fraser. Medical Electrician: Dr. J. R. Levack. Assistant Medical Electrician: Dr. Clifford T. Bell. Dermatologist and Lecturer on Diseases of the Skin: Dr. J. F. Christie. Medical Superintendent and Clinical Registrar: Dr. William Sinclair. Clerk and Treasurer and Factor for the Hospital Lands: Mr. A. Scott Finnie, 343, Union-street, Aberdeen. Medical session opens on Oct. 16th.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains, with hospital attached to main institution and Agricultural

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
UNIVERSITY OF LIVERPOOL—*continued.*	Johnston Colonial Fellowship (Pathology and Bacteriology).	£100.	1 year.	Vote of Faculty to Student after graduation.	Research in Pathology.
	John W. Garrett International Fellowship (Physiology and Pathology).	£100.	1 year.	Ditto.	Ditto.
	Stopford Taylor Fellowship (Dermatological Pathology).	£100.	1 year.	Ditto.	Ditto.
	Thelwall Thomas Fellowship (Surgical Pathology)	£100.	1 year.	Ditto.	Ditto.
	Ethel Boyce Fellowship in Gynæcological Pathology.	£100.	1 year.	Vote of Faculty to graduate.	Research.
	Bickersteth Scholarship Surgical Pathology.)	£50.	1 year.	Ditto.	Ditto
SHEFFIELD UNIVERSITY	Entrance.	£116.	....	Examination.	Must read for Degree in Medicine.
	Special (1907) (for Women only).	£100.	....	Special examination.	Ditto.
	Staff (Special 1907).	£50.	....	Ditto.	Ditto.
	Staff (Special 1907).	£50.	....	Ditto.	Ditto.
	Town Trust (two).	Each £50 per annum.	3 years.	Ditto.	Boys educated in Sheffield.
	Town Trust (one).	£50 per annum.	3 years.	Ditto.	Girls educated in Sheffield.
	Town Trust (two).	£60 per annum.	3 years.	Ditto.	Boys or girls educated in Sheffield.
	Kaye, in Anatomy and Physiology.	£22 10s.	1 year.	Ditto.	Students who have completed second Winter Session; native of Sheffield
	Town Trust Fellowship.	£75 per annum.	1 year.	The Senate considers each application.	Graduates of the University.
	Mechanics' Institute.	£50 per annum.	1 year, renewable to a second.	Ditto.	Post-graduate Scholarship.
	Frederick Clifford.	£50 per annum.	2 years.	Ditto.	Graduates of the University residing within 40 miles.
EDINBURGH UNIVERSITY	*Sibbald Bursaries (1 or 2 annually).	Each £30 per annum.	3 years.	Competitive Examination in Preliminary Subjects among *entrants.*	Continued Study.
	*Heriot Bursaries (7 for men and 1 for women annually).	Each £30 per annum.	3 years.	Ditto.	Ditto.
	*Thomson Bursaries (2 annually).	Each £25 per annum.	4 years.	Distinction in Medical Preliminary Examination.	Ditto.
	*Grierson Bursary. „ No. 1.	£20.	1 year.	Ditto	Ditto.
	*Crichton Bursaries (2 annually).	Each £50 per annum.	4 years.	Distinction in Medical Preliminary Examination, with extra subjects	Born in Scotland.
	* Mackie Bursary. „ No. 1.	£30 per annum.	2 years.	Vote of Faculty.	Pecuniary circumstances requiring assistance, &c.
	*Junior J. A. Carlyle Bursary.	£28.	1 year.	Distinction in Class Examinations in ANATOMY and CHEMISTRY.	
	* Coldstream Memorial Scholarship	£25 per annum.	5 years.	— —	Intention to become Medical Missionary, &c.
	* Vans Dunlop Scholarship. „ No. 1.	£100 per annum.	3 years.	First place in MEDICAL PRELIMINARY EXAMINATION.	Continued study.
	„ No. 2.	£100 per annum.	3 years.	Competitive Examination in CHEMISTRY, ANATOMY, and PHYSICS.	Ditto.
	„ No. 3.	£100 per annum.	3 years.	Ditto in BOTANY and ZOOLOGY.	Ditto.
	*Thomson Scholarship.	£40 per annum.	4 years.	Competitive Examinations in BOTANY, ZOOLOGY, and MECHANICS.	
	† Mackie Bursary. „ No. 2.	£30 per annum.	2 years.	Vote of Faculty.	Pecuniary circumstances requiring assistance, &c.
	† Grierson Bursary „ No. 2.	£20.	1 year.	Competitive Examination in CHEMISTRY, BOTANY, ZOOLOGY, and PHYSICS.	Continued study.
	†Senior J. A. Carlyle Bursary	£28.	1 year.	Distinction in Class Examinations in ANATOMY and PHYSIOLOGY.	Ditto.
	†Sibbald Scholarship.	£40 per annum.	3 years.	Competitive Examination in CHEMISTRY, BOTANY, ZOOLOGY, and PHYSICS.	Ditto.
	† Vans Dunlop Scholarship. „ No. 4.	£100 per annum.	3 years.	Competitive Examination in PHYSIOLOGY and SURGERY.	Ditto.
	† *Neil Arnott Prize.*	£37 10s.	— —	Distinction in NATURAL PHILOSOPHY in the M.A. Examination.	Ditto.

* For Students entering on or in their First Year.

† For Students entering on or in their Second Year.

of the Teeth: Mr. W. Taylor and Mr. Taylor, jun. Superintendent: Dr. J. Maxtone Thom.

Royal Hospital for Sick Children, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

Staff.—Consulting Physicians: Dr. J. Carmichael and Dr C. E. Underhill. Consulting Surgeons: Mr. T. Annandale and Mr. J. Bell. Consulting Surgeon Dentist: Mr. J. Smith. Pathologist: Mr. S. McDonald. Ordinary Physicians: Dr. G. H. M. Dunlop, Dr. J. Thomson, and Dr. J S. Fowler. Surgeon: Mr. H. J. Stiles. Ophthalmic Surgeon: Mr. G. A. Berry. Assistant Surgeon: Mr. E. W. S. Carmichael. Medical Electrician: Dr. J. W. Spence. Extra Physicians: Dr. W. B Drummond, Dr. J. W. Simpson and Dr. A. D. Fordyce. Anæsthetists: Mr. D. C. A. M'Allum and Dr. J. Politachi.

Eye, Ear, and Throat Infirmary of Edinburgh, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P.M. for out-door Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeons: Dr. Joseph Bell, Dr. Logan Turner (Ear, Nose, and Throat Department). Surgeons: Dr. William George Sym, Dr. Malcolm Farquharson, Dr. John Cumming, Dr. J. V. Paterson, Dr. E. M. Lithgow, and Dr. W. G. Porter. Dental Surgeon: Mr. G. W. Watson. Treasurer and Secretary: Mr. J. P. Watson, W.S., 13, Hill-street.

Glasgow Western Infirmary.—This hospital adjoins the University of Glasgow. Number of beds upwards of 520. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Fourteen resident assistants are appointed annually, without salary, from those who have completed their course. The fee for hospital attendance is £10 10*s.* and the fees for clinical instruction are £3 3*s.* for the Winter Session and £2 2*s.* for the Summer Session.

Staff.—Honorary Consulting Physician: Dr. G. P. Tennant. Honorary Consulting Surgeon: Dr. Alex. Patterson. Honorary Consulting Gynæcologist: Dr. W. L. Reid. Visiting Physicians: Sir T. McCall Anderson, Dr. Samson Gemmell, Dr. Ralph Stockman, and Dr. John Lindsay Steven. Visiting Surgeons: Sir Hector C. Cameron, Sir W. Macewen, Dr. J. C. Renton, Dr. George T. Beatson, C.B., Dr. T. K. Dalziel, and Dr. James H. Nicoll. Physicians for Diseases of Women: Dr. Murdoch Cameron and Dr. John M. Munro Kerr. Assistant Physicians: Dr. W. G. Dun, Dr. R. B. Ness, Dr. William MacLennan, and Dr. W. R. Jack. Assistant Surgeons: Dr. Duncan Macartney, Dr. Robert Kennedy, Dr. Alfred A. Young, Dr. G. B. Buchanan, Dr. John Morton, and Dr. G. H. Edington. Dispensary Physicians: Dr. James Carslaw, Dr. John S. M'Kendrick, Dr. Robert Fullarton, Dr. J. Campbell McClure, Dr. Frank Charteris, and Dr. A. B. Sloan. Dispensary Surgeons: Dr. Farquhar Macrae, Dr. Alex. MacLennan, Dr. Archd. Young, Dr. M. L. Taylor, Dr. W. W. Christie, and Dr. C. C. Cuthbert. Dispensary Physician for Diseases of Women: Dr. E. H L. Oliphant. Extra Dispensary Physicians: Dr. John Gracie, Dr. Leonard Findlay, Dr. John P. Duncan, and Dr. Murray Ross Taylor. Extra Dispensary Surgeons: Dr. A. H. Edwards, Dr. David Dickie, Dr R. B Carslaw, and Dr. John S. Barr. Extra Dispensary Physicians for Diseases of Women: Dr. G. N. Turner and Dr. S. Cameron. Dispensary Surgeon for Diseases of the Ear: Dr. Thomas Barr. Honorary Consulting Ophthalmic Surgeon: Dr. Thomas Reid. Dispensary Surgeon for Diseases of the Throat and Nose: Dr. J. Walker Downie. Pathologist: Dr. Robert Muir. Assistant Pathologists: Dr. J. H. Teacher and Dr. M. L. Taylor. Vaccinator: Dr. J. W. Nicol. Dental Surgeon: Mr. W. D. Woodburn, L.D.S. Superintendent: Dr. Donald J. Mackintosh, M.V.O. Matron: Miss H. Gregory Smith. Secretary and Treasurer: Henry Johnston, 87, Union-street. Assistant Secretary: J. Matheson Johnston, C.A.

Royal Hospital for Sick Children, Glasgow.—The Hospital at Garnethill was opened in December, 1882, and in June, 1903, a country branch consisting of two wards was opened at Drumchapel. The number of beds in the town hospital and country branch together is 100. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888, in West Graham-street. The whole institution is for non-infectious cases and is available to medical students for clinical instruction in the diseases peculiar to childhood. Classes are formed both at Hospital and Dispensary at the beginning of the University session in October. Students may be enrolled at any time. Fee £1 1*s.* per annum, admitting to both Hospital and Dispensary. Further particulars on applying to the House Surgeon, 45, Scott-street, Garnethill, Glasgow. Physicians: Dr. Samson Gemmell and Dr. George S. Middleton. Surgeons: Mr T. Kennedy Dalziel and Mr. R. H. Parry.

Glasgow Ophthalmic Institution, 126, West Regent-street (29 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 971; out- or dispensary patients, 9969. Operations on Wednesdays and Saturdays. Honorary Consulting Surgeon: Dr. D. N. Knox. Surgeon: Dr. A. Maitland Ramsay. Assistant Surgeons: Dr. John Rowan, Dr. H. Wright Thomson, and Dr. John Gilchrist. Pathologist: Dr. Mary Hannay. Bacteriologist: Dr. J. Campbell McClure. Electrician: Dr. John Gilchrist. House Surgeon: Dr. Agnes Picken. This institution is the Ophthalmic Department of the Royal Infirmary. A post-graduate course is given by Dr. Ramsay and assistants during September. Clinical instruction is given in the summer session to students of the University of Queen Margaret College and in winter to students of St. Mungo's College and to all who take the class.

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary. The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves. The average number of new patients for the last ten years has been 20,936·7, and the total number of cases treated in 1906 was 27,640. The Medical Staff is as follows:—Surgeons: Dr. Thomas S. Meighan, Dr. A. Freeland Fergus, Dr. Andrew Wilson, Dr. James Hinshelwood, Dr. Leslie Buchanan, and Dr. W. Ernest F. Thomson. Assistant Surgeons: Dr. A. Lewis M'Millan, Dr. Henry L. G. Leask, Dr. W. Cochrane Murray, Dr. Brownlow Riddell, Dr. Arthur J. Ballantyne, and Dr. A. A. Macfarlane. Pathologist: Dr. W. B. Inglis Pollock. House Surgeon: Dr. William Smellie. Assistant House Surgeon: Dr. John L. Stewart.

Regulations as to Attendance of Students.—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1*s.*, 12 months £2 2*s.* (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
GLASGOW UNIVERSITY.—	Two Highland Society Bursaries.	£25 each.	5 years.	Open 1907. Awarded on results of Preliminary Examination.	Open to medical students of Highland descent.
	Mackintosh Mental Science Bursary.	£31.	1 year.	— —	Open for competition to students of medicine of either sex attending the lectures on Insanity.
	Monteith Bursary.	£21.	2 years.	Vacant 1907. Examination in ANATOMY and PHYSIOLOGY.	Awarded on results of Second Professional Examination.
	Dr. Thos. Gibson Bursary.	£36.	4 years.	Vacant 1907. Competition by Students at the First Professional Examination.	Open to medical students preparing to be missionaries in connexion with the Church of Scotland.
	Coats Scholarship.	£80.	1 year.	Special Examination in PATHOLOGY Vacant 1907.	Open to Graduates in Medicine of not more than three years' standing. Holder to prosecute research in Pathology.
	John Macfarlane Bursary.	£40.	3 years.	Vacant 1908 Examination in ANATOMY, CHEMISTRY, and BOTANY.	Open to medical students entering on their Second Winter Session.
	Lorimer Bursary.	£24.	3 years.	Vacant 1907 Examination in ANATOMY, CHEMISTRY, and BOTANY.	Open to medical students entering on their Second Winter Session.
	One Armagh Bursary in Medicine.	£48.	3 years.	Competition by Students who are presenting themselves for the Final Examination for the degree of M.A. with Honours in MENTAL PHILOSOPHY.	Open to students of either sex who have taken the course of study for graduation in Arts and intend to study Medicine.
	One Armagh Bursary in Medicine.	£48.	2 years.	Competition by Students who are presenting themselves for the Final Examination for the degree of M.A. with Honours in CLASSICS	Ditto.
	Taylor Bursary.	£7.	4 years.	Appointment by the Senate	Open to students of either sex in any faculty.
	William Gardiner Bursary.	£14	2 years.	Vacant 1907. Competition in PHYSIOLOGY, CHEMISTRY, and PHYSICS of PROFESSIONAL EXAMINATIONS.	Open to medical students of either sex.
	Rainy Bursary.	£20.	2 years.	Vacant 1907. Examination in ANATOMY, PHYSIOLOGY, CHEMISTRY, BOTANY, and ZOOLOGY.	Open to medical students entering on their Fourth Winter Session.
	Two Paterson Bursaries.	£25 and £20.	4 years.	Vacant 1907. Examination in MATHEMATICS and DYNAMICS.	Open to medical students of First or Second Session.
	Brunton Memorial Prize.	£10.	1 year.	Awarded annually to the most distinguished Graduate in MEDICINE of the year	
	Dobbie Smith Gold Medal.	— —	— —	Awarded annually for the best essay on any subject within the limits of the science of BOTANY.	All matriculated students of 1905-6 or 1906-7 may be competitors.
	Two Arnott Prizes.	£25 and £15.	year.	Examination in PHYSIOLOGICAL PHYSICS &c.	
	Andrew and Bethia Stewart Bursary.	£50.	3 years.	Special Examination.	Candidates must be M.A. of Glasgow University.
	Weir Bursary.	£16.	1 year.	Awarded on result of Second and Third Professional Examinations.	
QUEEN'S COLLEGE, BELFAST	Ten Junior Scholarships for Matriculated Students, two for each of the five years' curriculum.	£20 each.	1 year.	Examination at the commencement of session	Open to matriculated Medical Students of either sex.
	Mackay Wilson Travelling Medical Scholarship.	£100.	1 year.	Appointed by the Council.	Holder must study for nine months in some foreign school of medicine approved by the Council.
ROYAL COLLEGE OF SURGEONS IN IRELAND, SCHOOLS OF SURGERY	Class Prizes.	£100.	— —	Proficiency in Class Examination.	Open to student of class.
	Stoney Gold Medal.	£3 15s.	......	For ANATOMY Class.	Open to students of class.
	Surgery Gold Medal.	£3 15s.	......	For PRACTICAL SURGERY Class.	Open to students of class.
	Carmichael Scholarship.	£15.	— —	Examination in ANATOMY, PHYSIOLOGY, HISTOLOGY, CHEMISTRY, MATERIA MEDICA, and PHARMACY, SURGERY, MEDICINE, PATHOLOGY, MIDWIFERY, and DISEASES OF WOMEN.	Open to students of the third year.
	Mayne Scholarship.	£23.	— —		Open to students of third and fourth year.
	Barker Bequest.	£31 10s	— —	For best DISSECTION.	Open to all medical students

H. R. Townsend, Dr. H. Corby, and Dr. T. G. Atkins. Ophthalmic Surgeon: Dr. A. W. Sandford. Extern Physicians: Dr. E. V. Cantillon and Dr. E. W. Allsom. Extern Surgeon: Dr. R. P. Crosbie. House Surgeon: Dr. J. P. Higgins. Dentist: Mr. T. C. Butterfield

Professors—Natural Philosophy: W. Bergin, M.A. Chemistry: A. E. Dixon, M.D. Anatomy: (vacant). Physiology: (vacant). Medicine: W. E. Ashley Cummins, M.D. Surgery: C. Yelverton Pearson, F.R.C.S. Materia Medica: John Dundon, M.D. Midwifery: H. Corby, M.D.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, *Galway.*—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years. The Council has power to award exhibitions for distinguished answering. Sessional prizes are offered in each subject. A Senior Scholarship in Anatomy, value £40, the holder of which may be appointed Demonstrator, is offered annually for competition tenable for one year by a student who shall have attended the Medical School of the College for at least two sessions and shall have obtained a Degree in Arts or Medicine or a Diploma in Medicine from a Licensing Body. Scholarship examinations are held at the commencement and those for Sessional Prizes at the close of each session. The Medical lectures are recognised by the Royal University of Ireland and the various Licensing Bodies in the United Kingdom. The College contains well lighted and ventilated dissecting room and anatomical lecture theatre; physiological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums; as well as a large natural history and geological museum and an extensive library in which students can read and from which they can borrow books. Clinical instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals. The following constitute the medical staff of the Galway Hospital.—*Physicians:* Professor Kinkead and Professor Lynham. Surgeons: Professor Pye, Professor Colahan, and Professor Brereton. *Gynæcologist:* Professor Kinkead. House Surgeon: Dr. Rouse. Instruction at the Galway Union and Fever Hospital is given by Professor Colahan and Dr. McDonogh. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a part is at the disposal of the College Athletic Union. A prospectus containing full information as to courses of lectures, scholarships, and fees for classes can be obtained on application to the Registrar, Queen's College, Galway.

Professors—Natural Philosophy: A. Anderson, LL.D. Chemistry: A. Senier, Ph D. Natural History; R. J. Anderson, M.D. Anatomy and Physiology: J. P. Pye, M D., D.Sc. Medicine: J I. Lynham, M D. Surgery: W. Westropp Brereton, L.R.C.S.I. Materia Medica: N. W. Colahan, M.D. Midwifery: R. J. Kinkead, M.D.

THE MEDICAL SCHOOL OF THE CATHOLIC UNIVERSITY, IRELAND, DUBLIN.—Founded in 1855, it is now the largest medical school in Ireland. It prepares students specially for the examinations of the Royal University and the Conjoint Colleges of Ireland and Edinburgh, but its lectures and practical courses are recognised by all the Licensing Bodies in Great Britain and Ireland. In addition to the ordinary medical examinations it prepares students for the D.P.H. and for the various higher University examinations in Pathology, Physiology, Chemistry, &c. One medical scholarship, six exhibitions, numerous gold and silver medals, and special prizes in anatomy, chemistry, and physics are offered annually for competition. The school opens for dissections on Oct. 1st; the winter lectures begin on Nov. 2nd. The Summer Session commences on April 1st.

Lecturers—Anatomy: Mr. E. P. McLoughlin, assisted by Mr. P. J. Fagan, Mr. G M. Keating, and Mr. T. T. O'Farrell. Physiology: Dr. D J. Coffey, M.A., M.B., and Dr. C. Coppinger, M.D., Emeritus Professor. Chemistry: Mr. Hugh Ryan, D.Sc., assisted by Mr. G. Ebrill, B.A. Surgery: Mr. J. S. M'Ardle, assisted by Mr. A. J. Blayney. Medicine: Sir Christopher Nixon, Bart. Midwifery: Dr. Alfred J. Smith. Pathology and Bacteriology: Dr. Edmond J. McWeeney. Physics: Mr. J. A. M'Clelland. Biology: Dr. George Sigerson. Practical Biology: Dr. Michael Curran. Ophthalmology: Dr. Louis Werner. Sanitary Science: Mr. Anthony Roche. Materia Medica: Dr. M. J. Dempsey. Medical Jurisprudence: Mr. Antony Roche. Practical Pharmacy: Mr. M. R. Hayes. Elementary Biology: Dr. D. J. Coffey. Elementary Physics: Mr. P. J. Fagan.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12s.; six months, £8 8s. Summer, three months, £5 5s.

Staff.—Physicians: Dr. James Little, Dr. Wallace Beatty, and *Dr.* H. T. Bewley. *Surgeons:* Mr. F. T. Heuston and Mr. T. E. Gordon. Obstetric Surgeon: Sir W. J. Smyly. Ophthalmic Surgeon: Sir H. R. Swanzy. Throat Surgeon: Dr. S. Horace Law. Pathologists and Bacteriologists: Dr. J. Alfred Scott and Dr. W. Geoffrey Harvey. Dental Surgeons: Dr. Theodore Stack and Mr. John Stanton. Assistant Physician: Dr. G. Peacocke. Assistant Surgeon: Dr. K. E. Levison-Gower Gunn. House Surgeons: Dr. J. *Allman Powell and Dr. Gordon Wright.*

Two resident surgeons are elected yearly and three resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Dermatology will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology, Gynæcology, and Dermatology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Mr. F. T. *Heuston.*

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland; nearly 18,000 cases are treated annually, either as *intern or extern patients. Lectures* are delivered, practical instruction given, and gynæcological operations are performed in the theatres daily. There is a *general dispensary* held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynæcology is given. This is the largest dispensary of its kind in Dublin. There is no extra charge for attendance at this dispensary. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. The resident quarters have been much enlarged. A billiard table has been erected for the use of students. Fees: Extern pupils for full course of six months, £8 8s.; three months, £4 4s. Intern pupils, one month, £4 4s.; each consecutive month, £3 3s.; six months, £18 18s.; board and lodging in the hospital, 18s. per week. Lady students' intern, one month, £5 5s.; each consecutive month. £4 4s. Registration fee, in advance, 10s. 6d. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the hospital.

Staff.—Consulting Physicians: Sir John Banks, Sir John W. Moore, and Dr. J. M. Redmond. Consulting Surgeons: Dr. F. T. Heuston and Dr. F. W. Kidd. Pathologist: Dr. E. J. McWeeney. Pathological Analyst: Sir C. A. Cameron. Master: Dr. T. G. Stevens. Assistant Masters: Dr. Ronald S. Orbell and Dr. Thomas W. Conway. Registrar: Fred. A. Heney.

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Classes for clinical instruction both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for students commencing their hospital studies will be held in the wards during the months of October, November, and December. They will embrace the elements of Medicine and Surgery, including note-taking. The surgical operating theatre,

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

DURING the year considerable changes have been made in the regulations for the Royal Army Medical Corps and Indian Medical Service. The conditions of service in the medical department of the Royal Navy remain much the same as they were at the date of the issue of the Students' Number in 1906. In our issue of Nov. 17th last we commented on the introductory address delivered by Sir Lambert Ormsby, the senior surgeon to the Meath Hospital, Dublin, and a past President of the Royal College of Surgeons in Ireland. Sir Lambert Ormsby appended to his address a forcible indictment of the present conditions in the medical service of the Royal Navy. We pointed out in our issue that, while we must agree that there are defects in the service, things are not so bad as Sir Lambert Ormsby would have us believe. In the matter of foreign service and of service ashore there is room still for considerable reform—many of the shore appointments are made not for conspicuous ability but in consequence of conspicuous influence. A fair and proper roster for foreign service should certainly be in force. The control of the sick-berth staff on shore should be entirely in the hands of the principal medical officer, who should have precisely the same power when serving in a naval medical establishment on shore as is enjoyed by his military *confrères* in the Royal Army Medical Corps. It is ridiculous that a senior medical officer should have no power to punish his subordinates in hospitals and sick quarters. In the matter of "medical guard," it should be laid down in the King's Regulations that medical guard is to be recognised by the captains and commanding officers of all ships, thus putting it beyond the capricious exercise of executive authority. In conducting medical surveys which are held for purely medical purposes an Inspector-General should certainly not be required to sit, as he is at present, under the presidency of a captain or commander of the executive branch. It is the general desire of the service that when a medical officer is tried by court-martial some of the members constituting the court should be medical officers of high rank. In the matter of salutes, of boats in harbour, of honours, and the appropriation of cabins there is much to remedy before contentment can reign in the Medical Service. Naval medical officers are subjected to many petty annoyances which could be remedied and prevented, we believe, without any loss of discipline or efficiency. Sir Lambert Ormsby's advice to the Dublin students is to "avoid the Naval Medical Service for the present, which will compel the authorities, in order to get good men, to rectify the glaring defects by placing the naval medical officer in his proper position and giving him in all fairness equal advantages, socially and professionally, with his less scientifically educated executive brother officer." Some of the grievances pointed out by Sir Lambert Ormsby are real defects, and we hope to see changes introduced during the coming year which will make the position of the naval medical officer a more comfortable one. A few weeks ago the Lords Commissioners of the Admiralty issued an order that naval medical officers are not to receive fees for evidence at coroners' inquests or for performing post-mortem examinations on a coroner's order, and that they are to consider this part of their duties; this order is manifestly unfair in the case of a man on half-pay.

In the Army Orders for February, 1907, the terms of a Royal Warrant, dated Jan. 9th, are set forth. The Warrant amends that of March 19th, 1906, in accordance with new provisions and with a view to giving a practical and working effect to them. It deals with promotion, rates of pay, half and retired pay, and the new arrangements relating to the administrative staff, with the apparent object of simplifying and confirming the new system of army administration which has grown up and been practically established. It contains the new regulations connected with a new and very extended system of instruction in sanitation throughout the army. In the early part of this year the Secretary of State for War approved of the amalgamation of the Army Medical Advisory Board and the Army Hospital and Sanitary Committee. The reconstituted Army Medical Service Advisory Board is composed of the Director-General, Army Medical Service, chairman; the Deputy Director-General, vice-chairman; Colonel D. Bruce (as expert in tropical diseases); Colonel Scott-Moncrieff, C.I.E., R.E., assistant director of fortifications and works; Lieutenant-Colonel C. H. Melville (as expert in sanitation); and the following civilian members: Sir F. Treves, civilian surgeon; Professor J. Rose Bradford (University College, London), civilian physician; Dr. Louis Parkes (consulting sanitary adviser to the Office of Works), civilian sanitary expert; Dr. M. S. Pembrey (Guy's Hospital), civilian physiologist; and Sir Charles A. Cameron, representing sanitation in Ireland; with Surgeon-General A. M. Branfoot, as representative of the India Office. Lieutenant-Colonel C. H. Melville is the secretary. The Advisory Board has been made more distinctly advisory in its functions. The committee (or board) will carry out such scientific investigations as they may deem requisite for the elucidation of points referred to them. For these purposes they will have power to co opt members of the staff of the Royal Army Medical College. The new conditions have added to the powers and responsibilities of the Advisory Board and will enlarge its sphere of usefulness. The changes should also have the effect of putting the Medical Service in a more defined and independent position and one more worthy of the responsible scientific functions which it is called upon to discharge.

Candidates for the Royal Army Medical Corps must note that in future there can be no certainty of their obtaining a higher rank in the army than that of Major, since the number of Lieutenant Colonels is now limited.

We note with much satisfaction that in the printed conditions of service in the Indian Medical Service the pay and prospects in civil employment are set forth at greater length than was formerly the custom. We are also glad to see that the date of an officer's first commission has been altered in accordance with our suggestions.

ROYAL NAVY MEDICAL SERVICE.

REGULATIONS FOR THE ENTRY OF CANDIDATES FOR COMMISSIONS IN THE MEDICAL DEPARTMENT OF THE ROYAL NAVY.

Every candidate for admission into the Medical Department of the Royal Navy must be not under 21 nor over 28 years of age on the day of the commencement of the competitive examination. He must produce an extract from the register of the date of his birth; or, in default, a declaration made before a magistrate, from one of his parents or other near relative, stating the date of birth. He must also produce a certificate of moral character, up to date, and a recommendation signed by a clergyman or magistrate, to whom he has been for some years personally known, or by the president or senior professor of the college at which he was educated.

He must be registered under the Medical Act in force, as qualified to practise medicine and surgery in Great Britain and Ireland.

He must declare (1) his age and date and place of birth; (2) that he is of pure European descent and the son either of natural-born British subjects or of parents naturalised in the United Kingdom; (3) that he labours under no mental or constitutional disease or weakness, nor any other imperfection or disability which may interfere with the most efficient discharge of the duties of a medical officer in any climate; (4) that he is ready to engage for general service at home or abroad, as required; (5) whether he holds, or has held, any commission or appointment in the public services; and (6) that he is registered under the Medical Act in force as duly qualified professionally, and what diplomas, &c., he holds.[1]

He must be free from organic or other diseases, and his physical fitness will be determined by a Board of Medical Officers, who are to certify that his vision comes up to the required standard, which will be ascertained by the use of Snellen's Test Types. The certificates of registration, character, and birth, must accompany the declaration, which is to be filled up and returned as soon as possible, addressed as above.

The examination will consist of two parts as follows:—(1) Compulsory subjects; (2) voluntary subjects. The admission of candidates will be determined solely by the number of marks gained in the compulsory subjects. Successful candidates who qualify in voluntary subjects will have the marks so obtained added to those gained in the compulsory subjects, and their position on the list will be determined by the total of marks for both compulsory and voluntary subjects.

Candidates will be examined by the Examining Board in the following compulsory subjects and the highest number of marks attainable will be distributed as follows (a fee of £1 will have to be paid by each candidate to entitle him to take part in the competition): (*a*) medicine, materia medica, therapeutics and general hygiene, 1200 marks; (*b*) surgery and surgical anatomy, 1200 marks. The examination in medicine and surgery will be in part practical and will include, beyond papers, the examination of patients, the examination of pathological specimens, a knowledge of bacteriology, the performance of operations on the dead body, and the application of surgical apparatus. The attention of candidates is especially drawn to the importance of the section of Operative Surgery, as a competent knowledge in this subject is essential in order to qualify for a commission. No candidate shall be considered eligible who shall not have obtained at least *one-third* of the maximum marks in each of the above *compulsory subjects*.

Candidates may be examined in the following voluntary subjects, for which the maximum number of marks obtainable will be—Natural Sciences: chemistry (300); physiology (300); zoology (300); botany (300); and geology and physical geography (300). No candidate will be allowed to present himself for examination in more than two of these subjects. French and German (300 each), 600 marks. A number less than one-third of the marks obtainable in each of these *voluntary subjects* will not be allowed to count in favour of the candidate who has qualified in the *compulsory subjects*. The knowledge

---

[1] If any doubt should arise on this question the burden of clear proof that he is qualified will rest upon the candidate himself.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY.

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
LONDON UNIVERSITY*	No. 1.	£40 per annum.	1 year.	Awarded to the most meritorious of those candidates, whether internal or external, who, having passed the whole Intermediate Examination in Medicine at one time, have been awarded marks of distinction in (1) ANATOMY, or (2) PHYSIOLOGY, or (3) PHARMACOLOGY.	No candidate will be allowed to receive the income of more than one scholarship at the same time.
	No. 2.	£40 per annum.	1 year.		
	No. 3.	£30 per annum.	1 year.		
SOCIETY OF APOTHECARIES OF LONDON	Gillson.	£90 per annum.	1 year.	Open to Licentiates of the Society, or to candidates for the Society's Diploma who obtain such Diploma within six months of their election to the scholarship.	Candidates must be under 35 years of age.
ST. BARTHOLOMEW'S MEDICAL SCHOOL	Entrance Scholarships. No. 1.	£75.	—	Open Competitive Examination in not more than three nor fewer than two of CHEMISTRY, PHYSICS, ZOOLOGY, BOTANY, PHYSIOLOGY, ANATOMY.	Full or University Course at St. Bartholomew's Hospital.
	" No. 2.	£75.	—		Ditto.
	" No. 3	£150.	—	Open Competitive Examination in not fewer than three of the following:—CHEMISTRY, PHYSICS, BOTANY, ZOOLOGY, PHYSIOLOGY.	Full Course at St. Bartholomew's Hospital.
	Preliminary Scientific Exhibition.	£50.	—		Ditto.
	Entrance Scholarship in Arts	£100.	—	Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, or FRENCH, or GERMAN.	Ditto.
	Jeaffreson Exhibition.	£20.	....	Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, or FRENCH, or GERMAN.	Ditto.
	Shuter Scholarship.	£50.	—	Competitive Examination among Cambridge Graduates in ANATOMY and PHYSIOLOGY	Ditto.
	Junior Scholarships. " No. 1.	£30.	—	Competitive Examination among Students in ANATOMY and BIOLOGY.	Study at St. Bartholomew's Hospital.
	" No. 2.	£20.	—	Ditto.	Ditto.
	" No. 3.	£25.	—	Competitive Examination in CHEMISTRY, PHYSICS, and HISTOLOGY.	Ditto.
	" No. 4.	£15.	—	Ditto.	Ditto.
	Senior Scholarship.	£50.	—	Competitive Examination among Students in ANATOMY, PHYSIOLOGY, and CHEMISTRY.	Ditto.
	Kirkes Scholarship.	£30 and Medal.	—	Competitive Examination among Students in CLINICAL MEDICINE.	Ditto.
	Brackenbury Scholarships. " No. 1.	£39.	—	Competitive Examination among Students in MEDICINE.	Ditto.
	" No. 2.	£39.	—	Competitive Examination among Students in SURGERY.	Ditto.
	Lawrence Scholarship.	£45 and Medal.	—	Competitive Examination among Students in SURGERY, MEDICINE, and MIDWIFERY.	Ditto.
	Sir Geo. Burrows Prize.	£10.	—	Competitive Examination in PATHOLOGY among Students.	Ditto.
	Skynner Prize.	13 guineas.	—	Competitive Examination in REGIONAL and MORBID ANATOMY among Students.	Ditto.
	Matthews Duncan Medal and Prize.	£20.	—	Competitive Examination among Students in MIDWIFERY and GYNÆCOLOGY.	Ditto.
	Luther Holden Research Scholarship in Surgery. (And other Prizes and Medals of less value.)	£105.	—	By Election.	Ditto.
CHARING CROSS HOSPITAL AND COLLEGE	Entrance Scholarships, open to students at the commencement of curriculum. Livingstone.	100 guineas.	—	The Livingstone and Huxley Scholarships are awarded annually at the commencement of each Winter Session, after a competitive examination in the following groups of subjects:—(1) ENGLISH, including LANGUAGE, HISTORY, and GEOGRAPHY; (2) LATIN and any one of the following three languages—GREEK, FRENCH, and GERMAN; (3) MATHEMATICS, including ARITHMETIC, ALGEBRA, and GEOMETRY; and MECHANICS, including STATICS and DYNAMICS; (4) INORGANIC CHEMISTRY and EXPERIMENTAL PHYSICS, including ACOUSTICS, HEAT, MAGNETISM, ELECTRICITY, and OPTICS; and (5) ANIMAL and VEGETABLE BIOLOGY. No Candidate may offer himself for examination in more than three of the above groups of subjects, the selection of the groups being left entirely to the Candidate.	Open to all general students.
	—	60 "	—		Open to all general students.
	Huxley.	55 "	—		For sons of medical men.
	—	40 "	—		Open to all general students.
	—		—		For dental students.

Inspector-General	1 18 0	693 10 0

Candidates will do well to notice that the regulations issued to applicants do not put any limit on the amount of half-pay service which they may be compelled to undergo.

Retirement.

Compulsory retirement will be as follows:—

Inspector and Deputy Inspector-General of Hospitals and Fleets.	At the age of 60, or at any age, if he has had three years' non-employment in any one rank, or after four years' continuous non-employment in any two ranks combined. Except that if in any particular case the Lords Commissioners of the Admiralty may consider that the interests of the public service will be materially advanced by the further retention of an Inspector-General of Hospitals and Fleets on the active list, the age for the retirement of such Inspector-General may be extended to 62.	To be retired irrespective of age if found physically unfit for service.
Fleet Surgeon, Staff Surgeon, and Surgeon.	At the age of 55, or at any age, if he has had three years' non-employment in any one rank, or after four years' continuous non-employment in any two ranks combined.	

The special attention of candidates is directed to the following rules under which officers are allowed to withdraw from the service after four years' full pay service in the Royal Navy, with the advantage of joining the Reserve of Naval Medical Officers:—

After four years' service in the Royal Navy, an officer, if he wishes, may pass from active service to the Reserve of Naval Medical Officers, when he will reap the following advantages:—

(1) He will be granted a gratuity of £500 on passing into the Reserve.

(2) His name will be retained in the Navy List; he will retain his naval rank and be entitled to wear his naval uniform under the regulations applying to officers on the retired and reserved lists of His Majesty's Navy.

(3) If he agree to remain in the Reserve for four years he will receive a retaining fee of £25 per annum. If at the expiration of this period he agree to remain in the Reserve for a further period of four years he will continue to receive the same retaining fee.

Should an officer prefer it, however, he may simply enter the Reserve for a period not exceeding eight years, with power to give six months' notice of his intention to resign his position at any time (in which case he will receive no retaining fee). He may also adopt this method of Reserve service after the expiration of four years served under the conditions referred to in (3), by renouncing his retaining fee for his last four years' service in the Reserve.

No officer will be allowed to remain in the Reserve for a longer period than eight years.

Officers of the Reserve will be liable to serve in the Royal Navy in time of war or emergency. When called up for such service they will receive the rate of pay—viz., 17*s.* a day and allowances—to which they would have been entitled after four years' service on the active list.

Voluntary retirement and withdrawal will be allowed as follows. (*a*) Every officer will have the option, subject to their Lordships' approval, of retiring after 20 years' full-pay service on the scale of retired pay provided in Paragraph 16, or with a gratuity on the scale provided in that paragraph if not eligible for retired pay. (*b*) At the expiration of four, eight, 12, or 16 years' full-pay service every officer will be permitted, subject to their Lordships' approval, to withdraw from the Naval Service, receiving a gratuity on the scale laid down in Paragraph 16. The name of an officer so withdrawing will be removed from the lists of the Navy, with which all connexion will then be severed, except in the case of officers who withdraw after four years who are liable to serve in the Reserve. (*c*) Voluntary retirement and withdrawal at the discretion of their Lordships will be allowed, as a rule, only when an officer is unemployed or serving at home. Under very special circumstances, however, it may be permitted in the case of an officer serving abroad, provided he pays his passage home, and, if necessary, that of his successor. (*d*) Applications from officers to retire or withdraw or resign their commissions will receive every consideration, but no officer will, as a rule, be permitted to resign under three years from the date of entry.* In order that arrangements may, as far as possible, be made for the relief of officers who may wish to withdraw on a gratuity it is desirable that six months' notice of their wish should be forwarded for the consideration of their lordships.

* The Admiralty reserve to themselves power to remove any officer from the list for misconduct.

Gratuities and retired pay will be awarded on retirement and withdrawal on the under-mentioned scale (Paragraph 16):—

Rank.	Gratuities.	Daily.	Yearly.
Surgeon, Staff Surgeon, and Fleet Surgeon—	£ s. d.	£ s. d.	£ s. d.
After 4 years' full-pay service	500 0 0	—	—
After 8 years' full-pay service (including service allowed by Para. 4 (*f*)) ...	1000 0 0	—	—
After 12 years' full-pay service (including service allowed by Para. 4 (*f*)) ...	1500 0 0	—	—
After 16 years' full-pay service (including service allowed by Para. 4 (*f*)) ...	2250 0 0	—	—
Fleet Surgeon—			
After 20 years' service (including proportion of half-pay time)	—	*1 0 0	36 0 0
After 24 years' service (including proportion of half-pay time)	—	*1 2	410 12 6
After 27 years' service (including proportion of half-pay time)	—	*1 5 0	456 5 0
After 30 years' service (including proportion of half-pay time)	—	*1 10 0	547 10 0
Deputy Inspector-General ...	—	1 15 0	638 15 0
Inspector-General	—	2 0 0	730 0 0

* To obtain this rate an officer must hold the commission of Fleet Surgeon.

An officer retired with less than 20 years' service on account of disability, contracted in and attributable to the Service, will receive the half pay of his rank, or, with the consent of their Lordships, a gratuity on the scales given in Paragraphs 16 and 18 (*b*), but such officer will not be entitled to receive any special compensation for the disability in addition to the gratuity as above (Paragraph 17).[2]

An officer retired with less than 20 years' service on account of disability, contracted in but not attributable to the Service, will receive—(*a*) if he has over eight years' full-pay service, either a gratuity on the scale given in Paragraph 16 or half-pay according as their Lordships think fit; (*b*) if he has less than eight years' full pay service, such gratuity as their Lordships think fit, not exceeding the rate of £125 for each year of full-pay service (Paragraph 18). In circumstances other than those specified in Paragraphs 17 and 18, and other than misconduct, neglect of duty, &c., an officer retired with less than 20 years' service will not be allowed half pay or retired pay, but will receive a gratuity on the scale laid down in Paragraph 16 if he has eight years' full pay service, and on that provided in Paragraph 18 (*b*) should his full-pay service not amount to eight years. The power vested in their Lordships of granting reduced rates of half pay and retired pay in cases of misconduct is extended to the award of gratuities on retirement, and the gratuity awarded will be reduced to such an amount as is thought fit. An officer retiring after 20 years' full pay service will be eligible, if recommended by the Medical Director-General for distinguished or meritorious service, to receive a step of honorary rank, such step to be awarded at their Lordships' discretion, and not to confer any claim to increase of retired pay or of widow's pension. All retired officers will be liable, till the age of 55, to serve in time of declared national emergency, in a rank not lower than that held on retirement. This liability does not exist in cases of officers who withdraw from the Naval Service receiving a gratuity after 8, 12, or 16 years' full pay service. Retired officers will receive special consideration as regards appointments on shore connected with the Admiralty now filled by civilians.

Widow's Pension.

When an officer retires or withdraws *on a gratuity* his widow and children will have no claim to pension or compassionate allowance. Officers serving in the reserve who during re-employment are injured on duty, or lose their lives from causes attributable to the service, come under the same regulations as regards compensation for themselves, or pensions and compassionate allowances for their widows and children, as officers of the same rank on the permanent Active List.

Miscellaneous.

A special cabin will be appropriated to the Fleet or Staff Surgeon or the Surgeon in charge of the medical duties in each ship. Special regulations have been made as regards the mess expenses of medical officers appointed to the several divisions of Royal Marines for limited periods. Every medical officer will be required to undergo a post-graduate course of three months' duration at a Metropolitan Hospital once in every eight years (should the exigencies of the Service permit), and this as far as possible during his Surgeon's, Staff Surgeon's, and Fleet Surgeon's period of service. While carrying out this course the medical officer will be borne on a ship's books for full pay and will be granted lodging and provision allowances and travelling expenses as for service under the Regulations to and from his home or port; the fees for each course (not exceeding £25) will be paid by the Admiralty on

---

[2] If the health of a surgeon breaks down before he completes 20 years' service, even if his disability be contracted in the Service or be due to climatic causes, he is liable at once to be placed on the retired list, receiving only a gratuity. This point should be well noted, as it is a most unjust one.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

Institution.	Title of Scholarship, &c.	Annual or Total Value.	How long Tenable.	How obtainable.	Conditions attached to Tenure.
GUY'S HOSPITAL—*continued.*	Entrance Scholarships. No. 2.	£50.	— —	Under twenty-five years of age, ditto.	Course at Guy's Hospital.

	Sambrooke Registrarship. No. 1.	£50.	— —	Competitive Examination among Matriculated Medical Students who have filled certain appointments at hospitals.	
	" No. 2.	50.	— —	Ditto.	

tests without hesitation in ordinary daylight. (N.B.—Snellen's test types will be used for determining the acuteness of vision.) Squint, or any morbid conditions, subject to the risk of aggravation or recurrence in either eye, will cause the rejection of a candidate. (1) Inability to distinguish the principal colours will not be regarded as a cause for rejection, but the fact will be noted in the report, and the candidate will be informed. (2) The degree of acuteness of vision of all candidates for commissions (including preliminary examinations) will be entered in their reports in the following manner:—

Sufficient	Right eye	...	V =
	Left eye	...	V =
Defective	Right eye	...	V =
	Left eye	...	V =

No relaxation of the standard of vision will ever be allowed.

The following additional points will then be observed. (b) That his hearing is good. (c) That his speech is without impediment. (d) That his teeth are in good order. Loss or decay of the teeth will be considered a disqualification Decayed teeth if well filled will be considered as sound. (e) That his chest is well formed and that his heart and lungs are sound. (f) That he is not ruptured. (g) That he does not suffer from varicocele or varicose veins in a severe degree, or other disease likely to cause inefficiency. A slight defect if successfully cured by operation is not a disqualification. A definition of severe varicocele may be obtained from the Director-General Army Medical Service, War Office, Whitehall, S.W. (h) That his limbs are well formed and developed. (i) That there is free and perfect motion of all the joints. (j) That his feet and toes are well formed. (k) That he does not suffer from any inveterate skin disease. (l) That he has no congenital malformation or defect. (m) That he does not bear traces of previous acute or chronic disease pointing to an impaired constitution. In any doubtful case the Board should further state: (n) Whether he is in their opinion of pure European descent. If a candidate be pronounced physically fit for service at home and abroad he will be eligible to present himself at the next entrance examination which will be held twice in the year, usually in January and July.

The Army Council reserves the right of rejecting any candidate who may show a deficiency in his general education.

An entrance fee of £1 is required from each candidate admitted to the examination and is payable at the conclusion of his physical examination, if pronounced fit.

Candidates who have been specially employed in consequence o a national emergency, either as an officer or in a position usually filled by an officer, will be allowed to reckon such service towards retired pay and gratuity, and if over the regulated limit of age at the date of commencement of the competitive examination shall be permitted to deduct from their actual age any period of that service, if such reduction will bring them within the age limit. The duration of service is to be reckoned from the date on which the candidate commenced such service, except in the case of candidates who have served for two or more periods at short intervals. In such cases the total period of service to be considered in granting marks at the entrance examination shall be specially determined.

A candidate successful at the entrance examination will be appointed a Lieutenant on probation and will be required to pass through such courses of instruction as the Army Council shall decide and, after passing the examinations in the subjects taught and satisfying the Director-General that he possesses the necessary skill, knowledge, and character for permanent appointment to the Royal Army Medical Corps, his commission as Lieutenant will be confirmed. The commission shall bear the date of passing the entrance examination.

Before the commission of a Lieutenant on probation is confirmed he must be registered under the Medical Acts in force in the United Kingdom at the time of his appointment.

The precedence of Lieutenants among each other shall be in order of merit as determined by the combined results of the entrance examination and the examinations undergone while on probation, except that the position on the list of a lieutenant on probation, seconded to hold a resident appointment in a recognised civil hospital shall be determined by the place he has gained at the entrance examination. A lieutenant so seconded will be required, at the conclusion of his hospital appointment, to attend the course of instruction at the Royal Army Medical College; but the subsequent examinations will be of a qualifying character and will not influence his position on the seniority list of the Corps.

Lieutenants when appointed on probation will receive instructions as to the provision of uniform.

EXAMINATIONS.

Subjects for the Entrance Examination.

Candidates will be examined by the examining board in medicine and surgery. The examination will be of a clinical and practical character, partly written and partly oral, marks being allotted under the following scheme.

Medicine (written).

	Maximum marks.
A. Examination and report upon a medical case	125
B. Commentary upon a case in medicine	100
(Two periods of 45 minutes – total, one a half hours —for A and one and a half hours for B.)	

Medicine (oral).

A. Clinical cases	100
B. Medical pathology	75
(Ten minutes to examine case and ten minutes *viva voce*—total, 20 minutes—for A; 30 minutes to examine specimens and ten minutes *viva voce* —total, 40 minutes—for B.)	

Surgery (written).

A. Examination and report upon a surgical case	100
B. Commentary upon a case in surgery	125
(Two periods of 45 minutes—total, one and a half hours—for A and one and a half hours for B.)	

Surgery (oral).

A. Clinical surgery and pathology (including diseases of the eye)	
B. Operative surgery and bandaging (including surgical instruments and appliances)	
(Ten minutes to examine case and ten minutes *viva voce*—total, 20 minutes—for A, and about 30 minutes for B.)	

Total marks	

The following headings are published as a guide to canc drawing up their reports on cases:—(a) A brief history of th given by the patient, including such points only (if any) in t or personal history as have a distinct bearing upon the prese or incapacity. (b) A detailed account of the subjective symp physical signs elicited by the candidate's personal examinatio patient, noting the absence of any which might be expect present in a similar case. (c) Where there is any reasonat in the mind of the candidate as to an exact diagnosis give the alternatives, with his reasons for making the (d) A commentary upon the case as a whole, pointing symptoms which may be considered typical and those which a be unusual or only accidental complications. (e) Suggestions as ment, both immediate and possibly necessary at a later date forecast of the progress and probable termination of the case.

Similarly the commentary on the report of a case submitte candidate should discuss: (a) The family and personal hist other conditions preceding the development of the cc described. (b) The relative significance of the physical symptoms, other indications of disease noted, and the clinical aspects of the case. (c) The diagnosis, with reas selection of the most probable, when a positive diagnosis can attained. (d) The treatment, dietetic, medicinal, operative, cluding a criticism of the plan adopted, and alternative sche treatment in case of disagreement. (e) The morbid appearanc an account of the post-mortem examination (if any).

The examination will be held in London and will o about four days.

The appointments announced for the competition wi filled up from the list of qualified candidates arranged i order of merit, as determined by the total number of n each has obtained. Having gained a place in this entr examination the successful candidates will be ordere proceed to the Royal Army Medical College for instructic recruiting duties, at the termination of which they will the Royal Army Medical Corps School of Instructior Aldershot for a two months' course in the technical du of the corps and at the end of the course will be examinec the subjects taught. The maximum number of ma obtainable at this examination will be 100. On complet of the above course lieutenants on probation will rejoin Royal Army Medical College to undergo two months' instr tion in Hygiene, Pathology, Tropical Medicine, Milit Surgery, and Military Medical Administration, after whi they will be examined in these subjects. The maximu number of marks obtainable at this examination will be 7(At the present time the professors at the Royal Arn Medical College are Major C. G. Spencer, M.B., F.R.C.S in the department of military surgery; Lieutenant-Colon Robert J. S. Simpson, M.B., C.M.G., in the department military medicine; Major W. B. Leishman, M.B., in th department of pathology; and Lieutenant-Colonel A. M Davies in that of hygiene, Major W. S. Harrison, M.B. and Major C. E. P. Fowler, F.R.C.S., both of th Royal Army Medical Corps, being the respective assistan professors. Colonel H. R. James, F.R.C.S., the commandan of the Royal Army Medical College, instructs in hospital anc corps administration, in the duties of officers on transports, and in the examination of recruits, and Brevet-Colonel F. J. Lambkin lectures on Syphilology. The course of hygiene has hitherto comprised the examinations of water and air, the general principles of diet with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the consideration of the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The pathological course has up to the present time included bacteriology and demonstrations in physiological chemistry. The surgical course consists of lectures and demonstrations in military surgery and lectures on errors of refraction from a military point of view. On completion of the above course Lieutenants on probation will be ordered to proceed to the depôt of the Royal Army Medical Corps at Aldershot for a three months' course of instruction in the technical duties of the corps, and at the end of the course will be examined in the subjects taught. A Lieutenant on probation who fails to qualify in either of these examinations will be allowed a second trial, and,

to qualify, may have been debarred from further opportunity of qualifying, may be provisionally promoted. If, however, he fails to qualify on the first available opportunity his promotion shall be cancelled and he shall be retired from the service. An officer shall reckon towards his promotion any time, not exceeding one year, during which he may have been on half-pay on account of ill-health caused by military service; and also any time not exceeding two years during which he may have been on half-pay on reduction. An officer while seconded shall continue to be eligible for selection for promotion as if he had remained on the establishment, and his service while seconded shall reckon towards such promotion.

RANK.

The Director-General of the Army Medical Service shall hold the substantive rank of Surgeon-General and shall rank in relation to combatant officers as a Lieutenant-General if recommended by the Army Council. All other Surgeon-Generals shall rank as Major-Generals in relation to combatant officers.

RETIREMENT.

An officer of the Army Medical Service will be permitted to retire in cases in which such retirement may be deemed expedient by the Secretary of State.

Scale of Retired Pay.

	Yearly.
	£
Director-General after 3 years' service in the appointment (with 30 years' service)	1125

Major, or Captain, or Surgeon-Captain of Household Cavalry—	
After 5 years' service in the rank of captain	1000
,, 3 ,, ,, major	1800
,, 6 ,, ,, ,, ...	2500
Surgeon-Lieutenant Colonel or Surgeon-Major of the Household Troops—	
After 15 years' service...	1800
,, 18 ,, ...	2500

Except in the case of a Colonel promoted after the 9th January, 1907, or a Lieutenant-Colonel, anl officer of our Army Medical Service, who, on voluntary retirement, has served for less than three years in the rank from which he retires, shall be entitled only to the gratuity or retired pay assigned to the next lower rank.

Retirement on Account of Age or Limitation of Period of Service.

The Director-General of the Army Medical Service shall retire on completion of the term of his appointment, and the retirement of other officers of the Army Medical Service except Quartermasters) shall be compulsory at the following ages: Surgeon-General, 60; Colonel, 57; and other officers, 55. A Major shall retire on completion of 25 years' service; or, if he fails to qualify for promotion, on completion of 20 years' service. A Lieutenant placed on the special list shall be retired if he fails to qualify at the next succeeding examination. A Captain placed on the special list shall, if he fails to qualify at the next succeeding examination, be retired at once on any gratuity for which he may be eligible, and if not so eligible shall be retired as soon as he completes five years' service in the rank of Captain. It shall be competent to the Secretary of State to place a medical officer on the retired list after 30 years' service.

Retirement on Account of Medical Unfitness.

An officer of the Army Medical Service or a medical officer of the Royal Malta Artillery placed on the half-pay list on account of medical unfitness shall, if not previously retired, be retired from the Army at the expiration of five years from the date on which he was placed on the half-pay list, or, if reported by the regulated medical authority to be permanently unfit for duty, on the officer's application, at such earlier date as may be decided by the Army Council.

An officer, whether on full pay or half pay, who, to the satisfaction of the regulated medical authority has been pronounced insane, shall be retired from the Army with the retired pay to which he would be entitled if reported by the regulated medical authority to be permanently unfit for duty. If his disability was not caused by military service and he is not entitled to permanent retired pay by length of service he shall receive temporary retired pay equivalent to the half pay and temporary retired pay, if any, which he would have received if his disability had been other than insanity.

Rates for Officers not qualified for Retired Pay on Voluntary Retirement.

If the unfitness was caused by military service retired pay equal to the half pay of his rank. If not so caused, provided the officer has at least 12 years' service, retired pay equal to the half pay of his rank for such period only, not exceeding five years from the date of the officer's retirement from the Army, after five years on half pay under Article 306, as the Secretary of State shall determine according to the merits of the case.

KING'S HONORARY PHYSICIANS AND HONORARY SURGEONS.

Six of the most meritorious officers of the Army Medical Service on the active list shall be named Honorary Physicians and six Honorary Surgeons. On appointment as Honorary Physician or Honorary Surgeon an officer under the rank of Colonel in the Army Medical Service may be promoted to the brevet rank of Colonel. A Lieutenant-Colonel appointed Honorary Physician or Honorary Surgeon shall receive pay at the rate laid down for a Colonel of the Royal Army Medical Corps when qualified for promotion to that rank. An officer shall relinquish the appointment of Honorary Physician or Honorary Surgeon on retirement.

MEDICAL OFFICERS OF THE REGIMENTS OF HOUSEHOLD TROOPS.

Household Cavalry.

Commissions as surgeon-lieutenants in our Household Cavalry shall be given, on the nomination of the titular colonels of the regiments, to persons approved by our Army Council.

PROMOTION.

Household Cavalry.

A Surgeon-Lieutenant shall be eligible for promotion to the rank of Surgeon-Captain on completing three and a half years' service, and a Surgeon-Major for promotion to the rank of Surgeon-Lieutenant-Colonel on completing 20 years' service. Promotion from Surgeon-Captain to Surgeon-Major shall be by seniority on the medical establishment of the brigade, but only on a vacancy occurring for such promotion.

A Surgeon-Lieutenant, Surgeon-Captain, or Surgeon-Major of our Household Cavalry may be promoted for distinguished service in the field under the conditions laid down in Article 327.

PAY.

	Daily. £ s. d.
Surgeon-Lieutenant-Colonel	1 10 0
Surgeon-Major	1 3 6
After three years' service as such	1 6 0
Surgeon-Captain...	0 15 6
After seven years' service	0 17 0
After ten years' service	1 1 0
Surgeon-Lieutenant	0 14 0

PROMOTION.

A medical officer of our Household Troops shall be eligible for extra pay under the provisions of Articles 367 and 368.

GENERAL REGULATIONS.

In all matters not provided for by Articles 382 to 387 and 555 to 562 the medical officers of our Household Troops shall be governed by the general regulations for regimental officers of our army.

EXCHANGES AND TRANSFERS.

An officer of the Royal Army Medical Corps shall be permitted to exchange with another officer of such corps, or with a medical officer of the Household Troops, under such conditions and regulations as may from time to time be made.

A medical officer of the Household Troops may be permitted to exchange with an officer of the Royal Army Medical Corps, provided that an officer exchanging into the Royal Army Medical Corps has fulfilled any conditions as to service abroad required of officers of such corps.

Exchanges between officers of the Royal Army Medical Corps under the rank of Major and medical officers of the Indian Army, and transfers of such officers from either of the above services to the other, shall only be permitted subject to the approval of the Secretary of State for India in Council and on the following conditions: (1) That the officers have less than seven years' service; (2) that the senior officer exchanging takes the place of the junior on the list and shall not be promoted until the officer next above him has been so promoted; (3) that the junior officer exchanging is placed for seniority next below all medical officers whose commissions have the same date as his own; and (4) that the officer transferred is placed for seniority below all medical officers holding the same rank at the time of his transfer and shall not be promoted until the officer next above him has been promoted.

An officer of the Royal Army Medical Corps who has exchanged or been transferred from the Indian Army shall reckon, subject to the conditions of Article 364, his previous service with the said forces towards promotion, increase of pay, gratuity, and pension.

LEAVE OF ABSENCE.

Full pay during ordinary leave of absence for the period admissible in the case of a staff officer may be granted to a medical officer provided that no additional expense is incurred thereby.

When the periods of leave referred to in Article 457 have been exhausted or exceeded in consequence of sickness no further pay during ordinary leave shall remain due.

SICK LEAVE.

An officer of the Army Medical Service may be allowed full pay during sick leave of absence on the same conditions as those laid down for regimental officers.

A regimental officer may draw full pay for the undermentioned periods during sick leave granted on the recommendation of the regulated medical authority, provided there is reasonable probability that he will ultimately be fit to return to duty:—

1. In ordinary cases for a period not exceeding 12 months.
2. In very special cases, such as loss of health due to tropical service or to active operations, the period may be extended, but it shall not exceed 18 months in all. (Article 298)

When a medical officer is sick at his station, whether in hospital, quarters, or lodgings, his absence from duty on account of sickness, if not exceeding 30 days in duration, and if duly certified by a medical officer, shall not be included in the period of absence on leave to which the issue of pay is limited by Article 457, provided the general officer commanding at the station considers that the circumstances of the case warrant such a concession. Any excess of such leave of absence on account of sickness at an officer's station beyond the period of 30 days shall come under the provisions of Article 458.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

Institution.	Title of Scholarship, &c.	Annual or Total Value.	How long Tenable.	How Obtainable.	Conditions attached to Tenure.
WESTMINSTER HOSPITAL —*continued.*	Chadwick Prize.	£21 in books or instruments.	— —	Competitive Examination among Medical Students in MEDICINE and SURGERY, including PATHOLOGY and APPLIED ANATOMY and PHYSIOLOGY.	
	Frederick Bird Medal and Prize.	£14 in medal and books or instruments.	— —	Competitive Examination in MIDWIFERY and DISEASES OF WOMEN, MEDICINE, and PATHOLOGY among Students who have completed their Fourth Winter Session at the Westminster Hospital School of Medicine.	
	Alfred Hughes Memorial Prize.	About £5 in books or instruments.	— —	Awarded annually to the candidate who during the second year in ANATOMY exhibits the highest proficiency at the class examinations in that subject held during the Winter Session.	
	Carter Gold Medal and Prize for Botany.	Gold Medal and books of the joint value of £15.	— —	Open to Students who have not exceeded three academical years from the beginning of their attendance.	
	Jelf Medal.	....	— —	Awarded annually to the Student of the third year most distinguished in examinations.	
	Second Year Scholarship.	£20.	1 year.	Subjects of Examination—ELEMENTARY ANATOMY, ELEMENTARY PHYSIOLOGY and HISTOLOGY, and ORGANIC CHEMISTRY.	
	Third Year Scholarship.	£20.	1 year.	This Scholarship is open to all Students at the end of their Third Winter and Summer Sessions. Subjects — ANATOMY, PHYSIOLOGY, and PHARMACOLOGY and MATERIA MEDICA.	
	Daniell Scholarship.	£20.	2 years.	Awarded every year to the Student who shall have executed the best researches in CHEMISTRY.	
	Babbeth Scholarship.	£20.	— —	Given annually in memory of Samuel Babbeth M.B. Lond., who sacrificed his life in an attempt to save a child who was dying from diphtheria. It is awarded to the Student who in his first year shall acquit himself best in the Class Examinations in the Preliminary Scientific Course.	
LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN	Entrance Scholarship.	£30.	— —	Competitive Examination in ENGLISH, LATIN ARITHMETIC, EUCLID, and ALGEBRA.	
	St. Dunstan's Medical Exhibition.	£60.	3 years, extendible to 5 years.	Ditto.	Candidates must be (1) not more than 20 years of age on June 1st preceding the examination; (2) resident in the Metropolitan Police District area; (3) Matriculated Students of the University of London; (4) in the opinion of the Governors in need of such an exhibition for the prosecution of their medical studies.
	Bostock Scholarship.	£60.	2 or 4 years.	Given on the result of an examination held by the University of London in June to a Student who has passed the Preliminary Scientific Examination or Intermediate Science Examination of the University of London held in the previous July or the July following the Examination.	Candidates are expected to read for the M.B. degree of the University of London. Next award June, 1911.
	Mabel Webb Research Scholarship.	£30.	1 year, renewable.	For Research Work in PHYSIOLOGY, CHEMISTRY, or PATHOLOGY.	Next award October, 1908.
	Fanny Butler Scholarship.	£14 10s.	4 years.	Application to Secretary by Sept. 1st.	Candidates must be willing to work in connexion with the Church of England Zenana Missionary Society. Next award September, 1909.
	John Byron Bursary.	£20.	2 to 4 years.	Application to Secretary by March 31st.	Offered to students already in the school requiring assistance for the prosecution of their medical studies. Next award May, 1909.

as Major-General or Lieutenant-General as may be decided in each case by the Secretary of State for India in Council.

REGULATIONS FOR THE EXAMINATION OF CANDIDATES FOR ADMISSION TO THE INDIAN MEDICAL SERVICE.

Candidates must be natural born subjects of His Majesty, of European or East Indian descent, between 21 and 28 years of age at the date of the examination, of sound bodily health, and in the opinion of the Secretary of State for India in Council in all respects suitable to hold commissions in the Indian Medical Service. They may be married or unmarried. They must possess a diploma or diplomas entitling them under the Medical Acts to practise both medicine and surgery in Great Britain and Ireland. Examinations for admission to the service usually take place twice in the year—in January and July.

They must subscribe and send in to the Military Secretary, India Office, Westminster, *so as to reach that address by the date fixed in the advertisement of the examination*, a declaration according to the annexed form.

Declaration and Schedule of Qualifications to be Filled up by Candidates.

1. Name in full... ... ...
2. Address. (*Any alteration to be notified to the Military Secretary, India Office, London, S.W.*)... ... .
3. Date of birth. (*This must be supported by a certificate or statutory declaration. See Paragraph 4 of the Regulations*) ... ...
4. Profession or occupation of father, and whether, at the time of candidate's birth, his father was a British subject of European or East Indian descent... ... ...
5. Statement as to whether the candidate is married or single ... .
6. Colleges and Medical Schools at which the candidate has received his medical education ... ...
7. Medical School in which the candidate completed his course as a medical student, and name of the Dean or other responsible authority ... ...
8. Degrees of B.A. or M.A.; details as to any prizes, university honours, &c. ... ...
9. Registrable qualification ... ...
10. Date of examination at which the candidate proposes to present himself ... ...
11. Date of any previous occasions on which the candidate may have presented himself for examination for admission to the Indian Medical Service, or other examination for the Public Services... ... ...
12. Particulars of any commission or appointment held in the Public Services... ... ...

I, , a candidate for [illegible]ce, do hereby attest [illegible] omp [illegible] my r [illegible]eed on duty immediately on being gazetted.

I declare that I labour under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer.

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief.

I inclose, in accordance with Paragraph 4 of the Regulations, (*a*) proof of age; (*b*) two certificates of character; (*c*) certificate of having attended a course of ophthalmic instruction; (*d*) evidence of a registrable qualification; (*e*) *in case of natives of India or others educated in that country only*, a certificate from the Director-General, Indian Medical Service.

Signature ....

Date .... , 19 .

This declaration must be ac[illegible] following documents:—*a. Proof of age* either by [illegible] or, where such certificate is unattainable, by the can[illegible] statutory declaration, form of which can be obtained at the India Office, supported, if required by the Secretary of State, by such evidence as he may consider satisfactory. A certificate of baptism which does not afford proof of age will be useless. *b.* A recommendation and certificate of moral character from two responsible persons—not a member of his own family—to the effect that he is of regular and steady habits and likely in every respect to prove creditable to the service if admitted. *c.* A certificate of having attended a course of instruction for not less than three months at an ophthalmic hospital or the ophthalmic department of a general hospital, which course shall include instruction in the errors of refraction. *d.* Some evidence of having obtained a registrable qualification. *e.* In the case of natives of India or others educated in that country the candidate will be required to produce a certificate signed by the Director-General, Indian Medical Service, that he is a suitable person to hold a commission in the Indian Medical Service.

The Secretary of State for India reserves the right of deciding whether the candidate may be allowed to compete for a commission in His Majesty's Indian Medical Service.

The physical fitness of each candidate will be determined by a Board of Medical Officers who are required to certify that his vision is sufficiently good to enable him to pass the tests laid down by the regulations. Every candidate must also be free from all other organic disease and from constitutional weakness or other disability likely to unfit him for military service in India. The standard of eyesight is the same as for the Royal Army Medical Corps and the physical examination is in all respects the same (see under Royal Army Medical Corps). Candidates who pass the physical examination will be required to pay a fee of £1 before being permitted to compete. No candidate will be permitted to compete more than three times.

On proving possession of the foregoing qualifications the candidate will be examined by the Examining Board in the following subjects and the highest number of marks attainable will be distributed as follows:—

	Marks.
1. Medicine, including therapeutics...	1200
2. Surgery, including diseases of the eye	1200
3. Applied anatomy and physiology...	600
4. Pathology and bacteriology	900
5. Midwifery and diseases of women and children	600
6. Materia medica, pharmacology, and toxicology	600

N.B.—The examination in medicine and surgery will be in part practical and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside No syllabus is issued in the subjects of pharmacology and toxicology, but the examination will be conducted so as to test the general knowledge of the candidate. No candidate shall be considered eligible who shall not have obtained at least *one third* of the marks obtainable in each of the above subjects and *one half* of the aggregate marks for all the subjects.

For the clinical examinations each candidate should provide himself with notebook, pencil, stethoscope, and ophthalmoscope. In drawing up reports on cases the following points should be observed, viz.: (*a*) A brief history of the case as given by patient, including such points in the family or personal history as have a distinct bearing on patient's case. (*b*) A detailed account of the subjective symptoms and physical signs elicited by the candidate's personal examination of the patient, noting the absence of any which might be expected to be present in a similar case (*c*) Where there is any reasonable doubt in the mind of the candidate as to the exact diagnosis he is to give the alternatives, with his reasons for making the selection. (*d*) A commentary upon the case as a whole, pointing out the symptoms which may be considered typical and those which appear to be unusual or only accidental complications. (*e*) Suggestions as to treatment, both immediate and possibly necessary at a later date. (*f*) A forecast of the progress and probable termination of the case.

After passing this examination the successful candidates will be granted about a month's leave and will then be required to attend two successive courses of two months each at Aldershot and at the Royal Army Medical College, Millbank.

The course at Aldershot will include instruction in (1) internal economy, (2) Indian military law, (3) hospital administration, (4) stretcher and ambulance drill, (5) equitation, and (6) map reading.

The course at the Royal Army Medical College will be in (1) hygiene, (2) military and tropical medicine,[3] (3) military surgery, and (4) pathology of diseases and injuries incidental to military and tropical service.

From the day on which the result of the examination is announced lieutenants on probation will receive an allowance of 14*s.* per diem, with quarters (where quarters are not provided, with the usual allowances of a subaltern in lieu thereof), to cover all costs of maintenance, and he will be required to provide himself with uniform (viz., the regulation undress uniform and mess dress of a Lieutenant of the Indian Medical Service, as described in Indian Army Regulations, Vol. VII., with Sam Browne belt, but without the sword).

A lieutenant-on-probation who is granted sick leave before the completion of his course of instruction and final admission to the service will receive furlough pay at the rate of 10*s.* 6*d.* a day for the period of his sick leave.

Candidates will be required to conform to such rules of discipline as may from time to time be laid down.

At the conclusion of the course candidates will be required to pass an examination on the subjects taught during the course of instruction.

Officers appointed to the Indian Medical Service will be placed on one list, their position on it being determined by the combined results of the preliminary and final examinations. They will be liable for military employment in any part of India, but in view to future transfers to civil employment, they will stand posted to one of the following civil areas:—(1) Madras and Burma; (2) Bombay with Aden; (3) Upper Provinces—i.e., United Provinces, Punjab, and Central Provinces; and (4) Lower Provinces—i.e., Bengal, and Eastern Bengal and Assam. The allocation of officers to these areas of employment will be determined upon a consideration of all the circumstances, including, as far as possible, the candidate's own wishes. Officers transferred to civil employment, though ordinarily employed within the area to which they may have been assigned, will remain liable to employment elsewhere according to the exigencies of the service.

---

[3] In our opinion as long as the lieutenants-on-probation of the Indian Medical Service receive their instruction at the College, the post of Professor of Medicine in the College should be held by a distinguished officer of the Indian Medical Service and not as at present by an officer of the Royal Army Medical Corps who has had no training as a teacher and does not possess any special knowledge of tropical diseases. The lectures on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad, the management of lunatics under the conditions of military service, &c. The lieutenants-on-probation of both services will attend the New Millbank Hospital where they will be taught practically the details of the management of patients in a military hospital, and the registration of their diseases, the duties of invaliding, the modes of filling up the regulation statistical returns, and other service documents. No provision for instruction in lunacy has as yet been made in London. While in London the lieutenants-on-probation for both services now reside at the St. Ermin's Hotel, Westminster. The candidate's commission as lieutenant will bear the date on which the result of the examination is announced, but his rank will not be gazetted until he has passed the final examination.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
UNIVERSITY OF DURHAM *(College of Medicine)—continued.*	Tulloch Scholarship.	Interest on £400.	— —	Examination in ANATOMY, PHYSIOLOGY, and CHEMISTRY.	No Student is eligible who commenced his medical curriculum more than two academical years before the date of examination.
	Charlton Memorial Scholarship.	Interest on £700.	— —	Examination in Medicine.	Open to full Students of the College entered for the class on the Principles and Practice of Medicine.
	Gibb Scholarship.	Interest on £500.	— —	Awarded annually as a Scholarship in PATHOLOGY to full Student who passes the best examination in that subject.	No Student eligible after completion of his curriculum.
	Luke Armstrong Memorial Scholarship.	Interest on £680	— —	Original Essay on some subject in COMPARATIVE PATHOLOGY. (If no Essay of sufficient merit be presented the Scholarship may be awarded to the Candidate who, in passing the first part of the Examination for the B.Hy. Degree, obtains the highest number of marks in COMPARATIVE PATHOLOGY during the year.)	Open to all Graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University, and whose age does not exceed 30 years.
	Stephen Scott Scholarship.	Interest on £1000.	— —	Original Essay on any Surgical subject.	Any Graduate in Medicine or Surgery of the University or any Student of the College of Medicine. Student's age must not exceed 30 years.
	Heath Scholarship	Interest on £4000.	— —	For 1908 – Original Essay on INJURIES AND DISEASES OF THE ARTERIES, VEINS, AND CAPILLARIES, AND THEIR TREATMENT.	All Graduates in Medicine or Surgery of the University are eligible.

	Cartwright.*	£35.	3 years.	Ditto.	

* Open to men candidates only.

by him, or that he is the son or *grandson of a person born in His Majesty's* Dominions, the certificate will be refused and the candidate will be unable to obtain admission to the competitive examination for the Indian Medical Service.

A course of instruction in *sanitary methods, rules,* and regulations as carried out in Indian cantonments was instituted last winter for young officers of the Indian Medical Service and the Royal Army Medical Corps on first arrival *in the country.* The nature of the diseases to be combated, the social and religious customs and prejudices of the various races, and the limited resources of money and material make large modifications from European methods necessary. Lieutenants of both services are now posted on arrival either to Rawal Pindi, Poona, Lucknow, or Bangalore for *one month for this course,* which is carried out under the supervision of the senior medical officer and sanitary officer. The instructors are medical officers nominated by the principal medical officer, India, and demonstrations on various subjects have been given by other officers, *staff, engineer,* and medical. The course consists of demonstrations and inspections in all parts of the lines of British and Indian troops, bazaars, Government dairies, bakeries, slaughter-houses, trade premises of dairymen, bakers, butchers, and aerated water manufacturers *and hobies' houses, market* and water-supplies, methods of washing clothes, surface drainage, removal and disposal of sewage and refuse, antimalarial measures, disinfection, cantonment hospitals, control of venereal diseases, plague prevention, methods of hospital administration, &c. The *officers under instruction thus have an opportunity* of learning something of native customs and are encouraged to learn the vernacular, so as to be less dependent upon their subordinates when first put in responsible positions.

A Lieutenant may be promoted to the rank of Captain on *completing three years' full-pay service from the date of first* commission, but after completing 18 months' service and before promotion to the rank of Captain he will be required to pass an examination in military law and military medical organisation, the result of which may affect his promotion. *With reference to the extract from the Gazette of India,* Medical Department, No. 1047, dated Oct. 24th, 1903, paragraph 4, it is notified that the Government of India has decided that the scope of the examination which lieutenants of the Indian Medical Service will be required to pass *after completion of 18 months' service* will be as follows: Subject (*h*) Text-books, the relevant portions of the Army Regulations of India, vols. ii. and vi., and the Field Service Departmental Code (Medical). Subhead (*a*) (2): *The* duties of the subordinate *personnel* of native military hospitals *and the preparation of returns* and requisitions connected therewith. Subhead (3): The duties of executive medical officers of the Indian Medical Service. Subject (*d*), subhead (2): Indian military law and Indian articles of war as laid down for officers of the Supply and *Transport Corps* in G.O.C.C. 897 of 1902. One paper will be set in each of subheads (2) and (3) of subject (*h*). The time allowed for each paper will be three hours. The examinations will take place at district headquarters twice annually, on March 1st and *Oct. 1st, simultaneously with those* for other officers, commencing on Oct. 1st, 1904. The standard required will be for a pass 5 in (*h*) and 5 in law: for special certificate 8 in (*h*) and 8 in law. An officer may present himself for examination in the above subjects *either separately or conjointly.* The above rules apply only to officers appointed to the Indian Medical Service on or after Jan. 31st, 1900. The names of candidates for examination will be submitted by general officers commanding *districts to the Director of Military* Education in India so as to reach that officer by Sept. 1st and Feb. 1st annually. Captains are promoted to the rank of Major after 12 years' full-pay service, but this promotion is accelerated by six months in the case of officers who *fulfil* certain specified conditions. A Major is promoted to Lieutenant-Colonel on completion of of eight years' full-pay service in the rank of Major. All promotions to higher grades are given by selection for ability and merit. In case of distinguished service in the field a medical *officer may* receive substantive or brevet rank. The *ages* for compulsory retirement are the same as those for the Royal Army Medical Corps. Officers of the Indian Medical Service below the rank of *Colonel may* be granted: 1. Privilege leave *under such* regulations as may from *time to time* be in force. 2. Leave out of India for no longer period than one year, capable of extension to two years' absence from duty, on the *following pay for officers* in military employment (*officers in* civil *employment* are entitled to higher rates):—*After* arrival in India, on first *appointment, £250 a year;* after the commencement of the *tenth year's service for pension,* £300 a year; after the commencement of the fifteenth *year's service for pension,* £450 a year; after the commencement of the twentieth year's service for pension, £600 a year; and *after the* commencement of the twenty-fifth year's service for pension, £700 a year. 3. Leave in India, but for the period of one year only, on full military pay and half the staff salary of appointment. No extension of leave involving absence from duty for more *than two years,* whether taken in or out of India, can be granted except on specially urgent grounds and without pay. An officer unable on account of the state of his health to return to duty within the maximum period of two years' absence, unless he is specially granted an extension of leave *without pay, is placed on temporary* half-pay or the retired list, as the *circumstances of the case may require.* An officer is also liable to be placed on half-pay or the retired list should his health require an undue amount of leave, whether in or out of India. Leave may be granted at any *time, but solely at the discretion of the civil or military* authorities in India under *whom an officer may be serving. Officers of the Administrative grades may be granted one* period of leave not exceeding eight months during their tenure of appointment. Extra furlough may be granted to *officers desirous of pursuing special courses of study* at the rate of one month's furlough for each year's service up to 12 months in all. During such leave the ordinary furlough pay will be given with lodging allowances of 4*s*., 6*s*., and 8*s*. a day for Lieutenants, Captains, and field officers respectively. *An officer on leave is required to join at once* on being recalled to duty unless certified by a medical board as unfit to do so.

PAY AND ALLOWANCES.

The rate of pay drawn by Lieutenants of the Indian Medical Service *previous to arrival in India is 14s. a day, but a Lieutenant* (1) who has been permitted by the Secretary of State to hold a hospital appointment will receive no pay while holding it; (2) who is detained by *illness* in this country will be paid at the rate of £250 *a year from the date on* which he would otherwise have embarked until the date of embarkation, *and at the rate of 14s. a day during the voyage to India.*

Pay at the above rate is issued in this country up to the date of embarkation, and an advance of two months' pay at the *same rate is* also made prior to embarkation, which is adjusted in India.

The following are the monthly *rates of Indian pay* drawn by officers *of the Indian Medical Service from the date of their arrival in* India:—

Rank.	Unemployed pay.	Grade pay.	Staff pay.	In officiating medical charge of a regiment.	In permanent medical charge of a regiment.
	Rs.	Rs.	Rs.	Rs.	Rs.
Lieutenant	420	350	150	425	500
Captain	475	400	150	475	550
" after 5 years' service ...	475	450	150	525	600
" after 7 years' service ...	—	500	150	575	650
" after 10 years' service ..	—	550	150	625	700
Major	—	650	150	725	800
" after 15 years' service ...	—	750	150	825	900
Lieutenant-Colonel	—	900	350	1075	1250
" " after 25 years' service	—	900	400	1100	1300
" " specially selected for increased pay	—	1000	400	1200	1400

NOTES.—(*a*) Unemployed pay is drawn by officers of less than seven years' service who are not holding officiating or substantive charge of native regiments. *Officers of more than seven years' service* draw grade pay alone when unemployed. *Staff* pay is the pay of a command and is drawn in addition to grade pay.

(*b*) Horse allowance is granted to officers in charge of cavalry regiments at the rate of Rs. 90 a month to *Lieutenant-Colonels* and Majors, and Rs. 60 a month *Captains* and *Lieutenants.*

Note to paras 16 to 20.—Under present arrangements, officers of the Indian Medical Service who are not *statutory* natives of India receive exchange compensation allowance to compensate them for the fall of the value of the rupee. The allowance consists *of an addition* to their salaries (*subject to certain limitations*) equal to half the difference between their salaries converted at (1) 1*s*. 6*d*. the rupee, and (2) the standard Government rate, which *has been* fixed at 1*s*. 4*d*. the rupee until further notice.

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries:—

Rs. per mensem.
Colonel, 16 (some in civil employ) from ... ... 1800 to 2500
Surgeon-General, 1 @ ... ...
" 2 @ ... ...
" (the Director-General I.M.S.) 1

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued.*

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
UNIVERSITY OF MANCHESTER—*continued.*	Professor Tom Jones Memorial Surgical Scholarship.	£100.	1 year.	The scholar will be elected on the result of evidence submitted by him.	Candidates must have either graduated in the University or have obtained the Diploma of the Conjoint Colleges.
	Dumville Surgical Prize.	£15.	— —	Subjects: SYSTEMATIC, PRACTICAL, and OPERATIVE SURGERY, SURGICAL ANATOMY, and SURGICAL PATHOLOGY.	
	Honorary Research Fellowships.	— —	2 years.	Conferring the right of free use of the Laboratories. Awarded generally in October on application, with evidence of capacity for independent investigation.	
	Leech Fellowship.	£100.	......	Awarded annually for excellence and promise in one or more of the subjects of the Second or Final M.B. Examination.	
	Graduate Scholarship in Medicine.	£25 to £50.	1 year.	Awarded on results of Second Examination for M.B., Ch.B.	
UNIVERSITY COLLEGE, BRISTOL, BRISTOL ROYAL INFIRMARY, AND BRISTOL GENERAL HOSPITAL	Medical Entrance Scholarship.	£75.	— —	Competitive Examination in Subjects of GENERAL EDUCATION.	
	Tibbits Surgical Prize.	£9 9s.	— —	Proficiency in PRACTICAL SURGERY.	Open to Perpetual Students of Faculty of Medicine, *University College*, Bristol.
	Martyn Memorial Pathological Prizes.	Two annually, of £10 each.	— —	Competitive Examination in PATHOLOGY and MORBID ANATOMY.	
	A Gold and a Silver Medal.	— —	— —	Given by the Committees *of the two* Institutions to most distinguished Students of Fifth Year.	
Bristol Royal Infirmary ...	Suple Medical Prize.	Gold Medal value £5 5s. and £7 7s. in money.	— —	Competitive Examination in MEDICINE to Students of Fourth and Fifth Years.	Restricted to Perpetual Students who have done the necessary qualifying work at the Bristol Royal Infirmary.
	Suple Surgical Prize.	Gold Medal value £5 5s. and £7 7s. in money.	— —	Competitive Examination in SURGERY of Students of Third and Fourth Years.	
	Henry Clark Prize.	£11 11s	— —	Class Work *of Third-year Students.*	
	Crosby Leonard Prize.	£7 7s.	— —	Examination in CLINICAL SURGERY.	
	Augustin Prichard Prize.	£6 6s.	— —	Examination in SURGICAL ANATOMY.	
Bristol General Hospital ...	Sanders Scholarship.	£22 10s.	— —	Competitive Examination in MEDICINE, SURGERY, and MIDWIFERY of Fourth-year Students.	Restricted to Perpetual Students who have done the necessary qualifying work at the *Bristol* General Hospital.
	Clarke Scholarship.	£15.	— —	Competitive Examination in SURGERY among Students of Fourth Year.	
	Marshall Prize.	£12.	— —	To the best Surgical Dresser of the Fourth Year.	
THE UNIVERSITY, LEEDS (SCHOOL OF MEDICINE)	Entrance Scholarship.	£73 2s. 6d.	— —	Joint Matriculation Board Examination held in July.	Complete Course of Lectures and Practical Classes at Leeds School.
	Infirmary Scholarship.	£42.	— —	On the results of the First M B. Examination of the University of Leeds.	Complete Course *of* Hospital Practice and Clinical Lectures at Leeds Infirmary.
	Hardwick Prize.	£10.	— —	Competitive Examination in CLINICAL MEDICINE among Clinical Clerk Students of *two years' standing.*	
	McGill Prize.	£10.	— —	Competitive Examination among advanced Surgical Students in CLINICAL SURGERY.	
	Thorp Prizes.	£10 and £5.	— —	Examinations in Forensic Medicine and Hygiene.	
	Thorp Prize Essay.	£15.	— —	Essay or Research on some subject connected with FORENSIC MEDICINE, TOXICOLOGY, or PUBLIC HEALTH.	*Every three years* to former students of the Leeds School.
	Scattergood Prize.	£5.	....	Examination in MIDWIFERY.	
UNIVERSITY OF LIVERPOOL	Robert Gee Entrance Scholarships (two annually).	£25 each.	2 years.	Joint Matriculation Board Examination held in July.	First M.B. Course.
	Lyon Jones Scholarship. No. 1.	£21 per annum.	2 years.	Competitive Examination among Junior Students in First M.B. *SUBJECTS.*	Perpetual Course at the University.
	" No. 2.	£21.	— —	Competitive Examination among Senior Students in ANATOMY, PHYSIOLOGY, and THERAPEUTICS.	
	Derby Exhibition.	£15.	— —	Competitive Examination among Fourth- or Fifth-year Students in CLINICAL SUBJECTS.	
	Holt Fellowships (Physiology and *Pathology*).	£100 each.	1 year.	Vote of Faculty to Student after graduation.	Teaching and Original Research.
	Gee Fellowship (Anatomy).	£100.	1 year.	Ditto.	Teaching and Research.
	Alexander Fellowship (Pathology).	£100.	1 year.	Ditto.	Research in Pathology.

Oxford: *Radcliffe Infirmary*. *Sheffield*: Royal Infirmary and Royal Hospital. Scotland.—Aberdeen: Royal Infirmary. Dundee: Royal Infirmary. Edinburgh: Royal Infirmary. Glasgow: Royal Infirmary and Western Infirmary. Ireland.—Belfast: *Royal Victoria Hospital*. Cork: North Infirmary and South Infirmary. Dublin: the Adelaide Hospital, the City of Dublin Hospital, the Jervis Street Hospital, the Mater Misericordiæ Hospital, the Meath Hospital, Mercer's Hospital, the Richmond, Whitworth, and Hardwicke Hospital, St. Vincent's Hospital, *Sir Patrick Dun's Hospital*, and Dr. Steevens's Hospital. Galway: The *County Hospital* and the Union Hospital.

The Royal *Army Medical Corps* is at the *present time*, we believe, *a contented service, though the Director-General* A.M.S. *is excluded from the* Army Council, before which he will, however, be summoned whenever *his advice* and specialist knowledge are required. The relationship of the Director-General to the War Council should be direct and personal. The limitation of the number of lieutenant-colonels has, of course, affected adversely some officers who are well worthy *of promotion to the highest ranks*, and we look to the Director-General to arrange that really *deserving* officers may not suffer through the introduction of a regulation which would rob the service of officers who have done some of the best work for the Royal Army Medical Corps.

The blots on the present regulations for the Indian Medical Service are as follows :—

1. That *no officer, however employed, can* receive any *staff allowance* unless he has passed the lower *standard* examination in Hindustani.

2. That an officer who enters the service after his 25th birthday forfeits almost to a *certainty his chance* of ever reaching a higher *pension than* £500 per annum.

3. The *order* of the *present Government* of India that an officer of the Indian Medical Service must refer the *question of the amount of his fees* when *above* a certain low limit to the civil authority. The recent orders might *necessitate the violation of professional secrecy*.

4. The neglect *of the rule that* the office of principal medical *officer to His Majesty's* forces may be held by an *officer of the* Indian Medical Service.

SPECIALIST PAY FOR OFFICERS OF THE ROYAL ARMY MEDICAL CORPS AND INDIAN MEDICAL SERVICE IN INDIA.

The Government of India has just approved of revised rules in connexion with specialist appointments in India. 55 of the appointments will be allotted to the Royal Army Medical Corps and 50 to the Indian *Medical Service* in military *employment*. The Specialist pay (Rs. 60 a month) is an allowance *to officers below* the rank of Lieutenant-Colonel for special sanitary, *surgical*, or *medical work done for* the State. The *following is a list of appointments*:—

	Rs.
(*a*) Prevention of [illegible] logy, and p[illegible]	40
(*b*) Dermatology . [illegible] and instructional measures in connexion with, venereal diseases)	10
(*c*) Advanced operative surgery	20
(*d*) Ophthalmology	10
(*e*) Electrical science (including skiagraphy)	10
(*f*) Mental science	2
(*g*) Otology, laryngology, and rhinology	3
(*h*) Midwifery and diseases of women and children ...	10

Selections *for appointments* and the *distribution* throughout the several divisions and brigades will be made under the orders of His Excellency the *Commander-in-Chief*, the guiding principle, however, being that officers will *be located* in those stations where their services are likely to be of the *greatest utility to the army*.

It does not appear probable to us that the above rules will attract *many men to the rank of the so-called specialist or* that the Government can regard with much esteem a *status for which it can frame such regulations*.

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN *STATE MEDICINE*.

THE following resolutions, designed with a view of ensuring "*the possession* of a distinctively high proficiency, *scientific* and practical, in all the branches of *study* which concern the public health," were adopted *by the General* Medical Council from 1902 to 1905. The regulations require that—"(1) A *period of* not less than twelve months shall elapse between the attainment of a registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health or *State* Medicine; (2) every candidate shall produce evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory; British or foreign, approved *of by the body* granting the diploma and in which *chemistry*, bacteriology, and the pathology of diseases of animals transmissible to man are taught; (3) every candidate shall produce evidence that, after having obtained a registrable qualification, he *has for six* months (of which at *least* three months shall be distinct and separate *from* the *period* of laboratory *instruction*) *practically* studied the duties, routine and *special*, of *Public Health* administration either under a whole-time medical officer of health or a medical officer of health who is also a *teacher in public health* in a recognised *school*, or in England and Wales under the *medical* officer of health of a county or of a *single sanitary district of 50,000*, or in one or *more* districts of 30,000 *in* Scotland or Ireland, *or under* a sanitary *staff* officer of the Royal Army Medical Corps having *charge of an army corps, district*, or *command* recognised by the General Medical Council, provided that the *six* months may be reduced to three if a candidate produces evidence *that* after obtaining a registrable qualification he has for three months attended a *course* of *recognised* instruction in sanitary law, sanitary engineering, vital statistics, and other *subjects* bearing on Public Health administration; (4) every candidate shall produce *evidence that after* having obtained a registrable qualification he *has* attended during three months the practice of a hospital for *infectious* diseases at which opportunities are *afforded for the study* of methods of administration; (5) the examination shall have been conducted by examiners *specially* qualified, *and* shall comprise laboratory work as well as *written* and oral examination; (6) the rules *as* to study *shall* not apply to medical practitioners registered, *or entitled* to be registered, on or before Jan. 1st, 1890." *It was enacted by Section 18 (2)* of the Local Government Act [England and Wales], 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in *any county*, or *in any district* or combination of *districts* with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—*is registered as* the holder of a diploma in Sanitary Science, Public Health, or State Medicine *under* Section 21 of the Medical Act, 1886, or has during any three consecutive *years* preceding 1892 *been* medical officer of a district or combination of districts with a *population of* 20,000 at least, or has for three years *previously* to August 13th, 1888, been a *medical officer* or inspector of the Local Government Board. With the sanction of the Local Government Board the *same* person may be appointed medical *officer for two or* more districts.

The regulations in question as to study may be procured at the office of the General Medical Council in London.

University of London.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, *and* that the course has included such chemical, microscopical, and *meteorological* work and exercises as more especially relate to *sanitation*. The attendance includes six months' practical *instruction in a laboratory* and six months' *instruction in public* health administration under the supervision of a medical *officer* of health, and three *months' attendance* on the practice *of a hospital* for infectious diseases.

University of Oxford.—An examination, *open to* all registered medical practitioners, conducted partly in writing, partly *vivâ voce*, and in each subject partly practical, is held in Michaelmas Term in *the following subjects*:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination *is* in two parts, which may be taken *together or separately*; but Part I. *must* be *passed* either before or at the *same examination as Part II.* The *fee for admission* to the examination is £5 for each part. The names of candidates *must* be sent to the Secretary to the Boards of *Faculties*, to whom applications for any further *information should* be made.

University of Cambridge.—Two *examinations* in so much of State Medicine as is comprised in the functions of medical officers of health will be *held during* the year 1907–8 in Cambridge. Each examination will consist of two parts. *Part I.* will begin on the first Wednesday in April and October respectively; Part II. will begin on the Monday following in *April and* October respectively; and each part will *end* on the following Thursday. Any person whose *name is on the* Medical Register is admissible as a *candidate* for this examination provided (1) a period of not less than twelve

Dublin: the Adelaide Hospital, the City of Dublin Hospital, the Jervis Street Hospital, the Mater Misericordiæ Hospital, the Meath Hospital, Mercer's Hospital, the Richmond, Whitworth, and Hardwicke Hospital, St. Vincent's Hospital, Sir Patrick Dun's Hospital, and Dr. Steeven's Hospital. Galway: The County Hospital and the Union Hospital.

The Royal Army Medical Corps is at the present time, we believe, a contented service, though the Director-General A.M.S. is excluded from the Army Council, before which he will, however, be summoned whenever his advice and specialist knowledge are required. The relationship of the Director-General to the War Council should be direct and personal. The limitation of the number of lieutenant-colonels has, of course, affected adversely some officers who are well worthy of promotion to the highest ranks, and we look to the Director-General to arrange that really deserving officers may not suffer through the introduction of a regulation which would rob the service of officers who have done some of the best work for the Royal Army Medical Corps.

The blots on the present regulations for the Indian Medical Service are as follows:—

1. That no officer, however employed, can receive any staff allowance unless he has passed the lower standard examination in Hindustani.

2. That an officer who enters the service after his 25th birthday forfeits almost to a certainty his chance of ever reaching a higher pension than £500 per annum.

3. The order of the present Government of India that an officer of the Indian Medical Service must refer the question of the amount of his fees when above a certain low limit to the civil authority. The recent orders might necessitate the violation of professional secrecy.

4. The neglect of the rule that the office of principal medical officer to His Majesty's forces may be held by an officer of the Indian Medical Service.

SPECIALIST PAY FOR OFFICERS OF THE ROYAL ARMY MEDICAL CORPS AND INDIAN MEDICAL SERVICE IN INDIA.

The Government of India has just approved of revised rules in connexion with specialist appointments in India. 55 of the appointments will be allotted to the Royal Army Medical Corps and 50 to the Indian Medical Service in military employment. The Specialist pay (Rs. 60 a month) is an allowance to officers below the rank of Lieutenant-Colonel for special sanitary, surgical, or medical work done for the State. The following is a list of appointments:—

	Rs.
(*a*) Prevention of disease (including parasitology, bacteriology, and preventive inoculation	40
(*b*) Dermatology (including the prophylaxis, treatment of, and instructional measures in connexion with, venereal diseases)	10
(*c*) Advanced operative surgery	20
(*d*) Ophthalmology	10
(*e*) Electrical science (including skiagraphy)	10
(*f*) Mental science	2
(*g*) Otology, laryngology, and rhinology	3
(*h*) Midwifery and diseases of women and children ...	10

Selections for appointments and the distribution throughout the several divisions and brigades will be made under the orders of His Excellency the Commander-in-Chief, the guiding principle, however, being that officers will be located in those stations where their services are likely to be of the greatest utility to the army.

It does not appear probable to us that the above rules will attract many men to the rank of the so-called specialist or that the Government can regard with much esteem a status for which it can frame such regulations.

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

THE following resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council from 1902 to 1905. The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health or State Medicine; (2) every candidate shall produce evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory, British or foreign, approved of by the body granting the diploma and in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught; (3) every candidate shall produce evidence that, after having obtained a registrable qualification, he has for six months (of which at least three months shall be distinct and separate from the period of laboratory instruction) practically studied the duties, routine and special, of Public Health administration either under a whole-time medical officer of health or a medical officer of health who is also a teacher in public health in a recognised school, or in England and Wales under the medical officer of health of a county or of a single sanitary district of 50,000, or in one or more districts of 30,000 in Scotland or Ireland, or under a sanitary staff officer of the Royal Army Medical Corps having charge of an army corps, district, or command recognised by the General Medical Council, provided that the six months may be reduced to three if a candidate produces evidence that after obtaining a registrable qualification he has for three months attended a course of recognised instruction in sanitary law, sanitary engineering, vital statistics, and other subjects bearing on Public Health administration; (4) every candidate shall produce evidence that after having obtained a registrable qualification he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration; (5) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (6) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act [England and Wales], 1888, that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previously to August 13th, 1888, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board the same person may be appointed medical officer for two or more districts.

The regulations in question as to study may be procured at the office of the General Medical Council in London.

University of London.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' instruction in public health administration under the supervision of a medical officer of health, and three months' attendance on the practice of a hospital for infectious diseases.

University of Oxford.—An examination, open to all registered medical practitioners, conducted partly in writing, partly *virâ voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £5 for each part. The names of candidates must be sent to the Secretary to the Boards of Faculties, to whom applications for any further information should be made.

University of Cambridge.—Two examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1907–8 in Cambridge. Each examination will consist of two parts. Part I. will begin on the first Wednesday in April and October respectively; Part II. will begin on the Monday following in April and October respectively; and each part will end on the following Thursday. Any person whose name is on the Medical Register is admissible as a candidate for this examination provided (1) a period of not less than twelve

QUEEN'S COLLEGE, GALWAY	Eight Junior Scholarships.	£25 each and half fees.	1 year.	Competitive Examination at the commencement of session.	Students of either sex must be of the standing of the year, and may be of any recognised school of medicine.
QUEEN'S COLLEGE, CORK	Eight Junior Scholarships for Matriculated Students, two for each of first four years of curriculum.	£25.	1 year.	Examination at commencement of session.	Open to matriculated students of either sex.
	Blayney Scholarship, in fifth year of curriculum.	£32.	1 year.	Ditto.	Ditto.
	Senior Exhibition, in fifth year of curriculum.	£30.	1 year.	Ditto.	Ditto.
	Three Exhibitions in Practical Medicine, Surgery, and Midwifery respectively.	£15 each.	......	Examination at end of medical session.	

Chemistry, and Physics. They have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B Hy. is 10 guineas and for the degree £6 6s. The examination is divided into two parts and candidates may present themselves for either part or both together at their option. Candidates for the degree of Doctor of Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a medical officer of health, and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5 and for the degree £6 6s. The regulation for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and Diploma in Public Health is 10 guineas.

Victoria University of Manchester.—An examination in Public Health is held twice yearly under the following regulations: The examination is in two parts and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health in the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University, the courses including Chemistry as applied to Public Health, Bacteriology, and the Pathology of those diseases of animals which are communicable from animals to man; of having, after obtaining a registrable qualification, attended for three months the clinical practice of a hospital for infectious diseases; of having, after obtaining a registrable qualification, practically studied the duties of outdoor sanitary work for not less than six months under the medical officer of health of a county or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5s. and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3s. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the middle of January and the middle of July in each year.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health, by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University and they must, in addition, have attended a three months' course of Geology in the University. The following are the regulations for Diploma in Public Health (general conditions):—1. All candidates must be registered under the Medical Act. 2. The examinations will be held in the months of January and June and will consist of two parts. No candidate will be allowed to pass Part II. until he has passed Part I. 3. Candidates may enter for Parts I. and II. separately or at the same time. 4. The examination in each part will be written, oral, and practical. 5. Candidates intending to present themselves for either part of the examination, must give notice in writing to the registrar of the University on the date prescribed in the calendar. 6. The fee for each part of the examination is £2. Admission fee to degree or diploma, £6. The conditions of admission to the examinations are identical with those recently approved by the General Medical Council.

Officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the staff College and pursued the further course of study approved by the General Medical Council in December, 1902, will be admitted to the Examination for the Diploma in Public Health, whether they have previously been students of the Birmingham School or not.

University of Liverpool.—The University grants a Diploma in Public Health and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the various D.P.H. Examinations demands (1) a six months' course of practical instruction in Sanitary Science; (2) a six months' course of laboratory instruction in Chemistry and Bacteriology; and (3) practical instruction in Infectious Diseases. Fees.—Chemistry, £5 5s.; Bacteriology, £5 5s.; Practical Sanitation, £25; Tutorial Classes, £7 7s.; Infectious Diseases, £3 3s. The courses may be taken out at any time and students are allowed to work daily in the laboratories.

University of Leeds.—The University grants a Diploma in Public Health and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in July and December—is in two parts, and is written, oral, and practical. Candidates, before entering for the first part of the examination, must have held for not less than 12 month a registrable qualification in Medicine, Surgery, and Midwifery and must present satisfactory certificates (1) o having attended an approved course of instruction in Publi Health in the University, or in a college or medical schoo recognised for this purpose by the University; (2) of havin attended, after obtaining a registrable qualification, durin at least six months practical instruction in laboratorie approved by the University, the courses including Chemistr as applied to Public Health, Bacteriology, and the Patholog of those diseases of animals which are communicable fron animals to man. Candidates before entering the second par of the examination must present certficates (3) of having after obtaining a registrable qualification, attended durin not less than three months the clinical and administrativ practice of a hospital for infectious diseases approved b the University; (4) of having, after obtaining a registrabl qualification, during six months (of which at least thre months shall be distinct and separate from the period o laboratory instruction required under 2), been diligentl engaged in acquiring a knowledge of the duties, routine an special, of Public Health administration under the supervision of (*a*) the medical officer of health of a county or o a single sanitary district having a population of not les than 50,000, or (*b*) a medical officer of health devotin his whole time to Public Health work, or (*c*) a medica officer of health who is also a teacher in the Departmen of Public Health of a recognised medical school, o (*d*) a sanitary staff officer of the Royal Army Medical Corp having charge of an Army Corps, district, or comman recognised for the purpose by the General Medical Counci or of having attended during three months as require above, and during three months after obtaining a registrabl qualification, having attended a course or courses of instruction, approved by the University, in subjects bearing o Public Health Administration. Candidates may presen themselves for Parts I. and II. separately or at the sam time, provided that no candidate be allowed to pass in Part II unless he has already passed in Part I. No candidate's nam will be published until he has satisfied the examiners in bot parts of the examination. Fees—The fee for each part i £5 5s., and must be paid at least 14 days before the commencement of the examination. For any subsequent examination in the same part the fee will be £3 3s. Ever candidate who has passed both parts of the examinatio and who is legally registered will receive a Diploma in Publi Health. Medical practitioners registered or entitled to b registered on or before Jan. 1st, 1890, may be exempted fron producing the above required certificates of study.

University of Sheffield.—At this University courses o instruction have been arranged for the Diploma in Publi Health which qualify for the Cambridge University Diploma for that given by the Conjoint Board of England, and for th degree of M.D. in State Medicine of the University o London.

University of Edinburgh.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh, viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. Candidates for the degree of B.Sc. in Public Health must be graduates in of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German. The examination in chemistry will include the general principles of inorganic and organic chemistry; the preparation and properties of the chief non-metallic and metallic elements and their compounds; the preparation, properties and classification of the more important compounds, such as marsh gas, ethylene, acetylene, methyl and ethyl alcohols, glycerin, ether, formic, acetic, lactic and oxalic acids; cyanogen and cyanides; carbohydrates; fats; proteids. The examination in physiology will comprise the minute structure and functions of the various tissues and organs of the body; the physiology of the blood; the nature of food and the processes of its digestion; the mechanics of the circulation and of respiration; the physiology of nutrition, secretion, and excretion; animal heat, the nature of sensation, volition, reflex action, inhibition and influence of the nervous system on other organs and their functions. The examination in zoology will include—the general principles of biology, and a comparison of animals with plants; the distinctive characters of the larger groups of animals—the protozoa, cœlenterata, vermes, arthropoda, mollusca, echinodermata, and vertebrata—as illustrated by common types; the elements of embryology; animal parasites. The examination in botany will comprise the general principles of the morphology and physiology of low forms of life—e.g., torula, bacteria, spirogyra, moss fern; the general morphology of flowering plants; diagnosis of the important British natural orders; medicinal plants. The examination in geology and physical geography will be limited to general principles, such as: the relations of the earth to the rest of the solar system; nature of the earth's crust and the chief kinds of rocks; general configuration of land and water, mountains, plains, islands, rivers, lakes, glaciers and icebergs, ocean currents, tides, winds, storms, dew, rain, climate, vulcanoes, earthquakes, distribution of animal and vegetable life.

The appointments announced for competition will be filled from the list of qualified candidates, arranged in order of merit; but should it at any time be considered expedient to grant Commissions beyond those periodically competed for, the Admiralty have power to admit annually (a) two candidates—proposed by the governing bodies of schools of medicine in the United Kingdom—who have satisfactorily filled the office of house surgeon in a large civil hospital for at least six months; and (b) not more than six candidates, according to requirements, specially recommended by the governing bodies of such colonial universities as may be selected and whose qualifications are recognised by the General Medical Council. Candidates so proposed are to be approved by the Director-General of the Medical Department of the Navy and are to be certified by the governing body proposing them as duly qualified according to the regulations in force for the entry of candidates. In cases of colonial nominations, registration of professional qualifications may be deferred until after the arrival in England of a candidate who has been passed on the station, but a Commission as Surgeon will not be granted until the certificate of the Registrar of the Medical Council has been produced at the Medical Department of the Navy. Candidates from schools at home will be required to pass a physical examination in London which will be arranged for by the Medical Director-General. Colonial candidates will have to pass a physical and test examination before a board of Naval Medical Officers on the station. Successful candidates immediately after passing the examination in London will receive commissions as Surgeons in the Royal Navy, and will undergo a course of practical instruction in Naval Hygiene, &c., at Haslar Hospital. Three prizes of the approximate value of £10 each will be awarded at the close of each *session at Haslar* to the students who have shown the greatest proficiency.

Surgeons on entry are only required to provide themselves with a pocket case of instruments, a stethoscope, and three clinical thermometers. All other instruments are provided at the public expense.

Promotion.

An Inspector-General of Hospitals and Fleets will be selected from amongst Deputy Inspectors-General who have in that rank three years' full pay service and who have not at any time declined foreign service except for reasons which the Lords Commissioners of the Admiralty regard as good and sufficient.

A Deputy Inspector-General of Hospitals and Fleets will be selected for ability and merit from amongst Fleet Surgeons.

(a) Subject to the approval of the Lords Commissioners of the Admiralty rank as Fleet Surgeon will be granted to Staff Surgeons at the expiration of eight years from the date of promotion to Staff Surgeon, provided they are recommended by the Medical Director-General and have not declined service except for reasons which in the opinion of the Lords Commissioners of the Admiralty are satisfactory. (b) Special promotions from the rank of Staff Surgeon to that of Fleet Surgeon will be made at their Lordships' discretion in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and will not exceed the rate of one in two years; the total number at any one time of Fleet Surgeons holding that rank by such special promotions will not exceed six.

(a) Rank as Staff Surgeon will be granted, subject to their Lordships' approval, to surgeons at the expiration of eight years from the date of entry, provided they are recommended by the Medical Director-General, and have passed such examination as may be required after completion of five years from the date of entry in the rank of surgeon. (b) Special promotions will be made at their Lordships' discretion to the rank of Staff Surgeon in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and not exceed the rate of one a year. The total number at any one time of Staff Surgeons holding that rank by such special promotions will not exceed eight. No officer will be so promoted unless he passes the examination prescribed for other surgeons, but in such a case the requirement of five years' time in rank of surgeon will be dispensed with. (c) When a surgeon's promotion to the rank of Staff Surgeon has been retarded by failure to pass the qualifying examination he will, should he pass and be promoted, be dealt with as follows. He will be granted the seniority as Staff Surgeon he would have received had he passed in ordinary course. He will reckon service for increase of full and half pay only from the date of appointment to full pay as Staff Surgeon. If on half pay, or if placed on half pay when promoted, he will receive the lowest rate of half pay of the new rank from the date of passing the qualifying examination. Where delay in passing the qualifying examination may be due to unavoidable circumstances special consideration will be given. (d) The seniority of surgeons on entry will be determined by the sum total of the marks they obtain at the London examination and those at the conclusion of the Haslar course and their names will then be placed in the official navy list, except in the case of candidates who hold, or are about to hold, a post as resident medical officer or surgical officer to a recognised civil hospital. These candidates will retain the position in the list which they obtained on entry, and when their period of service as resident officer is over, they will join the next Haslar course and will be required to obtain qualifying marks. Surgeons entered without competition will take seniority next after the last surgeon entered at the same time by competition. (e) The examination for promotion to the rank of staff surgeon will be held by the Examining Board, to which a naval medical officer will be attached to conduct the examination in naval hygiene. The subjects of examination will be in writing and will include medicine, surgery, pathology, general hygiene, naval hygiene. Earlier promotion to the rank of staff surgeon may be granted to those surgeons who, before entry, have held the post of legally qualified resident medical or surgical officer to a civil hospital of not less than 100 beds for a period of not less than six months, provided their conduct and professional abilities have been favourably reported on during the time they have served in the Navy. They may be granted from six months to one year's seniority, according to the time they have held their civil appointments, but in no case will more than one year's seniority be granted. This only applies to officers who enter by competition (Para. 4 (*f*)). A candidate who at the time of passing the examination for entry into the medical branch of the Royal Navy holds, or is about to hold, an appointment as resident medical or surgical officer in a recognised civil hospital, may be allowed to serve in such civil appointment provided that the period of such service after the date of entry into the Royal Navy does not exceed one year. Pay from naval funds will be withheld from officers while thus serving, but the time concerned will reckon for increase of full and half pay while on the active list, and retired pay or gratuity on retirement or withdrawal, except that no officer will be allowed to retire on a gratuity until he has completed four years' service exclusive of the time spent as resident medical or surgical officer. The elegibility of this appointment will also be decided by the Medical Director-General.

Full Pay and Allowances.

Rank.	Daily.	Yearly.
Surgeon—	£ s. d.	£ s. d.
On entry	0 14 0	255 10 0

The medical officers in charge of the following hospitals and sick quarters will be granted charge pay: Haslar, Plymouth, Chatham, Malta, Hong-Kong, Bermuda, Portland, Yarmouth, Haulbowline, Cape, Gibraltar, and Yokohama. The rate of charge pay will be as follows:—

	s. d.	
Inspectors-General...	10 0	a day.
Deputy Inspectors-General	7 6	,,
Fleet Surgeons of over 4 years' seniority	5 0	,,
Fleet Surgeons of under 4 years' seniority and Staff Surgeons	2 6	,,

The hospital allowances for naval medical officers at home and abroad, in lieu of provisions, for themselves and servants, and for fuel and lights, are as follows:—

—	At home.	Abroad.
	£	£
Deputy Inspectors-General	67	112
Fleet Surgeons and Staff Surgeons of over 4 years' seniority	53	112
Staff Surgeons of under 4 years' seniority and Surgeons...	39	108*

* Except at Malta, where the allowance will be £70, but servants will be provided at the public expense. These allowances are also granted to medical officers of marine divisions and dockyards.

An allowance of 5*s.* a day, in addition to full pay, is granted to the senior medical officer, being a Fleet or Staff Surgeon, of a flag-ship bearing the flag of a Commander-in-Chief. An allowance of 2*s.* 6*d.* a day is granted to the senior medical officer, being a Fleet or Staff Surgeon, of the ship bearing other flags or broad pendants. The following charge allowances may be granted to medical officers in charge of hospital ships: if above the rank of fleet surgeon, 5*s.* a day; and if of the rank of fleet surgeon or junior, 3*s.* 6*d.* a day. The Fleet and Staff Surgeons serving in the Admiralty and the Marine Rendezvous will be granted the Hospital allowance of £53 a year in addition to the usual lodging money. Medical officers conducting the course of instruction at Haslar Hospital will receive the following allowances: two senior officers employed upon this duty, £150 a year each; the junior officer assisting, £50 a year; and the junior officer instructing the Sick Berth Staff, £50 a year. The junior officer instructing the Sick Berth Staff at Plymouth, £50 a year. Medical officers employed elsewhere than at a hospital, and not victualled in kind, receive an allowance of 1*s.* 6*d.* a day in lieu of provisions, fuel, and lights. The travelling allowances, extra pay, lodging money, and compensation for losses are fixed for naval medical officers according to their relative rank in the service.

1890 do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised laboratory or laboratories, and must have studied for six months the duties of outdoor sanitary work under the medical officer of health of a county or large urban district or a medical officer of health who is also a teacher of Sanitary Science in a Medical School, or a sanitary staff officer of the Royal Army Medical Corps having charge of an Army Corps District or command. There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics, and (*c*) Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. James Robertson, solicitor, 54, George-square, and for Glasgow Mr. Alexander Duncan, LL.D., 242, St. Vincent-street.

Royal College of Physicians and Royal College of Surgeons in Ireland.—Stated examinations for the Diploma in Public Health are held in the months of February, May, July, and November. A special examination for the diploma may, at the discretion of the Committee of Management (except during the months of August and September), be obtained on payment of £15 15*s.*, in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination. Every candidate for the Diploma in Public Health must be a registered medical practitioner. (Candidates registered or entitled to be registered prior to January, 1890, are exempt from the rules as to study.) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. Each candidate must return his name to the secretary of the Committee of Management under the Conjoint Scheme two weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10*s.* The examination for the Diploma in State Medicine comprises the following subjects:—Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Sanitary Law, and Bacteriology. For further particulars apply to the Secretary, Committee of Management; Office, Royal College of Physicians, Dublin.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it is but little trouble to pass the special examinations. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than two years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanicalldepartment of a recognised dental hospital). The Denta Schools in London are the Royal Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals. A convenient arrangement by which the M.R.C.S., L.R.C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed the student should commence his mechanical training at a dental school or with a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to the date of registration as a dental student.) During his mechanical training the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital. (The foregoing constitute the First Examination.) Having entered the hospital the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology. At the completion of his second year of study the Dental Examination should be passed. The student should then devote his time to general studies and pass the Third Examination. When time permits it is advisable to attend the general hospital only until after the First and Second Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L.D.S. diploma. The best course, however, is entirely to finish the curriculum for the M.R.C.S. and L.R.C.P. and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

The Registration of Dental Students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies and of having received two years' instruction in mechanical dentistry. The two years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student, but no portion of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to be on the Register and no foreign qualifications are admitted.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination.—Before admission to this examination the candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry, Physics, and Practical Chemistry. The examination consists of these subjects and is identical with Part I. of the First Examination of the Examining Board in England. II. The First Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of mechanical dentistry, under the instruction (which may be taken prior to registration as a dental student) of a competent practitioner or under the direction of the superintendent of the mechanical department of a recognised dental hospital. 2. Of registration as a dental student by the General Medical Council. 3. Of having attended at a the production of vouchers at the end of the course. The medical officer will be required to produce separate certificates of efficient attendance in the *following*: (1) the medical and surgical practice of the hospital, including instruction in anæsthetics; (2) a course of operative surgery on the dead body; (3) a course of bacteriology; (4) a course of ophthalmic surgery, particular attention being paid to the diagnosis of errors of refraction; and (5) a practical course of skiagraphy. Relative rank is accorded to medical officers as laid down in the King's Regulations and Admiralty Instructions.

The Admiralty has made a considerable effort to make the Medical Service attractive to men of a good professional stamp. The new regulations promulgated on Oct. 31st, 1903, are of course included in the above account of the Naval Medical Service. By these regulations promotion was accelerated, special promotion in the lower grades was made possible in cases of distinguished service or conspicuous professional merit, and encouragement to enter the service, in the shape of earlier promotion, was given to men who have held resident posts in recognised hospitals. A feature of the latest regulations is the permission to withdraw at the end of four years with a gratuity of £500. The pay has been increased but, in respect of allowances, the medical officers of the navy, up to the senior ranks, are not as well off as those of the Royal Army Medical Corps. In spite of the steps taken by the Admiralty there is still much discontent among naval medical officers, and such discontent will exist until the medical officers are unhampered in the performance of their important work by the executive officers. The medical officers should have control over the sick bay staff in ships, and over nurses and other attendants in hospitals, and executive officers should no longer figure as presidents of "medical surveys." The authority of the Director-General must be made adequate. More care must also be taken that medical officers are assigned fitting cabin accommodation. To make the service thoroughly efficient the medical officers must be given authority and position commensurate with their responsibilities.

THE ARMY.

Consequent upon the issue of the Royal Warrant published in Army Orders dated July 1st, 1898, the Army Medical Staff and the Medical Staff Corps were formed into the Royal Army Medical Corps. Medical officers also have been placed as regards sick leave of absence on full pay, on the same footing as that laid down for regimental officers. By a Royal Warrant dated Nov. 10th, 1891, Art. 1203*b* of the Pay Warrant was revised by inserting the words "an officer of our Royal Army Medical Corps" after the words "combatant officer," thus giving medical officers an equal title with combatant officers to reckon time on half-pay towards retirement when the half-pay has been due to ill health contracted in the performance of military duty. Under the Royal Warrant of July, 1895, time on half-pay not exceeding a year may in similar circumstances also reckon towards promotion. In the New Royal Warrant it was announced that the late Queen had been pleased to approve of the following ranks for the officers of the Royal Army Medical Corps: Colonel, Lieutenant-Colonel, Major, Captain, and Lieutenant. The Warrant also states that the Medical Staff of the Army shall in future consist of Surgeon-Generals (ranking as Major-Generals). Officers of the Royal Army Medical Corps holding appointments in the Household Troops are to be borne as seconded officers on the establishment of the Royal Army Medical Corps.

REGULATIONS FOR ADMISSION TO THE ROYAL ARMY MEDICAL CORPS (PROMULGATED BY ARMY ORDERS DATED MAY 1ST, 1902).

A candidate for a commission in the Royal Army Medical Corps must be 21 years and not over 28 years of age at the date of the commencement of the entrance examination. He must, at the time of his appointment, be registered under the Medical Acts in force in the United Kingdom. A candidate must complete the subjoined form of application and declaration and submit it to the Director-General, A.M.S., in sufficient time to permit of reference to the medical school in which the candidate completed his course as a medical student.

*Application of a Candidate for a Commission in the Royal Army Medical Corps.**

1. Name in full ... ...
Address ... ...
3. Date of birth † ... ...
4. Qualifications ... ...
5. Academic and other distinctions ... ...
6. Name of the Dean or other responsible authority of the school in which the candidate completed his course as a medical student ... ...
7. Particulars of any commission or appointment held in the public services ... ...
8. Date of examination at which the candidate proposes to present himself ... ...

Declaration.

(N.B.—A mis-statement by the candidate will invalidate an subsequent appointment and cause forfeiture of all privileges for services rendered.)

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief and further:—

1. That I am a British subject of unmixed European blood.

2. That I am not, as far as I know, at present suffering from any mental or bodily infirmity, or physical imperfection or disability that is likely to preclude me from efficiently discharging the duties of an officer in any climate.

3. That I will fully reveal to the Medical Board, when physically examined, all circumstances within my knowledge that concern my health.

I also declare that my vision is good with either eye (with or without the aid of glasses as the case may be).

* All communications to be addressed to the Secretary, War Office, Whitehall, S.W.

† A certificate of registration of birth or other satisfactory evidence of age, such as a declaration made before a magistrate by one of his parents or guardians, giving the date of his birth, to be furnished.

The dean of the candidate's school will be requested by the Director-General to render a confidential report as to his character, conduct, professional ability, and fitness to hold a commission in the corps and to this report special importance will be attached. A candidate whose application is regarded as satisfactory will be directed to appear before the Director-General, Army Medical Service, a few days (usually on the fourth Thursday of the month) preceding the examination. The Director-General will decide if the candidate may be allowed to compete for a commission. If approved, he will then be examined as to his physical fitness by a board of medical officers. The following is the order of the examinations:—

1. A candidate for a commission in the Royal Army Medical Corps must be in good mental and bodily health and free from any physical defect likely to interfere with the efficient performance of military duty.

2. The attention of the board will be directed to the following points: (*a*) That the correlation of age, height, weight, and chest girth is equal or superior to that which is given in the following table:—

Physical Equivalents.

Age.	Height without shoes.	Chest.	
		Girth when expanded.	Range of expansion.
	Inches.		
21 and upwards.	62½ and under 65	35 inches.	2 inches.
	65 " 68	35½ "	2 "
	68 " 70	36 "	2 "
	70 " 72	36½ "	2½ "
	72 and upwards.	37 "	2½ "

(*b*) Measurement of height. The candidate will be placed against the standard with his feet together and the weight thrown on the heels and not on the toes or outside of the feet. He will stand erect without rigidity and with the heels, calves, buttocks, and shoulders touching the standard; the chin will be depressed to bring the vertex of the head level under the horizontal bar and the height will be noted in parts of an inch to eighths.

(*c*) Measurement of chest. The candidate will be made to stand erect with his feet together and to raise his hands above his head. The tape will be carefully adjusted round the chest with its posterior upper edge touching the inferior angles of the shoulder blades and its anterior lower edge the upper part of the nipples. The arms will then be lowered to hang loosely by the side and care will be taken that the shoulders are not thrown upwards or backwards so as to displace the tape.

(*d*) Weight. The candidate will also be weighed and his weight recorded in the proceedings of the Board.

The regulations regarding the examination of eyesight are as follows:—

1. If a candidate can read D.=6 at 6 metres (20 English feet) and D.=0·6 at any distance selected by himself, with each eye without glasses, he will be considered *fit*.

2. If a candidate can only read D.=24 at 6 metres (20 English feet) with each eye without glasses, his visual deficiency being due to faulty refraction which can be corrected by glasses which enable him to read D.=6 at 6 metres (20 English feet) with one eye, and D.=12, at the same distance with the other eye, and can also read D.=0·8 with each eye without glasses, at any distance selected by himself, he will be considered *fit*.

3. If a candidate can read D.=6 at 6 metres (20 English feet) with one eye, a higher defect than D.=24 will be accepted in the other; and if he can read D.=36 with the defective eye at the required distance, the defect being due to error in refraction which can be remedied by glasses so that he can read, at least, D.=12, he will be considered *fit*.

4. If a candidate cannot read D.=24 at 6 metres (20 English feet) with each eye without glasses, notwithstanding he can read D.=0·6, he will be considered *unfit*. The candidate must be able to read the

Examination on the ground of having passed the First and Second Triple Qualification Examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15*s.* payable for the dental diploma. The fee payable by candidates who began study before Oct. 1st, 1895, shall be £10 10*s.*, £4 4*s.* of which are payable on entering for the First Examination and £6 6*s.* on entering for the Second Examination.

Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics and the third Anatomy and Physiology. There is also an examination in Practical Dentistry conducted in a dental hospital.

Royal College of Surgeons in Ireland.—All information concerning the licence in Dental Surgery may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September. Primary Dental Examination.—Fee £10 10*s.*; for re-examination, if rejected, £5 5*s.* Every candidate[1] is required, before admission to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections, two courses of six months each; Lectures on Chemistry, six months; Lectures on Physiology, including Dental Physiology, six months; Practical Histology and Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical Instruction at a recognised general hospital for one year. The subjects of this examination are: (1) Physics;[2] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I. or students who have passed Primary Dental or Third Professional Examination of the College, £10 10*s.*; re-examination, £5 5*s.* Fees for Final Examination of all other candidates, £26 5*s.*; re-examination, £10 10*s.* Extra fee for Special Examination, £5 5*s.* Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following courses of lectures recognised by the College: Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a dental hospital recognised by the College or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination. Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the Workshop). Examinations for the Licence in Dentistry *sine curriculo*: The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

University of Birmingham.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10*s.*, is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Chemistry and Practical Chemistry, (*b*) Physics and Practical Physics, (*c*) Elementary Biology, (*d*) Anatomy and Practical Anatomy, and (*e*) Physiology and Practical Physiology. *B.* That he has attended the following courses and passed the class examinations in each of these subjects: (*f*) One Special Course of Lectures on Medicine, (*g*) One Special Course of Lectures on Surgery, and (*h*) Pathology and Bacteriology. *C.* That he has attended courses and passed the class examinations in: (*k*) Dental Histology and Patho-Histology, (*l*) Comparative Dental Anatomy, and (*m*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D.* 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which thesis shall be submitted to examiners to be nominated by the Dental Advisory Board. The degree will be awarded or withheld according to the report of these examiners.

The University also grants a diploma in Dental Surgery (L.D.S.) to candidates who have followed the prescribed regulations for the same.

University of Leeds.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the first examination, and to have completed such should he qualify, will be placed at the bottom of the list. Should he again fail in either examination his commission will not be confirmed. Illiteracy on the part of a candidate as evinced by inaccurate spelling, poor composition, or grammatical errors in the oral examination, at the entrance examination, or at the examinations undergone while on probation will be regarded as disqualifying for appointment.

---

[1] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[2] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

EXAMINATIONS FOR PROMOTION IN THE ROYAL ARMY MEDICAL CORPS.

These examinations are intended to test the progress and proficiency of officers in those branches of knowledge which are essential to their continued efficiency.

Lieutenant before Promotion to Captain.—(For Lieutenants appointed after March 31st, 1901.) This examination may be taken at any time after completing 18 months' service and will be held in the military district in which the officer is serving. The subjects of this examination, which are detailed in the King's Regulations, are as follows: (1) squad, company, and corps drills and exercises; (2) the duties of wardmasters and stewards in military hospitals, and the preparation of returns, accounts, and requisitions connected therewith; (3) duties of executive medical officers; and (4) military law.

Captains before Promotion to Major.—(For Captains promoted to that rank after July 27th, 1895.) Captains will be examined under the rules laid down in Paragraph 23 and will be eligible for acceleration in their promotion to the rank of Major under Article 352 of the Pay Warrant.

A Captain promoted to that rank in January, 1893, can gain the full acceleration. In all cases an officer who gains accelerated promotion will be placed for precedence after the last officer (whether subject to acceleration or not) promoted approximately 3, 6, 12, or 18 months before him.

This examination, which may be taken at any time after completing five years' service, will be held on the termination of a period of special study at such times and under such arrangements as the Director-General A.M.S. may determine. The examination will consist of written papers, essays, oral and practical examinations in the following subjects, which are detailed in the King's Regulations: (1) medicine; (2) surgery; (3) hygiene; (4) bacteriology and tropical disease; and (5) one special subject from the subjoined list to which additions may from time to time be made: (a) bacteriology and tropical diseases; (b) dental surgery; (c) dermatology, including venereal diseases; (d) midwifery and gynæcology; (e) operative surgery, advanced; (f) ophthalmology; (g) otology, including laryngology and rhinology; (h) psychological medicine; and (i) State medicine. Captains serving in that rank before July 27th, 1895, will be promoted under the old regulations contained in Appendix I., Regulations for Army Medical Services, and will not be eligible for acceleration.

Majors before Promotion to Lieutenant-Colonel (for Majors promoted to the rank after March 31st, 1895).—This examination, which may be taken at any time after three years in the rank of Major, will be held in the military district in which the officer is serving at times which will be duly notified. The subjects of this examination, which are detailed in the King's Regulations, are as follows: 1. Military law. 2. Army medical organisation in peace and war. 3. Sanitation of towns, camps, transports, and all places likely to be occupied by troops in peace and war; epidemiology, and the management of epidemics. 4. (a) Medical history of the more important campaigns and the lessons to be learnt therefrom; (b) a knowledge of the Army Medical Services of the more important Powers; and (c) the laws and customs of war, so far as they relate to the sick and wounded.

PAY.

The following shall be the rates of pay, additional pay, and charge pay of the Army Medical Staff and Royal Army Medical Corps:—

Army Medical Service.	Inclusive of all allowances except field and travelling allowances (yearly).
At Headquarters.	£
Director-General	2000
Deputy Director-General	1500
Assistant Director-General	850
Deputy Assistant Director-General	750
	Exclusive of allowances (daily).
At Other Stations.	£ s. d.
Surgeon-General	3 0 0
Colonel	2 5 0
Lieutenant-Colonel	1 10 0
Lieutenant-Colonel promoted to the rank on or after Jan. 9th, 1907, after three years as such	1 15 0
Major	1 3 6
After three years as such	1 6 0
Captain	0 15 6
After seven years' total full pay service	0 17 0
After ten years' total full pay service	1 1 0
Lieutenant on probation and Lieutenant	0 14 0
Adjutant of the Royal Army Medical Corps (Volunteers)	The pay of his rank.

A Captain of the Royal Army Medical Corps, holding the brevet rank of Major, shall receive pay at 2s. a day, in addition to the rates laid down.

Additional Pay.

An officer not serving on the Headquarters Staff appointed a member of the Advisory Board, £150 a year. An officer serving as secretary of the Advisory Board and Nursing Board, £100 a year. An officer under the rank of Lieutenant-Colonel holding an appointment as specialist, 2s. 6d. daily.

Charge Pay.

(a) An officer in charge of a general or other hospital, or of a division of a general hospital—

	Daily. s. d.
If in charge of at least 50 beds	2 6
" " 100 "	5 0
" " 200 "	7 6
" " 300 "	10 0
(b) Senior medical officer, Royal Arsenal, not exceeding	10 0
(c) Officer in command of the Depôt, Royal Army Medical Corps	5 0
(d) The Senior officer of the Army Medical Service with an army in the field— A rate to be fixed by the Secretary of State, according to the magnitude of the charge.	
(e) In a command abroad— The senior medical officer, if under the substantive rank of colonel, if the number of soldiers is 1500 or upwards	5 0

Extra-duty Pay.

An officer of the Royal Army Medical Corps, appointed to act as adjutant or quartermaster of the Royal Army Medical Corps (Militia) during preliminary drill or training shall receive extra-duty pay at the following rates:—

	Daily. s. d.
Acting Adjutant	2 6
Acting Quartermaster	2 0

Reserve of Officers.

An officer of our Royal Army Medical Corps with at least three, but not more than six, years' service may be permitted by our Army Council to become an Army Reserve Officer for a period of seven years, and while so serving he shall receive pay at the rate of £25 a year. With the sanction of our Army Council such officer may be allowed to return to the active list, and if the period he has been in our Reserve of Officers amounts to at least one year, and not more than three years, he shall be allowed to reckon one-third of such period towards promotion, gratuity, and pension.

Seconded Officers.

A Lieutenant on probation who at the time of passing the examination for admission to the Royal Army Medical Corps holds, or is about to hold, a resident appointment in a recognised civil hospital may be seconded for a period not exceeding one year during which he holds the appointment. While seconded he shall not receive pay from army funds, but his service shall reckon towards promotion, increase of pay, gratuity, and pension.

PROMOTION.

Every promotion of a medical or departmental officer shall be made with the approval of our Secretary of State. Promotion by selection shall be given on the ground of ability and merit, due consideration being given, however, to length of efficient service.

An officer shall be eligible for promotion to the rank of Captain on the completion of three and a half years' service, and to the rank of Major on the completion of 12 years' service, provided that in each case he has previously qualified in such manner as may be prescribed by the Army Council.

Promotion to the rank of Lieutenant-Colonel to complete an establishment shall be made by selection from Majors who have qualified in such manner as may be prescribed by the Army Council.

If an officer has passed with distinction the examination qualifying for promotion to the rank of Major, the period of service required to render him eligible for the rank of Major or Lieutenant-Colonel may be reduced as follows:—

	Months.
If he obtained a "special certificate"	18
" passed in the 1st Class	12
" " " 2nd "	6
" " " 3rd "	3

Promotion to the rank of Colonel to complete an establishment shall be made by selection from Lieutenant-Colonels and from Lieutenant-Colonels or Surgeon-Lieutenant-Colonels of the Household Troops specially recommended to the Army Council for distinguished service in the field. Promotion to the rank of Surgeon-General shall be made by selection from Colonels. A Colonel may also be promoted to the rank of Surgeon-General for distinguished service in the field. In cases of distinguished service in the field a departmental officer may, with the concurrence of the Lords Commissioners of the Treasury, be promoted from any rank or class to the next above it and shall, if promoted to a rank or class having a fixed establishment, remain supernumerary in such rank or class until the occurrence of the vacancy to which in the ordinary course he would have been promoted. An officer of the Royal Army Medical Corps is eligible for promotion to brevet rank. A Captain after at least 6 years' service, a Major or Lieutenant-Colonel, may be promoted to the next higher rank by brevet for distinguished service in the field or for distinguished service of an exceptional nature other than in the field. If the officer dies before the date on which the notification of his promotion for distinguished service in the field appears in the *London Gazette* the promotion shall bear the date which it would have borne had the officer not died. Distinction in original investigation or research may, in the case of officers of the Royal Army Medical Corps, be regarded as "distinguished service of an exceptional nature other than in the field." An officer who does not qualify for promotion to the rank of Captain or Major within the periods specified shall be placed on a special list with pay equal to half pay until the date of the next succeeding examination, provided a period of eight months is not thereby exceeded. An officer who may in the opinion of the Army Council have been prevented, in very special circumstances, from qualifying for promotion, or who, having failed and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. A prize of the value of 5 guineas is given by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. Consulting Physician: Sir Richard Douglas Powell, Bart. Consulting Dental Surgeons: Mr. T. Arnold Rogers, Mr. Morton Smale, and Mr. C. S. Tomes, F.R.S. Dental Surgeons: Mr. J. F. Colyer, Mr. C. F. Rilot, Mr. H. Lloyd Williams, Mr. W. H. Dolamore, Mr. G. Hern, and Mr. J. G. Turner. Assistant Dental Surgeons: Mr. N. G. Bennett, Mr. D. P. Gabell, Mr. A. Hopewell Smith, Mr. H. Austen, and Mr. R. McKay. Anæsthetists: Dr. Dudley Buxton, Dr. R. J. Probyn-Williams, and Mr. H. Hilliard. Demonstrators: Mr. A. L. Whitehouse, Mr. L. C. Ball, Mr. J. G. Atkinson Fairbank, Mr. F. Butler, and Mr. G. H. Curtis. Lecturers:—Dental Anatomy and Physiology (Human and Comparative): Mr. A. Hopewell Smith. Dental Surgery and Pathology: Mr. J. G. Turner. Mechanical Dentistry: Mr. W. J. May. Metallurgy in its application to Dental Purposes: Mr. P. Ellis Richards. Dental Bacteriology: Mr. Howard Mummery. Dental Materia Medica: Mr. H. A. Austen. During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. Fee for two years' hospital practice required by the curriculum, including lectures, £53 3s. in one payment, or £55 13s. in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £60. Both hospitals can be attended simultaneously. The fee for the instruction in Mechanical Dentistry and the two years' hospital practice required by the curriculum is £150 if paid in one instalment, or 150 guineas if paid in three equal instalments. The fee for tuition in Mechanical Dentistry is 50 guineas per annum; for one year's hospital practice £21. The Dean attends at the hospital every Wednesday morning from 9 to 10.30, or he can be seen at other times by appointment. Letters to be addressed—The Dean, 32, Leicester-square, "to be forwarded."

National Dental Hospital and College.—Corner of Great Portland and Devonshire-streets, W.—Consulting Physician: Sir Victor Horsley. Consulting Dental Surgeon: Mr. Sidney Spokes. Visiting Physician: Dr. James Maughan. Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H. Weiss, Mr. K. W. Goadby, Mr. W. Weiss, Mr. Rushton, Mr. S. F. Rose, and Mr. A. E. Relph. Assistant Dental Surgeons: Mr. H. R. Pring, Mr. H. Creemer Cooper, Mr. H. W. Turner, and Dr. J. W. Pare. Anæsthetists: Mr. H. P. Noble, Mr. C. J. Ogle, Mr. Vivian B. Orr, Dr. J. Maughan, Dr. Cecil Hughes, and Mr. R. E. Delbruck. Lecturers (winter), Dental Anatomy and Physiology: Dr. J. W. Pare, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Dental Metallurgy: Mr. Hugh Candy, Tuesdays, 5 P.M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Wednesdays, 5.30 P.M., in May, June, and July. Dental Materia Medica: Mr. Charles W. Glassington, Tuesdays, 6 P.M., October, November, and December. Summer—Dental. Surgery and Pathology, Mr. H. J. Relph, Thursdays, 5 P.M., during January, February, and March. Bacteriology of the Mouth: Mr. K. W. Goadby, Tuesdays, 4 P.M., during May, June, and July. Practical courses to comply with the R.C.S. curriculum are also held. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for 50 chairs. Dresserships in the extraction and stopping rooms are re-arranged every three months. Two Entrance Exhibitions, of the value of £40 and £20, are open for competition. Prizes are open for competition at the end of each course of lectures. Certificates of honour are also open in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the mostr meritorious student; and the Ash Prize, value £3 3s., foe a Thesis on a subject in Dental Surgery. Total fee for th. Special Lectures and Hospital Practice required, 40 guineasl A composition fee covering the two years' mechanica pupilage and the two years' hospital practice required by the Royal College of Surgeons, £120. Single Courses: Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Mechanics, Dental Metallurgy, Bacteriology of the Mouth, Dental Materia Medica, Demonstration of Dental Mechanics, £5 5s. each. Hospital Practice to registered practitioners by special permission of Committee, 12 months, £15 15s. The Committee also consider applications from medical men who may desire to attend the Anæsthetic Room for a course of instruction in Nitrous Oxide administration. Information respecting the Hospital Practice and the College may be obtained from the Dean; Mr. Sidney Spokes, who attends at the Hospital, Great Portland-street, on Tuesday mornings.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. *The Extraction Rooms:* Patients are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required. *The Conservation Room:* This room is open from 9 A.M. till 5 P.M. There are 55 Morrison chairs, each fitted with a saliva ejector, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at this hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the special lectures and practice of the Dental Department and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Two Entrance Scholarships in Dental Mechanics of the value of £20 each are offered for competition annually, one in September and one in April, and prizes of the aggregate value of £35 are awarded for general proficiency and skill in Practical Dentistry. Dental students are eligible for admission to the Residential College and enjoy the other social privileges of students in the Medical School.

Staff. — Dental Surgeons: Mr. W. A. Maggs, Mr. Wynne Rouw, Mr. H. L. Pillin, and Mr. M. F. Hopson. Assistant Dental Surgeons: Mr. J. B. Parfitt and Mr. J. L. Payne. Demonstrators of Practical Dentistry: Mr. E. B. Dowsett, Mr. F. J. Pearce, Mr. J. E. Spiller, Mr. H. P. Aubrey, and Mr. H. Chapman. Anæsthetists: Dr. H. F. Lancaster, Mr. C. J. Ogle, Mr. P. Turner, Mr. A. R. Thompson, Mr. W. M. Mollison, and Mr. R. Davies-Colley. Lecturers.—Dental Surgery and Pathology: Mr. Wynne Rouw. Dental Anatomy and Physiology: Mr. Maggs. Operative Dental Surgery: Mr. Parfitt. Dental Mechanics: Mr. Payne. Practical Dental Mechanics: Mr. Pillin. Dental Materia Medica: Dr. A. P. Beddard. Dental Bacteriology: Dr. Eyre. Dental Microscopy: Mr. Ryffel and Mr. Laidlaw. Metallurgy: Dr. J. Wade. Practical Dental Metallurgy: Mr. Hopson. Curator of Dental Museum: Mr. Dowsett. Dean: Dr. Eason.

London Hospital.—Mr. Dolamore and Mr. Farmer give practical instruction during the winter and summer sessions on Tuesdays and Thursdays at 11 A.M. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department. A class for special instruction in filling teeth will be formed each term. Dental patients in 1906, 9298.

PROVINCIAL.

University College, Bristol.—Laboratories for instruction in Mechanical Dentistry and in Dental Metallurgy have been established in the College and dental students can enter for the full curriculum at Bristol. The Lectures are delivered at the College. Practical instruction is given at the *General Hospital Royal Infirmary* by Mr. Ackland and at the by Mr. Genge, both institutions being recognised by the Dental Board of the Royal College of Surgeons of England. Full information may be obtained of the Dean of the Medical

SERVICE ON THE WEST COAST OF AFRICA.

An officer volunteering for, or ordered to, the West Coast of Africa shall receive double pay while actually serving on the coast, and for any time spent at Madeira or the Canary Islands on sick leave, or on ordinary leave not exceeding 61 days in a year.

For each year's service on the coast a medical officer shall be entitled to full pay during 183 days' leave at home, and for every additional period beyond a year he shall have a proportionate extension of full pay during leave.

Each year or portion of a year served on the West Coast of Africa by an officer of the Royal Army Medical Corps shall reckon double towards voluntary retirement or retired pay, provided that he has served 12 months on the coast. In ordinary cases the 12 months may be made up of two separate periods of not less than six months each; and if an officer leaves the coast on account of sickness he may reckon any period of service on the coast, however short, in order to make up the 12 months' coast service which is required to entitle him to count his service double. Except when the officer has been invalided, any broken period, if amounting to less than six months' of service on the coast, and leave on full pay, shall not reckon double under this article.

WIDOWS' PENSIONS.

Widows' pensions and compassionate allowances for children and other relatives of deceased officers are given under certain conditions specified in the Royal Warrant for Pay and Promotion. There is also an Army Medical Officers' Widows' Annuity Fund on mutual assurance principles.

ROYAL ARMY MEDICAL CORPS IN INDIA.

Under the Indian commands reorganisation scheme it is ordered that: (*a*) The appointments of principal medical officer, personal assistant to the principal medical officer, sanitary officer, and staff officer, Army Bearer Corps, in each command, and of sanitary officer and staff officer, Army Bearer Corps, in the Secunderabad Division and Burma, will be abolished. (*b*) The principal medical officers of the three divisions will be surgeon-generals, their pay being fixed at 2200 rupees *per mensem*, consolidated. (*c*) Two temporary administrative posts will be created, each to be held by a colonel—viz.: one for the Allahabad and the second for the Secunderabad brigades, infantry and cavalry. (*d*) A colonel will be appointed deputy to the principal medical officer of His Majesty's forces in India, his pay being fixed at 1800 rupees a month, consolidated. (*e*) A sanitary officer will be appointed in each office of the nine divisions and in Burma, the staff pay being fixed at 300 rupees per mensem. (*f*) A staff officer for medical mobilisation stores will be appointed in each of the nine divisions (excluding Burma), the staff pay being fixed at 300 rupees per mensem. (*g*) Owing to the above changes the establishments of medical services in India will be reduced by a number of officers corresponding to the number of cadre appointments abolished. (*h*) Existing lady superintendents will, under the orders of the principal medical officer of His Majesty's forces in India, be distributed to the charge of four circles, as follows: First Circle, comprising Peshawur, Rawul Pindi, and Lahore Divisions; Second Circle, comprising Meerut and Lucknow Divisions; Third Circle, comprising Quetta, Mhow, and Poona Divisions; Fourth Circle, comprising Secunderabad Division and Burma. (*i*) Orders regarding the disposal of clerks and establishments of the medical division officers at command headquarters will be issued by the principal medical officer, His Majesty's forces in India.

REGULATIONS FOR ADMISSION TO THE ARMY MEDICAL RESERVE.

CANDIDATES FOR COMMISSIONS.

Qualifications.

1. A candidate for a commission in the Army Medical Reserve must not be over 30 years of age at the date of his appointment.

2. He must be registered under the Medical Acts in force in the United Kingdom at the time of his appointment.

3. He must complete the form of application and declaration shown hereafter.

Appointment and Promotion.

4. If his application is approved the candidate will be directed to present himself at a military station convenient to his place of residence, in order that he may be examined by an officer of the Royal Army Medical Corps as to his physical fitness for a commission.

5. The standard of physique required will be that laid down for candidates for the Royal Army Medical Corps.

6. If selected, he will be appointed a Lieutenant on probation, and will be required to undergo a course of instruction at the Depôt, Royal Army Medical Corps, at Aldershot, for two months. Classes will begin about 1st February, 1st July, and 1st September in each year, and a candidate will, as far as possible, be permitted to select the class most convenient to him. At the conclusion of this course he will be examined as to his fitness to have his commission confirmed.

7. Commissions will date from time of joining the class of instruction at the Depôt.

8. Lieutenants when appointed will be required to provide the following articles of uniform, towards the expenses of which an allowance of £5 will be issued:—

Cap, field service, khaki.
Frock, khaki.
Pants, khaki, 1 pair.
Puttees, khaki, 1 pair.
Boots, regulation, brown, 1 pair.
Sam Browne *belt and sword.*

9. Before becoming eligible for promotion to Captain, a Lieutenant will be required to undergo a second course of instruction for one month, at the conclusion of which he will be examined as *to his fitness* for such promotion.

Conditions of Service.

10. Officers of the Army Medical Reserve will be liable to be called to army service at home or abroad at a time of emergency.

11. Officers of the Army Medical Reserve who are willing to offer their services in times of peace will be considered for employment with troops in the locality in which they reside.

12. *Extracts from the Royal Warrant for Pay and Promotion.*

The following extracts are given for the information of candidates:—

Commissions as Lieutenants in Our Army Medical Reserve may be given to persons, not over 30 years of age, who may be duly qualified under regulations approved by Our Army Council. (Art. 654.)

The ranks of officers of Our Army Medical Reserve shall be those of Captain and Lieutenant, and the total period of service in the Reserve shall be limited to seven years. On the completion of three and a half years' service a Lieutenant shall be eligible for promotion to the rank of Captain, if recommended for that rank. (Art. 655.)

Appointments to commissions will be made on probation, and persons so appointed will undergo an initial training of two months, on the expiration of which, should their work and conduct be considered satisfactory, their commissions will be confirmed. Officers of the Reserve before promotion to the rank of Captain shall fulfil such conditions as Our Army Council may determine, and shall undergo one month's further training. (Art. 656.)

When called to army service, or while undergoing training, officers of the Reserve shall receive the pay and allowances of officers of similar rank in the Royal Army Medical Corps. After the first year's service an officer shall, in addition to any such pay and allowances for days of actual service, receive pay at the rate of £20 a year. This rate shall be increased to £25 a year if the Officer is promoted to the rank of Captain. (Art. 657.)

Officers of the Army Medical Reserve will be subject to the general regulations applicable to Army Reserve Officers as laid down in the following extracts from the Pay Warrant, so far as such regulations do not conflict with those laid down in the foregoing Articles.

Officers who volunteer for service in the Reserve of Officers, and whose services are accepted, shall receive commissions from Us as officers in Our Land Forces. (Art. 660.)

An Army Reserve Officer shall report himself at the commencement *of each year, in writing, to Our Army Council.* Should he fail to do so he shall (unless he is an officer retired from Our Regular Forces, with liability for further service in case of emergency) be removed from Our Reserve of Officers at the end of the year in which he fails to report himself. (Art. 662.)

An Army Reserve Officer shall, if his services have been of a special character and if recommended to Us by Our Army Council, be eligible on retirement for a step of substantive or honorary rank, or of brevet rank for distinguished service. (Art. 664.)

An Army Reserve Officer may, with his own consent and the sanction of Our Army Council, be employed on Army Service at any time. (Art. 667.)

Application of a Candidate for a Commission in the Army Medical Reserve.

1. Name in full ... ...
2. Address .. ..
3. Date of birth* ... ...
4. Qualifications ... ...
5. Academic and other distinctions ....
6. Medical school in which the candidate completed his course as a medical student ... ...
7. Name of a person of position and responsibility who can be referred to as to candidate's character, conduct, and fitness to hold His Majesty's Commission ... ...
8. Particulars of any commission or any appointment held since qualifying ... ...

Declaration.

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief, and further—

1. That I am a British subject of unmixed European blood.

2. That I am not, as far as I know, at present suffering from any mental or bodily infirmity, or physical *imperfection or disability* that is likely to preclude me from efficiently discharging the duties of an officer in any climate.

3. *That I will* fully reveal when physically examined all circumstances within my knowledge that concern my health.

I also declare that my vision is good with either eye (with or without the aid of glasses as the case may be).

Signature..............................

Date..............................

(N.B.—A misstatement by the candidate will invalidate any subsequent appointment and cause forfeiture of all privileges for services rendered.)

All communications to be addressed to the Secretary, London, S.W.

* A certificate of registration of birth or other satisfactory evidence of age, such as a declaration made before a magistrate by one of his parents or guardians, giving the date of his birth, to be furnished.

INDIAN MEDICAL SERVICE.

The grades of officers in the Indian Medical Service are the same as those of the Army Medical Service and Royal Army Medical Corps. The Director-General will rank either

Newman, Dr. A. Wellesley Harris, Dr. E. J. Steegmann, Dr. E. Petronell Manby, Professor H. R. Kenwood, Dr. P. Boobbyer, Dr. James Kerr, Colonel J. Lane Notter, R.A.M.C., Mr. J. Osborne Smith, Mr. W. C. Tyndale, M.Inst.C.E., Mr. A. Saxon Snell, F.R.I.B.A., Mr. J. E. Worth, M.Inst.C.E., Mr. J. Wright Clarke, Mr. W. Hunting, F.R.C.V.S., Mr. James King, M.R.C.V.S. For members the annual subscription is £2 2*s.* and for associates £1 1*s.*, but members and associates holding certain qualifications only pay half the ordinary rate of subscription.

THE ROYAL INSTITUTE OF PUBLIC HEALTH.—The Royal Institute of Public Health, 37, Russell-square, W.C., was founded in the year 1886 with the object of obtaining the registration of public health diplomas and the further statutory requirement that all medical officers of health should possess such a qualification. In 1905 the Fellows and members of the Institute, now numbering nearly 2000, decided to create a central public health institution in London and have erected bacteriological, parasitological, and chemical laboratories in which researches of a public-health character are undertaken for municipal and other authorities and for private medical practitioners and the necessary training for obtaining public health diplomas is provided, together with a library, lecture room, and common room. The Royal Institute of Public Health is recognised by the University of London as a public educational institution, and its course of instruction for the diploma by the universities and other examining bodies of the United Kingdom. The Institute is under the patronage of His Majesty the King, and the Right Hon. Lord Strathcona and Mount Royal is President. The teaching staff consists of—the Principal, Professor William R. Smith, M.D., F.R.S.E.; lecturer on parasitology, Dr. Louis W. Sambon; demonstrator of chemistry, Mr. C. E. Harris, Ph.D.; demonstrator of bacteriology, Dr. Carl Prausnitz. Occasional lectures are given by eminent sanitarians. The Harben lecturer for 1907 was Paul Ehrlich of the Königliches Institut für Experimentelle Therapie, Frankfort, whose lectures were published in THE LANCET of June 15th, July 6th, and August 10th, and the Harben lecturer for 1908 is Professor G. H. F. Nuttall, M.D., F.R.S., University of Cambridge.

OPENING OF THE LONDON MEDICAL SCHOOLS.

WINTER SESSION 1907–08.

St. Bartholomew's Hospital.—The session will commence on Oct. 1st next. The old students' dinner will be held in the Great Hall in the evening of the same day at 6 30 for 7 P.M., when Mr. Harrison Cripps will preside. The new buildings, comprising the casualty, out-patient, and special departments, will be opened for inspection before and after the dinner.

Charing Cross.—The winter session will be opened on Oct. 1st by the annual distribution of prizes and an address to the students in the out-patients' hall at the hospital at 4 P.M. by the Right Hon. the Earl of Kilmorey, K P The dinner of the past and present students will take place on the evening of the same day.

St. George's Hospital.—The session will open on Oct. 1st, when Dr. W. Ewart, senior physician to the hospital, will deliver the inaugural address on "*Res Medica, Res Publica*": the Profession of Medicine, its Future Work and Wages, in the large theatre of the Medical School at 4 P.M. The annual dinner will take place in the evening of the same day, at 7 P.M., at the Hotel Metropole, when Sir Herbert M. Ellis, K.C.B., Director-General of the Medical Department of the Royal Navy, will preside.

Guy's Hospital.—The session will begin on Oct. 1st. The first meeting of the Guy's Hospital Physical Society will be held on Friday, Oct. 4th; when Dr. G. A. Gibson will read a paper entitled "Past and Present." Sir Samuel Wilks will occupy the chair.

King's College.—The opening of the winter session will take place on Oct. 1st, when the introductory address on Some Observations on the Present State of Medical Education in London will be delivered by Dr. W. H. Allchin, consulting physician to the Westminster Hospital. On the evening of the same day the annual old students' dinner will be held, at 7 P.M., at the Hotel Cecil, Strand, Dr. J. B. Bradbury, Downing professor of medicine, Cambridge, presiding. Tickets, one guinea, may be obtained from Sir Hugh R. Beevor, Bart., 17, Wimpole-street, London, W.

London Hospital.—The old students' dinner will be held o Tuesday, Oct. 1st, at 7.30 P.M., at the Savoy Hotel, Victori Embankment, when Mr. Frederic S. Eve will preside. Th price of the tickets will be half-a guinea each, exclusive wine (honorary secretaries, Dr. Henry Russell Andrew 7, Wimpole-street, London, W., Mr. Hunter Tod, 111, Harle street, London, W.). The afternoon reception by the sta will take place in the library of the medical college fro 3 to 5 o'clock.

Middlesex Hospital.—The session will begin on Oct. 1st 3 P.M., when Mr. A. G. R. Foulerton will give an intr ductory address on the Development of Preventive Medici in Relation to the Welfare of the State, after which t prizes gained during the previous year will be distribut by Mr. Henry Morris. The annual dinner of the past a present students and their friends will take place at t Trocadéro the same evening at 7 o'clock precisely; M Andrew Clark will preside.

St. Thomas's Hospital.—The session will open on Oct. 1 The old students' dinner will take place at the Victoria Ha Hotel Cecil, on Oct. 1st, at 7 o'clock for 7.30, when D Theodore Dyke Acland will preside.

University College Hospital Medical School.—The sess will commence on Oct. 2nd, at 3 P.M., when the Dea report will be read. The introductory address w be delivered by Sir Richard Douglas Powell, who w afterwards distribute the prizes and unveil the memori to the late Dr. G. V. Poore, physician to University Coll Hospital, and the late Mr. Christopher Heath, surgeon University College Hospital and formerly President of t Royal College of Surgeons of England. The old studen dinner will be held in the library of the school during t evening of the same day at 6.30 for 7 P.M., Sir William Gowers presiding. Tickets may be obtained from t dinner secretaries, Mr. Raymond Johnson, 11, Wimpo street, London, W., and Dr. C. Bolton, 16, Devonshire-stre London, W.

Westminster Hospital.—The winter session will begin Oct. 1st. The annual dinner will take place on Oct. 3rd the Trocadéro; Mr. Alfred H. Tubby will preside. T secretary of the dinner is Mr. E. Rock Carling, 14, Mandevil place, London, W.

London (Royal Free Hospital) School of Medicine Women.—The introductory address will be given by M Sarah Gray at the Medical School on Oct. 1st, at 4 P.M.

Seamen's Hospital Society (Dreadnought Hospital Clinical School).—The session will begin on Oct. 21st, w the inaugural address will be delivered at the Lon School of Tropical Medicine by Sir Lauder Brunt F.R.S., at 3.30 P.M. Sir Lauder Brunton will be the gu of the teachers and students of the School at the din which will be held on the same evening.

Pharmaceutical Society of Great Britain.—The sess will open on Sept. 30th, when Professor R. Meldola w deliver the inaugural address on the Scientific Training the Pharmacist, at 3 o'clock.

THE HEALTH OF GLASGOW.—According to report recently issued the death-rate in Glasgow for 1 increased 0·5 per 1000 over the rate for 1905. Whatever t increase be due to it is satisfactory to note that neit respiratory diseases nor the zymotic class of ailments responsible. During 1906 there were 991 fewer infecti disease cases registered than in 1905, the principal dimi tion being in measles. Against that, however, seve increases have to be recorded, the most import being 205 cases of cerebro-spinal fever, for whi if they did occur, there was no specific name the previous year. The distribution of the ca of this disease has been extremely puzzling, so of the most congested wards in the city having escaped m more lightly than others. It is satisfactory to note t there were only ten known cases of typhus fever 1906. This is remarkable when one considers that the city there are 20,792 houses, from 6 to 8 per cent. which are constantly overcrowded; in fact, under such c ditions as are known to exist at night in some localities, i well-nigh incredible that the disease should have been conspicuous by its absence. Throughout the city there w 65 more deaths from phthisis than in the previous ye Cases of small-pox have been almost entirely absent, th being notified during the year as against four in the precedi year.

The prizes formerly open to competition in the old Army Medical School at Netley have been transferred to the Medical Staff College in London and at present they are re-distributed as follows (but the arrangements as regards all the prizes are to be re-made now that all the course is to be attended in London): The Herbert Prize, the Parkes Memorial Bronze Medal, and the de Chaumont prize are now set aside to be competed for by the lieutenants-on-probation of the Royal Army Medical Corps, while the Webb prize and the Pathology prize are competed for by the young officers of both services. The two Montefiore prizes are open to the competition of the lieutenants-on-probation of the Indian Medical Service, and the Martin Memorial Gold Medal is competed for by the lieutenants-on-probation for the same service after the course in Military Medicine. The Maclean prize was withdrawn on the abolition of the Army Medical School and foundation of the Medical Staff College. The Herbert Prize of £20 is awarded to the lieutenant-on-probation who has obtained the highest number of marks at the Staff College examination in London; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in hygiene; the de Chaumont prize of books to the one who takes second place in Hygiene; the Montefiore Medal and £21 are awarded for Military Surgery; the Montefiore Second Prize, a cheque to the lieutenant-on-probation who obtains the second highest number of marks in this branch; a prize of books is given for the highest number of marks gained in Pathology; and the Marshall Webb prize of £5 and a bronze medal is awarded for Hospital Administration.

At the close of the session those lieutenants-on-probation who have obtained one-third of the possible total of marks and have satisfied the authorities that they possess the necessary skill, knowledge, and character for permanent appointment are recommended for commissions as Lieutenants in the Indian Medical Service.[4]

Officers on appointment are, when possible, provided with passage to India by troop transport; when such accommodation is not available passage at the public expense is provided by steamer, or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2*s.* a day. This payment does not include the cost of liquors, which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of terminating his course of instruction, or within 14 days of the termination of his hospital appointment if the Secretary of State has permitted him to hold one will be considered as having forfeited his commission unless special circumstances shall justify a departure from this regulation.

APPENDIX I.

CERTIFICATES OF AGE AND NATIONALITY REQUIRED BY NATIVES OF INDIA.

MEDICAL DEPARTMENT.

The Governor-General in Council is pleased to publish the following rules under which certificates of age and nationality will be issued to natives of India who are candidates for the examinations for the Indian Medical Service held in England.—

General Rules applicable to all Candidates.

A candidate for admission to compete in England for the Indian Medical Service is required before leaving India to obtain a certificate of age and nationality, signed, should he be a resident in British India, by the Secretary to the Government of the Province or the Commissioner of the Division within which his family resides, or, should he reside in a native State, by the highest Political Officer accredited to the State in which his family resides.

Note.—In the case of a candidate who has proceeded to England without obtaining a certificate the certificate may be granted to his father or guardian, provided that the latter produces the requisite evidence, and, when making the application, states when the candidate went to England and where he has been residing during his stay in that country.

In order to obtain a certificate, a candidate is required, if resident in British India, to prove the date and place of his birth before the magistrate of the district in which his family resides, or, if resident in a native State, before the Political Officer of the State in which his family resides.

A candidate must, if resident in British India, signify to the Secretary to the Government of the Province or the Commissioner of the Division in which his family resides his desire to compete not less than three months before the date on which he proposes to go to England. If resident within a Native State, he must signify his desire in like manner to the highest Political Officer accredited to the State within which his family resides.

The officer to whom the application is made shall forward it for the purpose of inquiry to the Magistrate of the district or Political Officer of the State in which the applicant's family resides.

The Magistrate or Political Officer to whom such application has been forwarded shall call upon the candidate to appear and give evidence of the date and place of his birth and of his nationality within one month. He will carefully examine into the value of the evidence given and forward a summary of it, with certified copies of all documents tendered, and his comments and opinion, to the officer who forwarded the application to him for inquiry.

The documentary evidence which a candidate may be expected to produce comprises—(*a*) the horoscope; (*b*) family books; (*c*) tradesmen's account books showing entries relating to the birth; (*d*) the record of admission in the registers of the school in which the candidate was educated and the record of the candidate's age at various periodical school examinations; and (*e*) if the candidate is matriculated a certified copy of his application to the Registrar.

Oral testimony of persons acquainted with the candidate's family or otherwise able to give relevant evidence, will also be taken; and the candidate is required to comply to the best of his power with any requisition the Magistrate or Political Officer, as the case may be, may make in order to clear up any doubt as to the purport of the documentary proof.

Any declaration of age made after the application of these rules on the occasion of seeking admission to any university examination, educational institution, or Government office, or otherwise recorded in a formal and deliberate manner, will be taken as conclusive evidence in disproof of the subsequent assertion by the same person that he is of different age to that so declared or recorded.

Rules to apply to Candidates Born in His Majesty's Dominions.

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, shall be satisfied by the papers submitted that the candidate has stated the date and place of his birth correctly, he will issue a certificate declaring that the candidate has submitted the proofs of his birth to the Magistrate of the district or the Political Officer of the State, as the case may be, and has satisfied him that he was actually born on or about the dates stated by him, viz., the   day of   , at   , a place within His Majesty's Dominions. The nature of the evidence produced by the candidate must be stated in the certificate, which shall be given in the following form:—

> I hereby certify that   , who is a candidate for the Indian Medical Service, has submitted the proofs of his birth detailed below, and has satisfactorily shown that he was actually born on or about the date stated, viz., the   day of   , at   , a place within His Majesty's Dominions.
>
> (Here enter details.)

* * * * * * *

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, finds reason to disbelieve that the candidate was born on the day or at the place asserted by him, the certificate will be refused and the candidate will be unable to obtain admission to the competitive examination for the Indian Medical Service.

Where the date and place of the birth have been formally registered in a register kept by any public officer in British India, an extract from the register, duly certified by the proper official, shall be accepted as sufficient proof of the date and place of the birth.

Rules to apply to Candidates not Born within His Majesty's Dominions.

In addition to the particulars required by Rule 2, a candidate not born in His Majesty's Dominions must also prove that he is the son or grandson of a person born in those dominions.

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, shall be satisfied by the papers submitted that the candidate has stated the date and place of his birth correctly, and has established the fact that, though born without the limits of His Majesty's dominions, he is the son or grandson of a person born in those dominions, he will issue a certificate in the following form, stating the nature of the evidence produced regarding the candidate's birth:—

> I hereby certify that   , who is a candidate for the Indian Medical Service, has submitted the proofs of his birth detailed below and has satisfactorily shown that he was actually born on or about the date stated, viz., the   day of   , and that he was born at   , a place without His Majesty's Dominions, but that he is the $\frac{\text{son}}{\text{grandson}}$ of a person born in those dominions.
>
> (Here enter details.)

* * * * * * *

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, finds reason to doubt that the candidate was born on the day asserted scientific means of estimating the results of treatment. More recently the attention thus drawn to the cytology of the blood has been the means of starting the cytological investigation of other fluids which bids fair to afford a means of early diagnosis of some morbid conditions and a valuable means of confirmation in doubtful cases; in illustration of which we may refer to the value of a cytological examination of the cerebro spinal fluid in obscure cases of general paralysis of the insane.

---

[4] A lieutenant who, within a reasonable period before the date at which he would otherwise sail for India, furnishes proof of his election to a resident appointment at a recognised civil hospital, may be seconded for a period not exceeding one year from the date on which he takes up such appointment, provided that he joins it within three months of passing his final examination and that he holds himself in readiness to sail for India within 14 days of the termination of the appointment. While seconded he will receive no pay from Indian funds, but his service towards promotion, increase of pay, and pension will reckon from the date borne on his commission. In special cases permission may be granted to lieutenants to delay their departure for India, in order to sit for some further medical examination. Lieutenants remaining in England under such circumstances will receive no pay for any period beyond two months from the date of leaving the Royal Army Medical College, unless the period elapsing before the day on which the majority of the lieutenants of the same seniority sail to India exceeds two months, in which case lieutenants allowed to remain in England will receive pay up to that day. In such cases pay will re-commence on the day of embarkation for India. All the provisions of this clause are subject to the general exigencies of the service. Before the commission of a lieutenant-on-probation is confirmed he must be registered under the Medical Acts in force at the time of his appointment. Candidates who have been specially employed in consequence of a national emergency, either as an officer or in a position usually filled by an [illegible] in circumstances, to reckon such

But important as the advances yielded by hæmatological and cytological methods have been, it is especially the application of that special department of pathology dealing with bacteria and infective organisms in general—viz., general bacteriology—that has within recent years so profoundly altered the status of pathology, for it has yielded not only means of diagnosis almost mathematical in their accuracy in many instances, but also means of treatment so effective and so remarkable as to seem almost miraculous. The exigencies of space forbid us to do more than briefly refer to some of the most notable applications of bacteriology to the problems of disease as they come within the scope of the practitioner of medicine. One of the most striking instances, however, is afforded by the study of the protective mechanisms of the animal body against infective processes and the production of the various bacteriotropic substances, such as the agglutinins, opsonins, bacteriolysins, and bactericidal substances, and in other instances by the formation of antitoxins to counteract the toxins elaborated by the bacteria in their growth. While some of these might at first sight appear to be rather of technical than practical interest, more careful consideration shows that none of them can be ignored in the rational treatment of infective processes. The value of agglutinins as utilised in the Widal method is too widely known to require comment; the application of the opsonic index to the graduation of dosage in treatment by bacterial vaccines, as used by Sir A. E. Wright, is also a matter attracting great attention at the present time; while in the study of immunity and the application of treatment by serums to disease an examination of the character of the serum, as to whether it is bactericidal or antitoxic, demands a knowledge of the mode of action of all the bactericidal substances and antitoxins if it is to be applied rationally. Indeed, the whole subject of the production of antibodies, of hæmolysins, of precipitins is one the practical importance of which it is hard to overestimate. A closely cognate branch of pathological inquiry deals with the effects of animal parasites in the body. Of the brilliant results achieved in this department, both as regards diagnosis and treatment, the English school of pathologists may be justly proud, while the activity at present occurring in regard to the pathology and treatment of trypanosomiasis, sleeping sickness, and other diseases of tropical climates bears witness to the recognition by the public of the importance of this subject. Nor must we forget to mention the application of chemical pathology to diagnosis; while some of the simple processes connected therewith, such, for example, as the investigation of urine, require but little apparatus, and therefore come within the possibilities of the clinical ward or the consulting room, the majority demand complex apparatus and involve methods only practicable within a laboratory. That chemical methods, including quantitative investigation and micro-chemical processes, are destined to play an important part in exact diagnosis in the future few will doubt who consider the so-called nutritional and metabolic diseases, or who realise the important functions of the blood plasma in health and disease, with its internal secretions, its hormones, its waste products, and its nutritive materials.

The fact which stands out from all these considerations is that the application of pathology to medicine, both as regards diagnosis, treatment, and research, requires special men with special training and special laboratories. Bacteriology is a science, and like all sciences demands exact and accurate methods in all its details and all its applications; anything short of these would be worse than useless, indeed, positively dangerous, for in dealing with such materials as vaccines, the dosage is a matter of extreme importance and error or inaccuracy may be attended with serious consequences. Here there is scope for men with special training and with special experience, as we have before suggested, and the progress made in the last few months has served only to confirm the view. A much more difficult question, and one that must eventually come before the authorities responsible for the control of medical education, is the extent to which the student and the practitioner shall be educated in these matters, since the curriculum must sooner or later reach breaking strain. That a knowledge of the general principles of diagnosis and treatment by these methods is necessary is obvious; that the practical study and application of them is not possible for every student is equally obvious, not only from the point of view of the complexity of the methods, but because of the prolonged practice which is necessary for their acquisition and successful application. Moreover, it must not be forgotten that the successful diagnosis and treatment of disease demand a study of the patient at the bedside, as well as the investigation in the laboratory of material emanating from him; and that while work in the laboratory may be of the greatest value it can never replace the study of the actual patient, for when all is said it is the patient who has to be treated, and the choice of the treatment to be adopted cannot be made in the laboratory, but only at the bedside after most careful consideration of all the factors relating to the patient's condition. Thus it would appear that while the laboratory worker may assist in the making of the diagnosis and provide the means of treatment, suggesting and controlling its dosage and the method of its administration, the actual responsibilities of treatment must remain in the hands of the clinician. On the other hand, it should be remembered that in view of the nature of these forms of treatment they should be used scientifically and with due deliberation and not in the haphazard way in which some delight to try the newest synthetic products of the chemical laboratory under the easy delusion that they thus become scientific therapists. No doubt with increasing advances these matters will adjust themselves, but our main thesis at the present moment is that the laboratory worker has established his position in the practice of medicine and that his status is likely to advance in the future.

THE BRITISH MEDICAL MAN ABROAD.

THE conditions of medical practice have much altered in this country of late. Professional incomes in many places have been lowered seriously by the unfair tactics of so-called medical aid societies, and the position of servant to which some of these associations would reduce their medical officer is one that liberally educated gentlemen do not welcome with enthusiasm. We have pointed this out with much detail in many issues of THE LANCET, and we have reason to think that improvement is at hand, but there is yet a time of severe struggle ahead. Again the expenses of living have gone up for medical men as they have for all the middle and upper middle classes of this country, while more money is required to secure the necessary medical degrees and diplomas owing to the lengthy curriculum and the more expensive equipment. These facts account, though only partially, for the increased number of medical men who having obtained British medical qualifications desire to settle abroad. Other factors at work are the spirit of adventure, the feeling that in a new country there is more elbow-room and more chances of getting out of the ruck, and the increased facilities of transport. Newspapers and books galore nowadays make us familiar with life in other lands, while trains and steamers will take us all over the world in a short time and at a comparatively small expense. For this reason or that, the number of medical men who make inquiry from us as to their legal and professional position in a foreign country grows yearly larger, and in the following columns we attempt to give the information.

Speaking generally, our colonies make it easy for medical men from home to practise there, but the same is not the case on the continent, where there is an obvious tendency towards protection. But in the colonies there are not many openings for practice except for those who are willing to "rough" it and work hard. In Canada there are outlying districts where a good start might, perhaps, be obtained; but it must be remembered that Canada possesses advanced medical schools and is a sparsely populated country as yet. In Australia and New Zealand the prospect for the British practitioner is not greater than that which faces him in Great Britain. The medical profession is, in fact, crowded in all places at home and abroad where the circumstances of practice are favourable, and many practitioners who have gone out from the mother country have had to leave the colonies unsuccessful, or have

The prizes formerly open to competition in the old Army Medical School at Netley have been transferred to the Medical Staff College in London and at present they are re-distributed as follows (but the arrangements as regards all the prizes are to be re-made now that all the course is to be attended in London): The Herbert Prize, the Parkes Memorial Bronze Medal, and the de Chaumont prize are now set aside to be competed for by the lieutenants-on-probation of the Royal Army Medical Corps, while the Webb prize and the Pathology prize are competed for by the young officers of both services. The two Montefiore prizes are open to the competition of the lieutenants-on-probation of the Indian Medical Service, and the Martin Memorial Gold Medal is competed for by the lieutenants-on-probation for the same service after the course in Military Medicine. The Maclean prize was withdrawn on the abolition of the Army Medical School and foundation of the Medical Staff College. The Herbert Prize of £20 is awarded to the lieutenant-on-probation who has obtained the highest number of marks at the Staff College examination in London; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in hygiene; the de Chaumont prize of books to the one who takes second place in Hygiene; the Montefiore Medal and £21 are awarded for Military Surgery; the Montefiore Second Prize, a cheque to the lieutenant-on-probation who obtains the second highest number of marks in this branch; a prize of books is given for the highest number of marks gained in Pathology; and the Marshall Webb prize of £5 and a bronze medal is awarded for Hospital Administration.

At the close of the session those lieutenants-on-probation who have obtained one-third of the possible total of marks and have satisfied the authorities that they possess the necessary skill, knowledge, and character for permanent appointment are recommended for commissions as Lieutenants in the Indian Medical Service.[4]

Officers on appointment are, when possible, provided with passage to India by troop transport; when such accommodation is not available passage at the public expense is provided by steamer, or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2*s.* a day. This payment does not include the cost of liquors, which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of terminating his course of instruction, or within 14 days of the termination of his hospital appointment if the Secretary of State has permitted him to hold one will be considered as having forfeited his commission unless special circumstances shall justify a departure from this regulation.

APPENDIX I.

CERTIFICATES OF AGE AND NATIONALITY REQUIRED BY NATIVES OF INDIA.

MEDICAL DEPARTMENT.

The Governor-General in Council is pleased to publish the following rules under which certificates of age and nationality will be issued to natives of India who are candidates for the examinations for the Indian Medical Service held in England.—

General Rules applicable to all Candidates.

A candidate for admission to compete in England for the Indian Medical Service is required before leaving India to obtain a certificate of age and nationality, signed, should he be a resident in British India, by the Secretary to the Government of the Province or the Commissioner of the Division within which his family resides, or, should he reside in a native State, by the highest Political Officer accredited to the State in which his family resides.

Note.—In the case of a candidate who has proceeded to England without obtaining a certificate the certificate may be granted to his father or guardian, provided that the latter produces the requisite evidence, and, when making the application, states when the candidate went to England and where he has been residing during his stay in that country.

In order to obtain a certificate, a candidate is required, if resident in British India, to prove the date and place of his birth before the magistrate of the district in which his family resides, or, if resident in a native State, before the Political Officer of the State in which his family resides.

A candidate must, if resident in British India, signify to the Secretary to the Government of the Province or the Commissioner of the Division in which his family resides his desire to compete not less than three months before the date on which he proposes to go to England. If resident within a Native State, he must signify his desire in like manner to the highest Political Officer accredited to the State within which his family resides.

The officer to whom the application is made shall forward it for the purpose of inquiry to the Magistrate of the district or Political Officer of the State in which the applicant's family resides.

The Magistrate or Political Officer to whom such application has been forwarded shall call upon the candidate to appear and give evidence of the date and place of his birth and of his nationality within one month. He will carefully examine into the value of the evidence given and forward a summary of it, with certified copies of all documents tendered, and his comments and opinion, to the officer who forwarded the application to him for inquiry.

The documentary evidence which a candidate may be expected to produce comprises—(*a*) the horoscope; (*b*) family books; (*c*) tradesmen's account books showing entries relating to the birth; (*d*) the record of admission in the registers of the school in which the candidate was educated and the record of the candidate's age at various periodical school examinations; and (*e*) if the candidate is matriculated a certified copy of his application to the Registrar.

Oral testimony of persons acquainted with the candidate's family or otherwise able to give relevant evidence, will also be taken; and the candidate is required to comply to the best of his power with any requisition the Magistrate or Political Officer, as the case may be, may make in order to clear up any doubt as to the purport of the documentary proof.

Any declaration of age made after the application of these rules on the occasion of seeking admission to any university examination, educational institution, or Government office, or otherwise recorded in a formal and deliberate manner, will be taken as conclusive evidence in disproof of the subsequent assertion by the same person that he is of different age to that so declared or recorded.

Rules to apply to Candidates Born in His Majesty's Dominions.

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, shall be satisfied by the papers submitted that the candidate has stated the date and place of his birth correctly, he will issue a certificate declaring that the candidate has submitted the proofs of his birth to the Magistrate of the district or the Political Officer of the State, as the case may be, and has satisfied him that he was actually born on or about the dates stated by him, viz., the day of , at , a place within His Majesty's Dominions. The nature of the evidence produced by the candidate must be stated in the certificate, which shall be given in the following form:—

> I hereby certify that , who is a candidate for the Indian Medical Service, has submitted the proofs of his birth detailed below, and has satisfactorily shown that he was actually born on or about the date stated, viz., the day of , at , a place within His Majesty's Dominions.
>
> (Here enter details.)

* * * * * * *

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, finds reason to disbelieve that the candidate was born on the day or at the place asserted by him, the certificate will be refused and the candidate will be unable to obtain admission to the competitive examination for the Indian Medical Service.

Where the date and place of the birth have been formally registered in a register kept by any public officer in British India, an extract from the register, duly certified by the proper official, shall be accepted as sufficient proof of the date and place of the birth.

Rules to apply to Candidates not Born within His Majesty's Dominions.

In addition to the particulars required by Rule 2, a candidate not born in His Majesty's Dominions must also prove that he is the son or grandson of a person born in those dominions.

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, shall be satisfied by the papers submitted that the candidate has stated the date and place of his birth correctly, and has established the fact that, though born without the limits of His Majesty's dominions, he is the son or grandson of a person born in those dominions, he will issue a certificate in the following form, stating the nature of the evidence produced regarding the candidate's birth:—

> I hereby certify that , who is a candidate for the Indian Medical Service, has submitted the proofs of his birth detailed below and has satisfactorily shown that he was actually born on or about the date stated, viz., the day of , and that he was born at , a place without His Majesty's Dominions, but that he is the $\frac{\text{son}}{\text{grandson}}$ of a person born in those dominions.
>
> (Here enter details.)

* * * * * * *

If the Secretary to Government, Commissioner of a Division, or the highest Political Officer accredited to the State, as the case may be, finds reason to doubt that the candidate was born on the day asserted besides being liable to the comparatively mild "tassa di famiglia" (tax on domestic servants, &c.), levied on foreign and native residents alike.

---

[4] A lieutenant who, within a reasonable period before the date at which he would otherwise sail for India, furnishes proof of his election to a resident appointment at a recognised civil hospital, may be seconded for a period not exceeding one year from the date on which he takes up such appointment, provided that he joins it within three months of passing his final examination and that he holds himself in readiness to sail for India within 14 days of the termination of the appointment. While seconded he will receive no pay from Indian funds, but his service towards promotion, increase of pay, and pension will reckon from the date borne on his commission. In special cases permission may be granted to lieutenants to delay their departure for India, in order to sit for some further medical examination. Lieutenants remaining in England under such circumstances will receive no pay for any period beyond two months from the date of leaving the Royal Army Medical College, unless the period elapsing before the day on which the majority of the lieutenants of the same seniority sail to India exceeds two months, in which case lieutenants allowed to remain in England will receive pay up to that day. In such cases pay will re-commence on the day of embarkation for India. All the provisions of this clause are subject to the general exigencies of the service. Before the commission of a lieutenant-on-probation is confirmed he must be registered under the Medical Acts in force at the time of his appointment. *Candidates* who have been specially employed in consequence of a national emergency, either as an officer, or in a position usually filled by an officer, will be allowed, under certain circumstances, to reckon such service towards pension.

As to the career Italy offers it is in some respects better, in other respects worse, than it was some years ago. It is better inasmuch as Italian medicine and surgery have greatly improved of late years and the foreign practitioner, particularly in those cities which are the seat of medical schools, is not in danger, as he used to be, of getting out of touch with the advance of the profession. Indeed, the British medical man may keep himself *au courant* with the latest accession to medical doctrine as conveniently in the Italian as in any other kingdom. By graduating at one or other of the many Italian schools he can obtain the *entrée* to the medical societies, the congresses (provincial and national), the hospitals, the class rooms open to the native practitioners, and also become entitled to the reduced railway and steamboat fares conceded on occasion to all duly qualified Italians. Indeed, he is generally welcome to them on the ground of professional *fratellanza* (brotherhood), but the graduation above indicated gives him a right to what he would otherwise owe merely to courtesy. On the other hand, the career is less favourable than formerly on account of the larger number of English-speaking competitors whom it now attracts and who comprise not only Englishmen and Americans, but Swiss, Germans, and other nationalities as well. Their harvest (generally limited to three or four months of the "season") entails immense, almost excessive, activity, compensating the comparative idleness of the months before and after it. Upon this short period of remunerative work the practitioner must therefore rely to carry him through the entire year, and with heavy expenses to meet for housekeeping, house rent, servants' wages, taxes, &c., it becomes a serious matter for him when the "season," as often happens, turns out a poor one. He may certainly be able to supplement his winter's income by taking up practice at one or other of the summer resorts, but such practices are difficult to find and with few exceptions are of little value. Failing this he will find nearly the whole summer on his hands, for it is useless to remain at his post during the hot season while his patients have all left to seek the cooler air of the Alps and the Tyrol or have returned to their own country. Nothing is then left for him but to follow their example and thus to incur the heavy expense of moving somewhere else with his whole family. Nevertheless, for a well-qualified man with sufficient private means to tide him over the first years, and who is possessed of good social introductions, there are always openings where he can still find a profitable *clientèle*, although his possible income at any of the smaller health or pleasure resorts will necessarily be limited.

One word of warning in conclusion. Let anyone who is tempted to buy a practice in Italy proceed with even more caution than he would in negotiating in his own country. In the first place, the foreign population of nearly all Italian towns is largely a floating one, composed chiefly of people who remain for but a few weeks, often for only a few days in one resort and many of whom never come back again. The vendor of a practice in a place of this sort will have many patients on his books whom he cannot possibly introduce in any way to his successor, and a good many others whom he may introduce but who will never return to the locality, or at best do so only at long intervals, and can therefore form no permanent or profitable part of his successor's *clientèle*. His hold upon the practice is, in fact, of a peculiarly personal kind and cannot, in the nature of things, be easily transferred to another. Secondly, the purchaser himself must be a man fitted for this particular class of work, or he may discover too late that he cannot make it pay and that the capital which he has expended has been spent to no purpose. A similar remark is doubtless true with regard to all such transactions, but it applies with special force in the circumstances now under consideration, where the physician has to deal with patients of such varying types and diverse characteristics as are to be met with amongst the travelling public in an Italian health or pleasure resort. To achieve a full measure of success the foreign practitioner in Italy must not only be a man of good all-round attainments, conversant with all branches of his profession, but should be possessed of an unusual share of sympathy and tact, for the exercise of which he will have daily scope amongst patients on whom illness falls with peculiar sadness, alone, as they so often are, and helpless in a foreign land.

GERMANY.

Foreign diplomas are not legally recognised in Germany as entitling their holders to practise medicine, so that British medical men desiring to settle in that country have to attend all the classes and pass all the examinations. A young German before commencing the study of medicine must pass an *Abiturienten-Examen* requiring a knowledge of French, Latin, Greek, mathematics, history, and theology. Or the examination of a *Real-Gymnasium* or an *Oberrealschule* may be passed. In the latter event more stress is laid on modern languages, mathematics, and natural history, and English is required instead of Greek. Foreigners have, as a rule, to pass this examination, but if they have already passed a similar one in their own country they may be exempted from it by a special order to be obtained from the Minister of Public Instruction for each individual case. Medicine can only be studied at a university; the curriculum lasts five years, after the second of which the examination called the *Tentamen Physicum* must be passed; it includes anatomy, physiology, chemistry, physics, and natural history. After the end of the fifth year the student presents himself for the "State Examination," which is practical as well as theoretical, and includes medicine, surgery, obstetrics, gynæcology, pathology, materia medica, and hygiene. After passing the State examination the medical man, previously to obtaining his qualification, has to perform his practical year as clerk and dresser at a university clinic or a recognised hospital. If the medical man wishes to have the title of "doctor" he has to pass another examination, which is little more than a formality, but the degree of doctor without the State examination does not legally confer the right to practise. This title of doctor is granted by every German university to foreigners, but the conditions differ according to the university. Some universities demand a special course of study and others do not, and the intending candidate must in every case make inquiries of the authorities. The law does not allow qualified British practitioners any exceptional facilities in passing the examinations; the time of study may possibly be made a little less than five years for those who have already studied abroad, but a special order, very difficult to obtain, is always required for this purpose. A thorough knowledge of German is essential. The fees for lectures are at least £130 and the examination fees about £12. The fees for the degree of M.D. vary from £10 to £20, being highest at Berlin University, which is the degree that is most popular with alien medical men. There is sometimes no prohibition set against holders of British diplomas practising in Germany, provided they do not make use of any professional titles resembling those of qualified German medical men. Medical men practising in this way must, however, understand that the law regards them as unqualified, and that they have none of the rights or privileges of the medical profession.

AUSTRIA-HUNGARY.

In order that foreigners may legally practise medicine in Austria it is necessary for them to become naturalised Austrian subjects which necessitates five years' residence in the country. In special cases the Minister of the Interior, conjointly with the Minister of Education, may grant exemptions from that rule and may permit foreign holders of diplomas to practise in Austria if they comply with the other requirements. These are: The production of a so-called *Maturitätszeugnis* or certificate of having passed the final examination of the gymnasium, at which the candidate must show a satisfactory knowledge of Latin and Greek, as well as of German or one of the other languages spoken in the Austrian Empire, such as Polish, Bohemian, Italian, also of mathematics, history, natural history, chemistry, and physics. If a British medical man or student has passed a similar examination in his own country he may apply for exemption, which is generally granted; he need only produce proof of his having passed such an examination, in the shape of a certificate, to be translated into German by a properly recognised translator. The medical curriculum lasts 11 semesters, or five and a half years. The holders of foreign diplomas may, however, obtain permission to pass their examinations at shorter intervals than are necessary for the students, so that from 18 months to two years may be reckoned as sufficient. After passing the first theoreticum, or first examination, which comprises biology, anatomy, physiology, and chemistry, and which, as a rule, is passed at the end of the fourth semester, the student is allowed to

Specialist pay at the rate of Rs. 60 a month is granted to officers below the rank of Lieutenant-Colonel who may be appointed to certain posts.

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department. The salaries of these appointments are from Rs. 600 to Rs. 2250 per mensem.

Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment.

Except in the administrative grades and in certain special appointments officers are not debarred from taking private practice as long as it does not interfere with their proper duties.

Posts in Civil Employ.

A large number of posts in civil employ are ordinarily filled up from officers of the Indian Medical Service. Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment. The principal appointments, together with the salaries attached to each, are stated in the following table:—

Description of appointment.	Approximate number of appointments in each class.	Salary per mensem. When held by a Lieutenant-Colonel.	When held by a Major.	When held by a Captain.	When held by a Lieutenant.
		Rs.	Rs.	Rs.	Rs.
Inspectors-General of Civil Hospitals	6	2250-2500	—	—	—
Sanitary Commissioner with Government of India	1	2000-2500	—	—	—
Inspectors-General of Prisons	8	1500-2000	—	—	—
Principals of Medical Colleges	2	1650-1800	1200-1300	—	—
Professorial Appointments	23	1500-1650	1050-1150	800-850	750
Sanitary Commissioners ...	6	1600-1800	—	—	—
Deputy Sanitary Commissioners...	13	1350-1500	900-1000	650-800	600
Bacteriological Appointments	5	1500-1600	1050-1150	700-900	650
Superintendents of Central Lunatic Asylums	6	1400-1550	1050-1150	700-900	650
Superintendents of First Class Central Jails... ...	5	1400-1550	950-1050	700-850	650
Superintendents of Second Class Central Jails	5	1300-1450	850-950	600-750	650
Civil Surgeoncies (First Class)	37	1300-1450	850-950	600-750	550
Civil Surgeoncies (Second Class)	171	1200-1350	750-850	500-650	450
Probationary Chemical Examiner	1	—	—	600-750	550

There are also six Chemical Examiners with Rs. 800-1650 per mensem and a number of Port Health Officers with Rs 750-1950 per mensem. Other appointments of Resident Surgeons and Physicians at hospitals, &c., are on salaries ranging from Rs. 700 to 1650 per mensem. There are also a certain number of appointments under the Political Department on salaries ranging from Rs. 450 to 1450 per mensem, exclusive of local allowances.

23 Qualified officers of the Medical Service are also eligible for appointments in the Assay and Mint Departments. The salaries of these appointments are from Rs. 600-2250 per mensem.

Tenure of Office in Administrative Grades.

The tenure of office of Surgeon-Generals and Colonels is limited to five years.

Colonels, if not disqualified by age, are eligible either for employment for a second tour of duty in the same grade or for employment in the higher grade of Surgeon-General by promotion thereto.

Absence on leave in excess of eight months during a five years' tour of duty involves forfeiture of appointment.

Surgeon-Generals and Colonels, on vacating office at the expiration of the five years' tour of duty, are permitted to draw *in India* an unemployed salary of Rs. 1350 per mensem in the former, and Rs. 1000 in the latter case, for a period of six months from the date of their vacating office, after which they are placed while unemployed on the following scale of pay:—

—	Surgeon-General. Per diem.	Colonel. Per diem.
	£ s. d.	£ s. d.
After 30 years' service on full pay	2 5 0	1 14 0
" 25 " " "	2 5 0	1 10 0
" 20 " " " or on promotion, should this period of service not be completed...	2 0 0	1 8 0

A Surgeon-General or Colonel who has completed his term of service and has reverted to British pay may reside in Europe, at the same time qualifying for higher pension.

Retiring Pensions and Half-pay.

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension on completion of the required periods of service:—

After 30 years' service for pension...	£700 per annum + £350 after three years' active employment in India as a Surgeon-General, or + £250 per annum after five years' active employment as a Colonel or £125 after three years as a Colonel. Eight months' absence on leave is allowed to count towards actual service in those grades.
" 25 " " "	£500 per annum.
" 20 " " "	£400 "
" 17 " " "	£300 "

Service for pension reckons from date of first commission and includes all leave taken under the leave rules.

Time (not exceeding one year) passed on temporary half-pay reckons as service for promotion and pension, in the case of an officer placed on half-pay on account of ill-health contracted in the performance of military duty.

Officers of the Indian Medical Service are liable after retirement on pension before completing 30 years' service to recall to military duty in case of any great emergency arising up to 55 years of age.

All officers of the rank of Lieutenant-Colonel and Major are placed on the retired list at the age of 55, and all Surgeons-General and Colonels at the age of 60, but the Director-General is allowed to serve until he has attained the age of 62 years. If a Lieutenant-Colonel has been especially selected for increased pay and he attains the age of 55 years before he becomes entitled to the pension of 30 years' service he may be retained until the completion of such service, and in any special case, where it would appear to be for the good of the Service that an officer should continue in employment, he may be so continued, subject in each case to the sanction of the Secretary of State for India in Council.

Officers placed on temporary or permanent half-pay are granted half-pay at the following rates.

—	Rates of Half-pay.* Per diem.	Per annum.
	£ s. d.	£ s. d.
Under 5 years' service	0 6 0	109 10 0
After 5 "	0 8 0	146 0 0
" 10 "	0 10 0	182 10 0
" 15 "	0 13 6	246 7 6
Lieutenant-Colonel, under 3 years' service as such	1 0 0	365 0 0
Lieutenant-Colonel, over 3 years' service as such	1 7 6	501 17 6

* Officers cannot retire *in India* on half-pay (No. 45, Feb. 28th, 1865).

An officer of less than three years' service, although he may be transferred to the half-pay list under the general conditions of transfer, will not be granted any half-pay unless his unfitness has been caused by service.

Invalid Pensions

An officer who has become incapacitated for further service in India on account of unfitness caused by duty may, after he has been two years on temporary half-pay, be granted an Invalid Pension on the following scale:—

	Per annum.
After 16 years' pension service	£272
" 15 " " "	252
" 14 " " "	232
" 13 " " "	212
" 12 " " "	192

Wound Pensions.

Officers are entitled to the same allowances on account of wounds received in action and injuries sustained through the performance of military duty as are granted to combatant officers of His Majesty's Indian Military Forces holding the corresponding military rank.

Family Pensions.

The claims to pension of widows and families of officers are treated under the provisions of such Royal Warrant regulating the grant of pensions to the widows and families of British officers as may be in force at the time being.

The widows and families of officers are also entitled to pensions under the Indian Service Family Pension Regulations, for the benefits of which all officers must, as a condition of their appointment, subscribe from the date of their arrival in India, except in the case of natives of India, for whom it is optional.

Honours and Rewards.

Officers of the Indian Medical Service are eligible for the military distinction of the Order of the Bath and for other Orders, British and Indian, and for good service pensions. Six of the most meritorious officers are named Honorary Physicians and six are named Honorary Surgeons to His Majesty. On appointment as Honorary Physician or Surgeon an officer below the rank of Colonel is promoted to that rank, remaining supernumerary until absorbed. A retired officer appointed Honorary Physician or Surgeon to the King is granted the honorary rank of Colonel, if on retirement he had not attained to that rank.

NOTE.—The following is a list of recognised Civil Hospitals.—England and Wales.—London: St. Bartholomew's Hospital, Charing Cross Hospital, Guy's Hospital, King's College Hospital, London Hospital, Middlesex Hospital, St. George's Hospital, St. Mary's Hospital, St. Thomas's Hospital, University College Hospital, and Westminster Hospital. Birmingham: General Hospital and Queen's Hospital. Bristol: Royal Infirmary and General Hospital. Cambridge: Addenbrooke's Hospital. Cardiff: Cardiff Infirmary. Leeds: General Infirmary. Liverpool: Royal Infirmary and Southern Infirmary. Manchester: Royal Infirmary. Newcastle-on-Tyne: Royal Infirmary.

made a name in the scientific world by their writings or unusually successful practice, or who have occupied professorial chairs or other important medical appointments in other countries, may be permitted to practise without any examination, solely on the decision of the Medical Council, confirmed by the Minister of the Interior, as to the worthiness of such practitioners.[1] Previous residence in the country before practice would not be necessary except in the case of the first group mentioned, who would have to pass through the usual five years' course of a Russian medical curriculum. As to the prospects of a British practitioner in Russia the country and the smaller towns can present no attraction to an English medical man, even if the fees obtainable would support him, which they would not. In the two capitals, Moscow and St. Petersburg, the field is wider. Competition is, however, great, fees are as a rule small, and bad debts many. The frequency of bad debts results from the unwritten law by which medical men do not send in accounts, but leave the patient to pay what he considers a suitable amount.

EGYPT.

Duly qualified British practitioners have no examinations to pass and no fees to pay except a nominal sum for registration. They must, however, exhibit their various diplomas to the Director-General of the Sanitary Department in Cairo and obtain a certificate of good character from the British Consul. A knowledge of French or Italian and Arabic would be essential to any newcomer desirous of practising all the year round, for the tourist season only lasts from November to April. Egypt has been a popular place of late with English medical men and there are few or no vacancies for additional English practitioners in Cairo, while the field is already well occupied at Alexandria and the other obvious resorts.

JAPAN.

According to the regulations for medical licence "persons holding either diplomas of foreign universities, or medical schools, or foreign licences for practising medicine may be granted licences for practising medicine in Japan, without being subject to the usual medical examination, upon producing such diplomas or licences obtained in foreign countries to the satisfaction of the home authorities." English medical practitioners will therefore have no difficulty in obtaining a licence in Japan. The fee required for a licence is three yen (about 6s.) and with this exception there are no charges in respect of the medical licence. A local rate, which would be a small fee only, may have to be paid on opening a practice. A correspondent informs us that English practitioners in the foreign quarters of Japan are at some disadvantage for the reasons that the druggists, who are now nearly all Japanese, sell their drugs at a cheaper rate to native practitioners; and, moreover, living is cheaper for the native than for the foreigner. Foreign practitioners depend largely upon shipping and contract business work.

UNITED STATES OF AMERICA.

The laws regulating the practice of medicine in the various States and territories of the United States of America differ to a considerable extent in detail. In spirit, however, they are beginning to assume that uniformity which all medical reformers must desire for them. It has long been pointed out that one of the most open doors to abuse of medical practice in the United States was the fact that while in some States an excellent medical curriculum was required before admission to legal practice, in other States but little scientific training was exacted and freedom to practise was extended to dangerous forms of quackery. This position of affairs had its origin, of course, in the evolution of the United States, certain divisions of the country being in the forefront of civilisation while others were, to say the least, in a rudimentary plight; but of late a great process of levelling-up has been witnessed. The progress of the United States is in no way better shown than in the fact that throughout its vast length and breadth there is now an attempt to secure for the people of the country adequate medical treatment based on scientific grounds. A *résumé* of the legal regulations for medical practice in the States and territories of the United States of America has been published at the office of the *Journal of the American Medical Association*, Dearborn-avenue, Chicago, Illinois. In this digest of the medical laws of the various States, which has been brought quite recently up to date, existing legislation is explained on broad grounds so far as it pertains to medical practice. If the information with regard to some particular State is anywhere scanty in detail it is always possible for the intending practitioner to communicate with the secretary or executive officer of the medical board at the capital of the State.

We must continue to warn the British medical man desiring to practise his profession in the United States of America that in all the more enviable centres he will find a vast number, almost a plethora, of medical men, the great proportion of whom have been thoroughly well educated and trained. He must remember also that in the more important States, generally speaking, although the remuneration may rule high, the expense of living is proportionate. He will understand that the less highly the State is developed the more easy will it be for him to obtain a footing, but the less pleasant in all probability will be his professional career.

CANADA.

The Canada Medical Act, 1902, authorises the creation of "The Medical Council of Canada" with power to establish a qualification in medicine entitling holders thereof to practise in all the provinces of Canada, but no regulations have as yet been issued. As a general rule, the possession of British diplomas and degrees entitles the holders to practise in Canada after having obtained a licence from the provincial medical boards and paid certain fees.

Ontario.—Registration by the Council of the College of Physicians and Surgeons of Ontario is necessary and it is optional for the Council to admit to registration all persons who are duly authorised to practise medicine, surgery, and midwifery in the United Kingdom and Ireland upon terms which the Council may deem expedient.

Quebec.—Practitioners must be licensed and registered by the Provincial Board, which may license without examination holders of medical qualifications from British universities or corporations.

New Brunswick.—Practitioners in New Brunswick must be registered by the Medical Council of the province. A candidate for registration (1) must pass an examination in English, arithmetic, algebra, geometry, Latin, elementary mechanics, elementary chemistry, history, geography, and two of the following languages, Greek, French, and German, unless he has already matriculated at some college in the United Kingdom, Canada, United States of America, or Europe, or holds a first-class teacher's licence from the Board of Education of New Brunswick; (2) he must after- wards have studied for four years and attended some university or college or school of medicine for four sessions of not less than six months each and have attended lectures on anatomy, pharmacy, &c.; (3) he must have attended the general practice of a hospital for 12 months; (4) he must have obtained a degree in the above subjects from a university, college, or school requiring such four years' course of study or must have passed an examination in them before the examiners in New Brunswick; and (5) he must be over 21 years of age. A fee of $10 is required and medical practitioners are liable to an annual fee of from $1 to $2.

Nova Scotia.—Registration and a licence from the Provincial Medical Board are required, which admits to the privileges of practice, upon payment of the registration fee, all persons who are duly registered by the General Medical Council of Great Britain.

Prince Edward Island.—No one can practise medicine, surgery, or midwifery in Prince Edward Island unless regis- tered or licensed by the Council of the Medical Society of Prince Edward Island. The Council admits to the register any person who is duly registered by the General Medical Council of Great Britain.

British Columbia.—No person may practise medicine, surgery, or midwifery in British Columbia unless registered by the College of Physicians and Surgeons of British Columbia. The Council admits to the register any person "who shall produce from any college or school of medicine and surgery, requiring a four years' course of study, a diploma of qualification," on proof of identification and on passing an examination as to his competency. The fee for registration appears to be rather indefinite, as we learn that it "must not exceed $100" and the annual fee is from $2 50 to $10. Licences to practise are issued to women.

Manitoba.—Registration by the Council of the College of Physicians and Surgeons of Manito months shall have elapsed between the attainment of registrable qualification and the time when he presents himself for either part of the examination; (2) he produce evidence of having, after obtaining a registrable qualification, attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration; (3) he produce evidence of having, after obtaining a registrable qualification, attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible to man; and (4) he produce evidence of having, after obtaining a registrable qualification, for six months (of which at least three months shall be distinct and separate from the period of laboratory instruction) been associated day by day in the duty, routine and special, of public health administration under the supervision of: (*a*) in England and Wales either the medical officer of health of a county or of a single sanitary district having a population of not less than 50,000 or a medical officer of health devoting his whole time to public health work; or (*b*) in Scotland or Ireland the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000; or (*c*) a medical officer of health who is a teacher in the department of public health of a recognised medical school; or (*d*) a sanitary staff officer of the Royal Army Medical Corps having charge of an army corps or district; or (*e*) in the British dominions outside the United Kingdom a medical officer of health of a sanitary district having a population of not less than 30,000 who himself holds a registrable diploma in public health. A certificate of an assistant officer of health of a county or a large sanitary district may be accepted, provided the medical officer of health of a county or district consents to the assistant officer giving such instruction. Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation. A candidate who produces evidence that he has himself held, for a period of not less than three years, an appointment as medical officer of health of a sanitary district within the British dominions and having a population of not less than 15,000 shall be exempt from the provisions of paragraph (4). The provisions as to previous study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890.

---

[1] This Section dates from 1838; it was amended in 1842, 1845, and 1867.

The first part of the examination will comprise the following subjects. The elements of chemistry and physics: methods of chemical analysis and in particular the analysis of air and water. The laws of heat and the elements of pneumatics, hydrostatics, and hydraulics in their application to warming, ventilation, water-supply, and drainage. The geological and other conditions determining the healthiness of sites for dwellings. Sources, storage, and purification of water-supply. The elements of meteorology in relation to health. Principles of building construction in their application to dwellings, hospitals, and schools. The disposal of sewage and refuse and the general principles of sanitary engineering. Disinfectants, their chemistry and use. The chemical and microscopical examination of foods and the detection of the commoner forms of contamination. The methods of bacteriological investigation and analysis. The bacteriology of air, water, food, and soil. The general pathology of infection and of the diseases of animals that are transmissible to man. The second part of the examination will have reference to State Medicine and to the applications of Pathology and Sanitary Science, and will comprise the following subjects. Laws and Statutes relating to Public Health.[1] The model by-laws of the Local Government Board. Sanitation of dwellings, schools, factories, and workshops, and of villages and towns. Inspection of slaughter-houses, cowsheds, &c. Inspection of meat and other articles of food. General epidemiology, with special reference to the origin, pathology, symptoms, propagation, geographical distribution, and prevention of the epidemic, endemic, and other infective diseases both of temperate and of tropical climates. The methods applicable to the medical investigation of epidemics. Effects on health of overcrowding, vitiated air, impure water, polluted soils, and bad or insufficient food. Unwholesome trades and occupations and the diseases to which they give rise. Nuisances injurious or dangerous to health. The effects on health of season and climate. The principles and methods of vital statistics in relation to public health. (N.B.—The foregoing schedule is not to be understood as limiting the scope of the examination, which will include every branch of sanitary science. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which bear upon the duties of medical officers of health.) The examinations in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work and one day to oral and practical examination in, and reporting on, subjects connected with outdoor sanitary work. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has passed to the satisfaction of the examiners in both parts. Every candidate will be required to pay a fee of £6 6*s*. before admission or re-admission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be re-admitted to either part on payment of a fee of £5 5*s*. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination and the courses of study in the University should be addressed to Dr. Anningson, Walt-ham-sal, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination must send in their applications on forms supplied for the purpose and transmit them with the fees to Mr. J. W. Clark, Registrary, University of Cambridge, for the April examination on or before March 17th and for the October examination on or before Sept. 15th. The prescribed certificate must be sent to the Registrary so as to reach him not later than 10 A.M. on March 30th and Sept. 28th respectively. Cheques should be crossed "Barclay and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned. The following is a list of colleges and schools of medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the State Medicine Syndicate: The University Laboratories, Cambridge; London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London; University College, London; the Royal Army Medical College, London; the Victoria University of Manchester; the University of Durham Medical School, Newcastle-on-Tyne; University of Birmingham; University of Liverpool; St. Mary's Hospital Medical College; Charing Cross Hospital College; Westminster Hospital Medical School; University College, Bristol; the University of Leeds; Guy's Hospital Medical School; St. Mungo's College, Glasgow; Edinburgh University; Middlesex Hospital Medical School; Royal Southern Hospital, Liverpool; Royal Colleges, Edinburgh; Surgeons' Hall, Edinburgh; Trinity College, Dublin; Queen's College, Belfast; St. Thomas's Hospital Medical School; University College, Cardiff; University College, Sheffield; Medical School, Catholic University, Dublin; St. George's Hospital Medical School; University of Glasgow; University of Aberdeen; Anderson's College, Glasgow; and the Royal Institute of Public Health.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B.Hy.) must be at least twenty-two years of age, registered, and a graduate in Medicine of a recognised university, and at least twelve months shall have elapsed after the date when the candidates obtained their first registrable qualification in Medicine, Surgery, and Midwifery before presenting themselves for examination. They shall spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infectious Diseases, Sanitary

---

[1] All candidates will be examined in the provisions of the English Statutes relating to public health, but any candidate will be given an opportunity of showing a special knowledge of other sanitary laws in operation within the British Empire, provided that, *when applying for admission to the examination, he give notice* of his desire and indicate the special law he proposes to offer.

Except in the case of one patient, who, from repeated explorations with other stethoscopes, was terrified at the proposal to submit to auscultation, it has for some weeks been successfully used in every case of thoracic disease in the Royal Infirmary. It has, however, been objected, that the auscultator could more conveniently suffer his head, with the inflexible instrument, to be raised and depressed by the diseased chest of the afflicted patients, than retain the flexible instrument *in situ*, by means of two fingers at each extremity—often at only one. But this opinion has not been maintained.

It has been objected, that it cannot, *à priori*, be expected, that sounds reflected from angles, could equal in loudness and clearness, sounds conveyed through a straight tube. But reference to the principles alluded to, will have reminded the objector, that the objection is scientifically invalid. The gentleman in question, however, admitted, after accurate and protracted examinations, that the sounds conveyed by the new, were equally loud and clear with those conveyed by the old instrument. It was originally expected, that hard substances should be preferred for the formation of stethoscopes. But every person knows, that some of the phenomena of sound are inexplicable by our present knowledge of acoustics.

It has been urged, that the flexible not being so simple as the inflexible stethoscope, the latter ought to be preferred. Simplicity in the construction of instruments should, doubtless, be always kept in view. But too much is often conceded to abstract terms; and the tube admitting only of so much flexion as convenience requires, it cannot be said that it deviates unnecessarily from simplicity.

These are the principal objections that have been advanced. To all its opposers, however, the writer respectfully replies, that it requires only experiment.

Laennec's, like almost every other invention, has been opposed; but the quick sale of his works proves that his discovery, like that of Jenner, necessarily and rapidly overpowers opposition. The auscultator is, in almost every case, unembarassed by the fallacy of symptoms; and it has been proved that the stethoscope, in many cases, accurately guides, not only with respect to the "repetition, increase, and diminution of remedies," but that it is often indispensable in pneumonia, pleuritis, bronchitis, measles, scarlatina, croup, fever, confluent small pox, extensive erysipelatous inflammation, latent catarrh, phthisis, diseases of the heart, hydro thorax, doubtful cases of pregnancy, &c. It has been shown also, that it affords the surgeon the most important information previous to deciding on the operation for empyema, or for the extraction of foreign bodies from the trachea, in detecting hæmorrhage into the pleura, in ascertaining the state of the lungs previously to the operation for cancer of the breast, caries of the ribs, white swelling, &c; and in the diagnosis of certain fractures, aneurisms, &c.

It is surprising that the discoverer of mediate auscultation did not suggest a flexible instrument. But Laennec, like the gigantic mind of the immortal Archimedes, grappled with great ideas in unexplored regions of thought. He struggled till science hailed him victor. His weapon was genius; his motto, *man*. Contented with the acquisition of all the knowledge attainable by the stethoscope, he despised the drudgery connected with the minutiæ of mechanics, directed his thoughts to great pursuits, and permitted the instrument to be modified by the humblest labourers in the field of science.

It has occurred to me, that both ears might be simultaneously and advantageously employed in stethoscopic examinations. An instrument adapted to this purpose, may consist of a tube, connected at its middle, at right angles to the cylinder, to be applied to the patient, and connected at its moveable extremities with two tubes, moveable also on the principle that has been described. It admits of easy adaptation, both to the ears and the patient.

If this paper should appear not unworthy of insertion, I shall send a drawing of the instrument, with a report of its effects, and the result of an experiment respecting the condensation of the air in the stethoscope during exploration These deviations from the original cylinder, would doubtless have been long since effected, had any person reflected on the obvious modifications of which the inflexible stethoscope admits. Should they facilitate the attainment of so important a study as that of auscultation, it will afford much satisfaction to

Your most obedient servant,
NICHOLAS P. COMINS.

Edinburgh, Aug. 12th, 1829.

"Audi alteram partem."

COMPULSORY NOTIFICATION OF BIRTHS.

To the Editors of THE LANCET.

SIRS,—A distinct understanding was come to more than a fortnight ago between Lord Robert Cecil, Sir Henry Craik, Dr. Cooper, and myself, on the one hand, and the President of the Local Government Board on the other, to the effect that medical men were to be exempted from compulsory notification of births and from all penalties under the Notification of Births Bill. Acting on this assurance, Sir Henry Craik, Dr. Cooper, and I withdrew the motions of which we had given notice. I hold that when Mr. John Burns found that he could not carry his amendment he was bound in honour to withdraw the Bill. Those who pressed for exemption of the medical profession from pains and penalties have, to say the least, been outmanœuvred.

I am, Sirs, yours faithfully,
JOHN BATTY TUKE.

Edinburgh, August 26th, 1907.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

A Health Resort near Rome.

THE first step towards what the Roman public, professional and lay, have long regarded as a desirable consummation—the establishment of a health resort on the site of the so-called "Hannibal's Camp"—has just been taken in the construction of a funicular railway up the Alban Hills to Rocca di Papa. That picturesque village, between two and three thousand feet above sea-level, has for years been utilised as summer quarters for the Roman garrison, but hitherto no attempt has been made to extend a similar advantage to the civil population—viz., to make the fine plateau above Rocca di Papa accessible by rail and available for residents during the great heat. The initial difficulty—that of getting to the place easily within an hour, instead of laboriously on mule or donkey within three times that interval—having at last been surmounted, the next step is the building of a hotel for the accommodation of the holiday-maker or the convalescent. Such an adjunct to the resources of the Eternal City would do much for its attractiveness to the visitor, forced as he has hitherto been to go far afield for summer quarters not nearly so desirable in point of climate and far inferior in the food-supply and the command of professional advice which proximity to the capital can afford. Of these advantages the medical world will have an opportunity of forming an independent opinion a few weeks hence, when the facilities for inspecting Italy's climatic resources which the organisers of the Physio-Therapeutic Congress are furnishing to its members will include a run by rail to Rocca di Papa, to "Hannibal's Camp," and to the Alban Mount—an excursion unique in historic association and picturesque attraction and calculated to convince the most sceptical outsider of the possibility of combining a "winter in Rome" with a not less salubrious and enjoyable summer in its environs.

The Senator Francesco Perona.

Death has been busy in the ranks of the profession, its latest victim being this distinguished surgeon, who died at Novara on August 10th. An ornament of the North Italian School, both as consultant and operator, Perona found time, amid the exigencies of practice, to give the legislature the benefit of his experience, particularly in that primary want of Italy, public hygiene; and during four successive administrations he contributed notably to the improvement of the Codice Igienico in its practical application. On the 12th an imposing funeral attested the esteem in which he was held by the public and the profession; and, after cremation at the cemetery of Novara, his ashes were next day conveyed to Pavia where the customary *oraisons funèbres* were pronounced in commemoration of his life and work.

Medicine of a University of the United Kingdom, or of some other University recognised for the purpose, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. They must also give evidence that, subsequent to graduation in medicine, (1) they have during three months, which must be separate and distinct from the period of laboratory instruction, been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health administration under the supervision of (*a*) a medical officer of health recognised for this purpose by the General Medical Council; (*b*) a sanitary staff officer of the Royal Army Medical Corps, having charge of an army corps, district, or command, recognised for this purpose by the General Medical Council; (2) that they have attended during three months the practice of a hospital for infectious disease, at which opportunities are afforded for the study of methods of administration; and (3) that they have had three months' instruction in mensuration and drawing. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3s. for the First and £3 3s. for the Second B.Sc. Examinations, and £10 10s. for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than 12 months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University, together with having during six months (whereof three months must be distinct from the period of laboratory instruction) been diligently engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health administration under the medical officer of health of a county or large urban district. He must have regularly attended for three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. He must also have obtained practical instruction in the drawing and interpretation of plans. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates must send in their names, with the necessary fee, to the Secretary of the Medical Faculty a fortnight before the examination. The fee is £5 5s. The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period or they may enter for Part I. at one period and for Part II. at another and subsequent period.

Royal University of Ireland.—This University grants a Diploma in Public Health. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of 12 months from the time of obtaining the M.B., B.Ch., B.A.O. degrees; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2, at least one month previously to the examination. Candidates are required to produce a certificate of having, after obtaining the degrees of M.B., B.Ch., B.A.O., attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district. Candidates at this examination must answer in the following subjects: (1) Physics, (2) Chemistry, (3) Meteorology, (4) Sanitary Engineering and Architecture, (5) Bacteriology, and (6) Hygiene, Sanitary Law, and Vital Statistics.

University of Dublin.—The Diploma in Public Health is conferred, after examination, on the following conditions. The candidate must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least 12 months before the examination. The candidate must have completed (unless registered as a practitioner on or before Jan. 1st, 1890), subsequently to registration, six months' practical instruction in a chemical and bacteriological laboratory or laboratories approved by the University, must have studied practically outdoor sanitary work for six months under an approved officer of health (at least three months of this period being distinct from the time spent in laboratory work), and must have spent three months in a fever hospital where opportunities are afforded for the study of methods of administration. The subjects of examination will be:—Part I.: Chemistry, Bacteriology, Hygiene, Pathology (including methods of post-mortem examinations), Physics, and Meteorology. Part II.: Hygiene and Epidemiology, Vital Statistics, Public Health Acts, and Sanitary Engineering and Reports.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health: Section I: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £6 6s. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Victoria Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I. of the examination on producing evidence of being at least 23 years of age, and to Part II. on producing evidence of being at least 24 years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least 12 months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least 23 years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been associated day by day in the duty, routine and special, of Public Health administration during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Par. 2 for Part I.) under the supervision of a medical officer of health who fulfils certain conditions which can be ascertained on application to the secretary[2]; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, after obtaining his registrable qualification in Medicine, Surgery, and Midwifery; and (3) of being at least 24 years of age.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have been qualified for at least one year. Those qualified before

---

[2] Provided that the period of six months may be reduced to a period of three months (which shall be distinct and separate from the period of laboratory instruction required under Regulation 2) in the case of any candidate who produces evidence that after obtaining a registrable qualification, he has during three months attended a course or courses of instruction in sanitary law, sanitary engineering, vital statistics, and other subjects bearing on public health administration given by a teacher or teachers in the department of public health of a recognised medical school.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies may be found.*

TO ADVERTISERS.

Owing to the pressure on our advertisement columns this week some announcements have unavoidably been held over.

Communications, Letters, &c., have been received from—

A.—Dr. W. H. Allchin, Lond.; Mr. R. J. Albery, Lond.; Mr. Algernon Ashton, Lond.; Mr. Sidney Appleton, Lond.; Mr. O. S. Ascherson, Lond.; Dr. James Adam, Lond.

B.—Dr. U. N. Brahmachari, Calcutta; Dr. A. G Banks, Lond.; Miss Bland, Henleaze; Bristol Royal Infirmary, Secretary of; Messrs. Bonthron and Co., Lond.; Mr. T. B. Browne, Lond.

C.—Mr J. H. Chaldecott, Lond.; Dr. W. B. Crowfoot, Beccles; Cardiff Infirmary, Secretary of; Mr. R. A. Caldwell, Broadstone; Messrs. T. Cook and Son, Lond.; Messrs Cassell and Co., Lond.; Canterbury County Borough Asylum, Clerk of.

D.—Mr. G. W. Dawson, Lond.; Dr. J. Dulberg, Manchester; Messrs. Down Bros, Lond.; Devonshire Hospital, Buxton, Secretary of; Divisional Surgeon.

E.—Dr. William Ewart, Lond.; Dr. C. E. Easterbrook, Ayr; Dr. W. McAdam Eccles, Lond.; Major P. Evans, R.A.M.C., Wootton; Messrs. Elliott, Son, and Boyton, Lond.

F.—Dr. Gordon W. FitzGerald, Manchester; Mr. G. Fock, Leipzig; Messrs. Ferris and Co., Bristol; Messrs. R. D. and J. B. Fraser, Ipswich.

G.—Mr. T. H. Griffith, Leamington; Staff Surgeon H. W. Gordon Green, R.N., Devonport; Mr. Thomas Bowden Green, Lond.; Guernsey, Medical Officer of Health of; Miss J. Gould, Chalfont St Giles; Messrs. R. W. Greeff and Co., Lond.; Galen Manufacturing Co., Lond.; Grimsby and District Hospital, Secretary of; Captain H. Garbott, R.N., Lond.

H.—Dr. W. N. Heard, Wareham; Mr. J. Humphreys, Bangor; Mr. M. Hayes, Limerick; Hull Royal Infirmary, Secretary of; Mr. Charles C. Haviland, Frimley Green.

I.—International Plasmon, Lond.; I. H.

J.—Mr. F. Jones, Houghton-le-Spring; J. W. R.

K.—Mr. R. C. B. Kerin, Lond.; Messrs. Knoll and Co., Lond.; Messrs. Knight, Frank, and Rutley, Lond.

L.—Mr. H. Littlewood, Leeds; Local Government Board for Scotland, Edinburgh, Secretary of; London County Council, Education Department, (Executive), Executive Officer of; Messrs. Lee and Nightingale, Liverpool.

M.—Dr. W. Norman May, Lond.; Professor R. M. Meldola, Lond.; Dr. C. R Marshall, Harrogate; Mr. E. Merck, Lond.; Messrs. A. Mather and Son, Lond.; Manchester Medical Agency, Secretary of; Mr. J. Murray, Lond.; M B Lond.; *Midland Counties Herald*, Birmingham.

N.—Mr. J. H. Francis Nunn, Lond.; Nurses' Co-operation, Lond.

O.—D. A. O'Gorman Agency, New York.

P.—Mr. Y. J. Pentland, Edinburgh; Mr. William Partridge, Lond.; Mr. Peter Paterson, Glasgow; *Popular Science Siftings*, Lond., Editor of; Puzzled; Dr. Eldon Pratt, Henfield.

R.—Dr. A. E. Russell, Lond.; Dr. H. D. Rolleston, Lond.; Mr. W. Ramsay, Melbourne; Mr. J. M. Randle, Ruan Minor; Royal Berks Hospital, Reading, Secretary of; Royal Institute of Public Health, Lond., Secretary of; Messrs. Robertson and Scott, Edinburgh.

S.—Professor W. J. Simpson, Lond.; Sheffield University, Registrar of; Dr. J. Scanlan, Glasgow; Messrs. G Street and Co., Lond.; Messrs. H. Simpson and Co., Lond.; Star Engineering Co., Wolverhampton; Southend-on-Sea Corporation, Clerk to the; Smith's Advertising Agency, Lond., Manager of; South Devon, Hospital, Plymouth, Secretary of; Sheffield Union, Clerk to the; Salford Corporation, Clerk to the; Mr. George Safford, Lond.; Dr. G. Arbour Stephens, Swansea; Mr. Sydney Stephenson, Lond.; Dr. H. B. Symons, Matlock; St. George's Hospital Medical School, Lond., Warden of; Mr. J. W. G. Smith, Aysgarth; S. H. F. P.

T.—Dr J. Lewes Timmins, Lond.; Taunton and Somerset Hospital, Secretary of; Dr. J. Taylor, Lond.; Torbay Hospital, Torquay, Secretary of.

V.—Mr. J. W. Vickers, Lond.

W.—Mr. W. A. Wharram, Leeds; Messrs. F. Williams and Co., Lond.; Messrs. W. Wood and Co., New York; West Norfolk Hospital, Kings Lynn, Secretary of; Inspector-General Thomas E H. Williams, R.N., Lo Mrs. Jane B. White, Lo Mr. H. B. Wilkinson, Blackad Mr. R. J. Willan, Newcastle-Tyne.

Y.—Mr. Macleod Yearsley, Lond

Letters, each with enclosure, are also acknowledged from—

A.—Mr. A. Anderson York; Messrs. Armour and Co., Lond.; A. G. S; A. J. A.; Mr. W. Allingham, Delabole.

B.—Dr. H. M. Barker, Harrogate; Mr. B. Barnett, Maisey Hampton; Dr. J. Biernacki, Lond.; Beckett Hospital, Barnsley, Hon. Secretary of; Dr. T W Beazeley, Little Bromwich; Messrs J. H. Booty and Son, Lond.; Messrs. W. H. Bailey and Son, Lond.; Mr. C. Birchall, Liverpool; Sir J. W. Byers, Belfast; Bristol Myers Co, Brooklyn, U.S.A.

C.—Mr. C. E Cowen, Cala; Cameron Hospital, West Hartlepool, Secretary of; Messrs. Curling, Wyman, and Co., Lond.; Crookbury Santorium, Farnham, Medical Superintendent of; Cairo, Department of Public Health, Director-General of; Central London Throat, &c., Hospital, Lond., Secretary of; Carmarthenshire Infirmary, Carmarthen, Secretary of; C. D. R.

D.—Mr. W T. Davies, Llanbister; Mr. J. Dunlop, Lond.; Dr H. Davies, Lond.; Doctor, Pancras road; Dr. Dougal, Pittenweem.

E.—Mr. J. Evans, Maidstone; Mr. H. S. Elworthy, Ebbw Vale; E. H. L.

F.—Dr. L. Faleiro, Beja; Messrs. J. S. Fry and Sons, Bristol; Messrs. Fairchild Bros. and Foster, Lond.; Mr F. T. Fagge, Llanfairfechan; Mr. H. McG. Forbes, Cuminestown.

G.—Mr. R. N. Geach, Charlbury; Mr. C. H. Garland, Lond.; G. D.

H.—Mr R T Harrison, Dordrecht, South Africa; Messrs. Hankinson and Son, Boscombe; H M.; Dr. Humphreys, Port Talbot; Miss M. Hayes Kilwinning.

I.—Dr. R. Ingram, Cincinnati, U.S.A., Invernith Lodge Retreat, Colinsburgh, Secretary of.

J.—Mr. B Jeffrey, Watford; J. S; J. M. K.; J. B.; J. D. M.; J. E H.; Mr. T. Johnston, Rugby; J. H.; Dr. E. Jepson, Durham.

K.—Dr. W. G. King, Lond.; Dr. A. Kershaw, Farnworth.

L.—Dr. R. A. Lambert, Aldbourn Locum, Clay Cross; L. B; Lee General Infirmary, Manager o Messrs. Larcom and Veyse Portsmouth.

M.—Mr. S. W. Milner, Malton Margaret-street Hospital for Co sumption, Lond., Secretary of Male and Female Nurses' Asc ciation, Lond., Superintendent of Dr. T. McCririck, Old Cumnock Mr. A. C. McAllister, Croydon Mr. J. B. McNeild, Peebles M. J. M.

N.—Nurse, Herne Bay.

P.—Mr. J. P. Power, Gosport; Painswick Sanatorium, Gloucester, Medical Superintendent of; Dr. R. H. Pulipaks, Krishnagar, India; Peckham House, Lond.; Medical Superintendent of; Mr. C R Porter, Great Berkhamsted; Paisley Corporation, Town Chamberlain.

R.—Mr. C. A. Ryde, Brussels; Dr. R. R. Ross, Balerno; Royal Victoria Hospital, Dover, Secretary of; Dr. C. Raikes, Lond.; Royal Victoria Hospital, Dublin, Registrar of; R. W. W. S; R. Barry; Miss J. Round, Lond. Mr. W. Powell Rees, Lond.

S.—Mr. D. Sen, Malda, India; Mr. W. Savage, Burslem; Mr. J. Sampson, York; St. Luke's College, Lond., Registrar of; *South Wales Argus*, Newport, Manager of; Surgeon, Kingswear; S. C. C.; S, Brighton; Salford Union, Clerk to the; Messrs Savory and Moore, Lond.; Dr. D. Somerville, Wonersh; Seltzogene Patent Charges Co., St. Helens.

T.—Mr. J. Thin, Edinburgh; Mr. B. N. Howard Tripp, Southwold; Miss Dora Tourle, Ilford.

V.—Mr. C. Veitch, Edinburgh; Mr. J. T. Vulliamy, Rugby.

W.—Mr. H. F. Watson, Glasgow Mr. A. P. Walters, Eigg; W. C.; Mr. F. M. Wildish, Glasgow; Dr. D. E. Walker, Guilsborough; Mr. J. H. Walgate, Beverley; W. M. H.; Messrs. Wilson and Glenny, Hawick.

Y.—Dr. W. A B. Young, South Cave.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies onl hould be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER 31, Rue Bapts, Asnières, Paris.

recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy; (*c*) a course of Lectures on Dental Mechanics; and (*d*) a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns. Candidates may present themselves for the First Professional Examination on production of the required certificates. The Examination consists of Mechanical Dentistry and Dental Metallurgy, the examination in Dental Metallurgy being by written paper. III. The Second Professional Examination.—The candidate must produce the following certificates: 1. Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student. 2. Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology; (*b*) a separate course of Dental Histology, including the preparation of microscopical sections; (*c*) a course of Dental Surgery; (*d*) a separate course of Practical Dental Surgery; (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery; (*f*) a course of Dental Materia Medica; and (*g*) a course of Dental Bacteriology. 3. Of having attended at a recognised dental hospital or in the dental department of a recognised general hospital the practice of Dental Surgery during two years. 4. Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy, (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology, (*d*) a course of lectures on Surgery, and (*e*) a course of lectures on Medicine. 5. Of having performed Dissections at a recognised medical school during not less than 12 months. 6. Of having attended at a recognised hospital the practice of Surgery and Clinical Lectures on Surgery during two winter sessions. 7. Of being 21 years of age. The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers. Candidates may present themselves for the Second Professional Examination after the completion of four years' professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination. The Second Professional Examination consists of: Part I., General Anatomy and Physiology, General Surgery and Pathology; Part II., Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. The written examination in Part I. comprises General Anatomy and Physiology, General Pathology and Surgery, and in Part II., Dental Anatomy and Physiology, and Dental Pathology and Surgery. At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries and may be required to prepare and fill cavities or to do any other operation in Dental Surgery (candidates must provide their own instruments); (*b*) on the Treatment of the various irregularities of Children's Teeth. There is also an Oral Examination. Candidates may take the two parts of the examination together or separately. Candidates must pass Part I. before proceeding to Part II. If they fail in Part I. they are not allowed to proceed with Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in medicine or surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned. The fee for the diploma is 20 guineas and is payable as follows:—Preliminary Science *Examination*, 3 guineas; First Professional Examination, 2 guineas; Second Professional Examination, 5 guineas; the balance to be paid on the completion of the Examinations. The Preliminary Science Examination is held in January, March, or April, July, and October in each year. The First and Second Professional Examinations are held in May and November in each year. Candidates must give 21 clear days' notice of their intention to present themselves for examination.

Royal College of Surgeons, Edinburgh.—For the Licence in Dental Surgery all candidates must pass a Preliminary Examination in General Knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council. A copy of regulations giving a list of Preliminary Examinations recognised for obtaining this Licence, as well as of the subjects of the Professional Examinations, may be obtained from Mr. James Robertson, Clerk to the Royal College of Surgeons, at 54, George-square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd, 1878, are exempt from the Preliminary Examinations. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates who have commenced their studies after Oct. 31st, 1898, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, with Laboratory Instruction, one course of six months; Physics, with Laboratory Instruction, three months; Physiology, with Laboratory Instruction, one course of six months; Surgery, including Surgical Pathology, one course of six months; Medicine, including Medical Pathology, one course of six months; and attendance on the practice of a recognised general hospital, with Clinical Instruction on Surgery and Medicine, twelve months. These courses must have been attended at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology (Human and Comparative) (not less than 24 lectures), with Practical Dental Histology, three months; Dental Surgery and Pathology (not less than 20 lectures), with the Materia Medica and Therapeutics applicable to Dental Surgery, three months; Dental Mechanics (not less than 12 lectures), Theoretical and Practical, with Dental Metallurgy, three months—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised dental hospital and school, as apprentices or otherwise, either before or after registration, for three years. Certificates of attendance on such of these courses as may be respectively required will entitle candidates to appear either for the First Dental Examination or for the First and Second Examinations for the Triple Qualification, as they may select, and subject to the existing regulations for each qualification. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional *Examination*: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Physiology, Chemistry, and Physics. The fee for those candidates who began study after Oct. 1st, 1896, is £5 5*s*. Second Examina*tion*: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10*s*. The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics with Dental Metallurgy. *Candidates* who claim exemption from the First Dental general peritoneal cavity that has not been shut off by adhesions. Now it is just in these the most rapidly fatal forms of peritonitis that we see the least amount of visible peritonitis. I have done a post mortem in a case of this kind and have seen with the naked eye practically nothing that could anatomically be called peritonitis. In such a case there is perhaps a little injection of the peritoneum, but little or no lymph has been poured out and the surface of the peritoneum is quite smooth and shiny. But this is seen only in the most extreme cases where death has occurred within a few hours. And it is seen as a rule only in the case of elderly people in whom the resistance of the peritoneum to bacterial invasion is less than it is in younger subjects. But if the dose of poison is much less and the patient lives for a day or two, then we see a very different state of things. The peritoneum is intensely inflamed, much sticky lymph has been poured out, pus is seen to be smeared all over the peritoneal cavity or to be collected in places into definite abscesses; much thin purulent fluid may be found in the peritoneal cavity. In such a case the peritoneum has made a gallant attempt to shut off or to get rid of the poison. But it has failed; there was too much poison. The patient has died of toxæmia. The peritonitis could not stop the toxic absorption.

And so I come back to the point from which I started when I said that peritonitis is in itself beneficent and protective, acting as it does as a barrier against the further absorption of septic matter. It has happened to myself on many occasions to have had the opportunity of seeing how much septic matter can be dealt with and destroyed by the peritoneum. More than once have I opened the abdomen and seen an abundance of septic matter, lymph, and even pus smeared widely over the peritoneal cavity. A few weeks later the same abdomen was opened for some further operation and little could be seen except a few adhesions. The septic matter had been wholly destroyed and got rid of.

Now let us consider for a few moments the clinical symptoms that may be observed in a case of commencing peritonitis due to the sudden escape of toxic material from a perforated viscus such as the stomach. In the first place there is a more or less severe pain which is usually at first localised to the seat of the perforation, but may be more or less general or may be referred to the region of the umbilicus. The peritoneum is normally insensitive to mechanical injury. This may easily be demonstrated in the course of such an operation as gastrostomy or colotomy when performed, as it sometimes has to be, without an anæsthetic. In such circumstances we all know that the stomach or colon may be pricked or cut without the patient feeling any pain. But the peritoneum is sensitive to such stimuli as the application to it of an irritant poison such as septic material. A sudden severe and persistent pain, accompanied by tenderness and rigidity of muscles over the affected area, is often sufficient for the diagnosis of a perforation of the stomach. It is frequently the duty of a surgeon to operate for perforated gastric ulcer upon such evidence alone. Nausea and vomiting usually follow soon afterwards, but it is not necessary or desirable to wait for the later symptoms such as rapid pulse and elevation of temperature. These latter indicate septic absorption and show that the patient has reached a stage less favourable for operative interference.

Now what does nature do when a sudden invasion of the peritoneal cavity by bacteria takes place? There is immediately a rush of blood to the affected area. The abdominal veins are capable of holding a very large quantity of blood, and a very large quantity of blood is now needed for the great fight which is to take place between the blood plasma and white corpuscles on the one hand and the bacteria on the other. The abdominal viscera then, and especially the great omentum, become engorged with blood. This filling up of the abdominal veins leaves less blood in other parts of the body. Hence in severe cases we have collapse. The arteries are empty and the pulse is feeble. I am aware that other factors, such as reflex inhibition of the heart, may play a part in the production of shock. But I lay special stress on this cause of the shock and feeble, rapid pulse that we may meet with in peritonitis because it ought to teach us that the proper mode of treatment is to replenish the empty vessels by giving the patient fluid, plenty of fluid, to replace that which has gone off to the abdomen. But I shall return to this later.

Concerning the two important symptoms, elevation of pulse and temperature, I need say but little. Everybody knows that of the two the pulse is by far the more important. The temperature may be normal or subnormal in a fatal case of peritonitis. If the pulse is not greatly raised, and especially if its rate be not steadily increasing, there is as a rule no immediate cause for anxiety. Think well of a case of peritonitis in which the pulse-rate remains steadily below 100.

I come next to a symptom which is present in all but the very early stages of peritonitis, and that is *distension* of the abdomen. The intestines become filled with gas. Why this should be so is by no means clear to me. That it is not altogether due to the growth of bacteria is obvious. I presume that it is in some way connected with injury to the nerves of the intestines, although why this should lead to the actual formation of gas I do not know. On a small scale we see this same rapid distension of the intestine with gas when we apply a clamp to the small intestine in the course of an ordinary gastro-enterostomy. Within a few minutes of the application of a single clamp to the loop of jejunum, the latter which was empty and collapsed becomes distended. When the time comes for opening the intestines it is found to be filled with a mixture of mucus and bubbles of gas. A question I have often asked myself without being able to answer satisfactorily is, How far is this distension protective and beneficial? Certainly many cases of slight peritonitis are accompanied by great distension and the patients nevertheless get quite w without operation. On the other hand, it is quite certa that the presence of much distension adds very greatly the difficulties and danger of the case if any large operati be undertaken.

We know but little about the conditions that regulate t absorption of septic matter from the peritoneal cavity. Th great absorption and destruction of septic matter does ta place there is no doubt. What becomes of it? It probably excreted directly into the stomach and perha into the intestines and thus got rid of by vomiting a defæcation. Possibly distension plays an important part this absorptive and excretive process. Certainly free purg tion has an excellent effect in draining away septic produc in many early cases of peritonitis. It is not, howeve always possible or judicious to employ this remedy, becau the movements of the intestines may in certain stages peritonitis do much harm in disturbing adhesions and di seminating poisons over healthy peritoneal surfaces. In lat stages when the intestine becomes paralysed and unable contract, distension is a sign of very bad omen.

There is a class of case in which *great distension* of t whole abdomen occurs early in connexion with the escape a small quantity of septic matter into the peritoneal cavit There is little or no tenderness, the patient's general co dition is good, there is no vomiting, but the pulse is general rapid. In such cases it is generally best not to do any lar operation but to be content with giving plenty of fluid. may illustrate this by a case of acute appendicitis in a you lady whom I saw with Dr. H. Savory at Bedford. There was much distension that I was doubtful whether she had n already got a generalised peritonitis. A small incision a inch long showed that the peritoneum was not everywhe affected. A small gauze drain was inserted, the distensio gradually disappeared, and a few weeks later I removed th appendix with ease and safety, the patient making an ex cellent recovery. Any attempt to remove the appendi during the period of great distension would almost certainl have been attended by grave disaster. In more severe case of the same class there may be vomiting as well and th patient may be so ill that the surgeon is tempted to perfor a large and immediate operation. Two years ago I saw wit the late Dr. William Travers of Kensington a case of wha had been supposed to be one of acute intestinal obstructio The abdomen was greatly distended and very tense an tender and there was much vomiting. After a few hours o waiting the vomiting subsided, then in the course of a fe days the distension subsided completely, and later still removed the appendix by an *easy* and safe operation.

A few words about the effusion into the peritoneal cavit of serous fluid which occurs in so many cases of acute peri tonitis. It is well known that blood serum (or plasma) i bactericidal. The fluid is poured out to help in destroying bacteria. We see this in the cellular tissue when an infected area is surrounded by œdema. According to Sir A. E. Wright, the bactericidal power of serous fluid diminishes in the immediate neighbourhood of an infected area. Its bactericidal power becomes exhausted. Consequently the period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will *be admitted to the degree who has not* attained the age of 21 years on the day of graduation. All candidates are required to have passed the following examinations: the first examination, the second examination, and the final examination. Each examination will include practical work in the subjects offered. All candidates shall be required, before presenting themselves for examination, to furnish to the registrar certificates testifying that they have attended the prescribed courses of instruction in accordance with the regulations of the University in each of the subjects which they offer, and that they have fulfilled the other requirements of the ordinance and regulations in respect of such examination. Candidates for the diploma in Dental Surgery (L.D.S.) are required to present certificates showing that they have attained the age of 21 years, that they have attended courses of instruction approved by the University, extending over not less than four years, and that they have completed a pupilage of three years, two of such years at least having been taken before the First Professional examination. Candidates are required to satisfy the examiners in the several subjects of the following examinations: A preliminary examination in Arts; a preliminary examination in Science; the First Professional examination; and the Final examination. The classes in the Department of Dentistry will begin on Oct. 1st. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology will be given at the University in College-road. The classes in the other subjects and the systematic courses in Dental subjects will be held in the School of Medicine of the University in Thoresby-place. The systematic instruction in the School of Dentistry will be given by the following.—Anatomy: Professor T. W. Griffith. Physiology: Professor de B. Birch. Pathology: Professor A. S. Grünbaum. Medicine: Professor A. G. Barrs. Surgery: Professor H. Littlewood. Dental Surgery: Mr. A. G. G. Plumley. Operative Dental Surgery: Mr. T. S. Carter. Dental Anatomy and Physiology: Mr. A. Alan Forty. Dental Mechanics: Mr. C. Rippon. Dental Metallurgy: Mr. W. Lowson. Dental Materia Medica: Mr. J. H. Gough. The clinical instruction will be given in the Dental Department of the Leeds Public Dispensary, which is recognised by the University and by the Royal College of Surgeons. Applications for the prospectus should be made to the Dean of the Faculty of Medicine.

University of Liverpool (Liverpool Dental Hospital and School of Dental Surgery).—The University grants a diploma in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes' walk from the Dental Hospital. The two institutions are now closely associated and the management of the curriculum is in the hands of the Board of Dental Studies. At the Dental Hospital recent alterations have been made, and as it now stands this school offers advantages to students which are not excelled anywhere. The ground floor of the building contains the following: Extraction room, with all needful appliances; anæsthetic room, specially reserved, with every convenience; and large waiting-room for patients. The first floor has a large board-room and a very comfortable students' room set apart exclusively for the use of students. The whole top floor of the building has been thrown into one fine, airy, and well-ventilated operating room. This room will accommodate upwards of 30 operating chairs, which are of the "Morrison pattern," and each of which has a special electric light suspended before it. In the basement a very convenient workroom has been fitted up containing the necessary requirements, and there are commodious lavatories for students. A new Laboratory for practical mechanical work has also been constructed so as to meet the requirements of the curriculum. It is adequately furnished with all the modern appliances of a dental workshop. A skilled dental mechanic has been engaged and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lecture at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. The staff of the hospital includes 12 honorary Dental Surgeons, a Demonstrator, two Anæsthetists, two House Surgeons, and a Curator. Fees for two years' hospital practice, £21. *Apprenticeship.*—A limited number of apprentices are admitted annually. Fees for three years, £105. Further information may be had from the Warden, Mr. W. H. Gilmour. The various medical and dental lectures *are given at the University of Liverpool. The Anatomical* Department has been removed to a new building, comprising a spacious dissecting room and a museum which contains an excellent collection of skulls illustrative of human and comparative dental anatomy. Fees: The composition fees are as follows: Diploma course (L.D.S.): Chemistry and Physics, £11 11*s.*; all other lectures, £50 in two instalments. Degree course (B.D.S.): £67 10*s.* for all lectures (including Chemistry, Physics, and Zoology) in three instalments. Two years' dental hospital, £21; general hospital practice, £10 10*s.*; three years' mechanical instruction (pupilage), £105.

University of Manchester.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the *requirements* of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given during the Winter and Summer sessions both at the University and at the Victoria Dental Hospital in Devonshire-street. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department and for them a separate laboratory for Practical Anatomy and common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, payable in two equal instalments at the *beginning* of the first and third years of studentship. The composition fee for candidates for the University Diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. The composition fee for candidates for the L.D.S. of England is 60 guineas, payable in two equal instalments at the beginning of the first and third years of studentship. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The payment of any of the above composition fees will entitle the student to attend all the classes in the following list which are required for their respective examinations. The composition fee does not include the hospital fees, the examination fees, the fee for the conferment of the degree or the diploma, the registration fee, nor the fees for chemicals and chemical apparatus (£1 15*s.*).

TEACHING INSTITUTIONS IN DENTISTRY.

See also under Universities of Birmingham, Leeds, Liverpool, and Manchester above.

LONDON.

Royal Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the mechanical training recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. One Entrance Scholarship of the value of £20. The Saunders Scholarship awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. Prizes methods, I think that as a rule the less that is done to the peritoneum by washing or sponging the better, and that free drainage usually affords the best means of getting rid of the extravasated septic material. But it is impossible to treat all cases according *to any fixed rule*. In this second class of cases it is best, in my opinion, to avoid purgatives at all stages, to give at first nothing at all by the mouth, but to give fluid, if necessary, by the *rectum* or *subcutaneously*. In many of the less severe cases the administration of water by the mouth does no harm.

III. *The next class is a very important one* and includes the great majority of the cases of appendicitis that we see in practice—at any rate, in surgical practice. These cases are usually seen at some later stage than those of the two classes I have already mentioned. This class includes those in which there is considerable peritonitis involving much of the *peritoneal cavity*, with *more or less tendency* to the concentration of the inflammation in one region. The septic fluid, sero-pus or pus, is more or less localised. Most of the *cases of acute appendicitis* with *abscess* belong to this class and many of those without abscess. There is usually a good deal of distension of the abdomen with rigidity and tenderness, but the latter is more marked in one part of the abdomen than elsewhere. Nausea and vomiting are present if food is taken. The pulse and temperature are probably both above the *normal*. Whether *the patient looks very ill* or not depends not so much on the amount or nature of the septic material within his abdomen as upon the amount *of septic absorption that is taking place from the septic* focus. A patient may have a horribly septic focus in his abdomen, a perforated or gangrenous appendix surrounded by very offensive pus, and yet *he may be suffering* very little from absorption if the septic focus is well shut off by omentum and adhesions and is not under conditions of great tension. I desire to draw your attention especially to this point because one sometimes hears a surgeon speak as if the mere existence of such a septic focus were *in itself a sufficient reason for its immediate removal* by operation. The operation for its removal may be far more dangerous than leaving the septic focus where it is; at any rate, *for a short time until a more favourable period for* operation has arrived. Ochsner's opinion and statistics strongly support this conclusion.

Now how are we *to treat these cases? Our* natural surgical tendency in such cases is to remove the septic focus as soon as possible, and a great many surgeons, I think the majority of the surgeons who write upon appendicitis, teach that this should be done. In some cases it is undoubtedly good treatment to do so. But in many cases I venture to think that immediate operation is very bad treatment and does immense harm. When we are brought face to face with one of these cases we ought, I think, to ask ourselves first of all what is likely to be the course of events if we do not operate at once? Secondly, what good and what harm may we do by operating at once? Thirdly, if we do operate what manner of operation should we do, for there are several?

The ordinary course of events in the majority of cases in my experience is that the symptoms increase in severity up to a certain point and then recede as the septic matter becomes more localised or as it is completely absorbed. When localisation has taken place *then an operation should* be undertaken for the evacuation of the pus, or in cases where there is no abscess, for the removal of the appendix or other primary source of infection. In a *minority of cases*, in my experience a small minority, *provided that the case be properly treated* throughout, the inflammation will continue to spread and the patient will either die or will pass into the next class of case which I propose to discuss.

It is exceedingly hard in a given case to give an accurate *prognosis*. *The duration of the illness*, the stage which it has reached, the severity of symptoms, and especially the increasing severity of symptoms are the points upon which which we must endeavour to base our prognosis and consequently our treatment. But the great majority will improve and pass into a more favourable *condition* for subsequent operation if not interfered with by operation at this acute stage. If it is decided to abstain from operation at this stage it is extremely important that other treatment should be carried out rigidly. The most important point is *not to give purgatives* or large enemata and *not to give food by the mouth*. The patient can do very well without any food for a day or two, and if it be necessary to give him nourishment this can be administered quite well by means of *small nutrient* enemata. *If the* patient is thirsty he should be given fluid and the most convenient way of doing this is to inject co siderable quantities *very slowly* by the rectum. Care shoul be taken not to distend the rectum, but to let the fluid ru in so slowly that it is absorbed as fast, or nearly as fast, as enters. If the patient is not thirsty there is no need to giv much water. He *should be kept as* quiet as possib and should be placed in such a position that the thorax considerably higher than the pelvis. Any fluid within th abdomen will then tend *to gravitate towards* the iliac fos or the pelvis, situations in which it can subsequently be mo easily dealt with.

For some years I have *treated cases of acute* appendiciti of this class and the next on these lines. The number o cases I have had to deal with is no doubt smaller than th number that come to surgeons who have written much o appendicitis. I suppose, too, that I must have bee singularly favoured by good fortune, for in the last tw years I have lost but a *single case of acute appendiciti* either in hospital or private practice—a boy who came int hospital on the second day of a very acute attack. He wa not operated upon and he died two days later. A necrops showed a considerable abscess which had burst, evidentl before admission to hospital, and which had set up a gener peritonitis. A stout old lady of over 60 years of age whom saw with Dr. Charles Drage of Hatfield also died from per tonitis without operation. She was very fat and in bad con dition and her peritonitis may possibly have been due t appendicitis, although I think it was due to another caus *There was no post-mortem* examination. The boy migh perhaps have benefited had he been operated upon when first saw him, although even then his chance of recover would have been poor. *The old lady was one upon whom n* prudent surgeon with any regard for his patient could hav operated with the least chance of success. On the othe hand, I can point to a considerable number of cases of acut appendicitis with peritonitis which I have had to trea within the same period, upon none of which did I do an *immediate operation and all of them have recovered*. Som underwent no operation at all; most had the appendi subsequently removed in a quiet interval; *others ha abscesses opened at a later stage at periods varying* from day or two to several days after I first saw them.

But I have no desire to dwell upon my own cases. *prefer to bring forward* the very large and detailed series of cases published by Dr. Ochsner,[3] who, like so many American surgeons, has had an unusually large experience of appendicitis. He deals with 1000 cases of appendicitis and his results are tabulated as follows: Chronic appendicitis or interval operations, 540; mortality, ·5 per cent. Acute appendicitis without perforation, 255 cases; mortality, 1·9 per cent. (of these six entered the hospital within 36 *hours of the attack*). *Acute appendicitis*, perforated or gangrenous, without abscess, 55 cases; no deaths (of these five entered the hospital within 48 hours of the attack). *Acute appendicitis*, *perforated*, with abscess, 117 cases; mortality, 3·4 per cent. Acute appendicitis with diffuse peritonitis, 33 cases; mortality, 30 per cent. Of the total number of 1000 cases 22 died. "Of the 255 acute appendicitis cases without perforation, 200 were operated upon immediately on entering the hospital and 55 were treated by gastric lavage and absolute prohibition of food and cathartics of any kind by the mouth, the nutrition being accomplished by *means* of small enemata. Of the 55 cases, perforated or gangrenous, but without abscess, 21 were operated on at once and 34 were first *starved* until they seemed in a safe condition for operation. In most of these cases the appendix was completely surrounded by the omentum and held away from all other abdominal structures. Of the 117 cases of acute appendicitis in which abscess had formed, 39 were operated on at once and 78 were treated by prohibition of all *nourishment and cathartics* by the mouth until their condition seemed sufficiently improved to make the operation appear safe. Of the 33 cases entering with diffuse peritonitis *resulting* from perforated or gangrenous appendicitis, all were treated at first with gastric lavage and exclusive rectal feeding. Of *this* class a number were in a dying *condition* when they arrived at the hospital, which accounts for the high mortality in this class of cases. Seven of these cases were not operated *on* for the reason

[3] A Review of the Histories of One Thousand Consecutive *Cases of* Appendicitis operated on at the Augustine Hospital during the thirty-three months from July 1st, 1901, to April 1st, 1904, *by A. J. Ochsner*. A full abstract of *this paper* will be found in the *Journal of American* Medical Association, Dec. 17th, 1904, from which I quote.

Faculty, Professor Edward Fawcett, University College, Bristol.

Devon and Exeter Dental Hospital, 24, Southernhay, West, Exeter.—Established 1880.—The hospital is open daily (Sundays excepted) and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M Ackland; hon. secretary, Mr. Henry Yeo.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in a spacious and well-equipped building at 31, Chambers-street and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. For the special classes, both theoretical and practical, required by dental students the directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £31 10*s*. The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £90 7*s*. Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow is recommended. The minimum cost of the Professional Education Triple Qualification and Licence in Dental Surgery amounts to £169 7*s*. The mechanical department is large and airy and furnished with all modern tools and appliances. The winter session commences Oct. 1st. The Museum is open to students for study. Further particulars can be obtained from the Dean, Mr. W. Guy.

Incorporated Glasgow Dental Hospital and School, 15, Dalhousie-street, Garnethill, Glasgow.—The winter session will begin in October and the lectures will be delivered as follows. In Dental Mechanics on Monday and Wednesday at 7 P.M., by Mr. Hugh McKay, and in Dental Metallurgy on Tuesday and Thursday at 7, by Mr. W. Bruce Hepburn, L.D.S. Fee for each of the above courses of lectures, £3 3*s*. The lectures and instruction at the Glasgow Dental Hospital and School are recognised by all the licensing bodies in the United Kingdom. The fees for two years' hospital practice are £15 15*s*. Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental students. The hospital is opened daily from 5 to 7 P.M. (Saturdays excepted). Students may only enrol during the months of April or October. Summer session begins in April.

Glasgow Royal Infirmary (Dental Department).—Mr. Wm. Taylor attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of instruction in Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital. The winter session opens Thursday, Oct. 17th.

ANCILLARY SCIENTIFIC INSTITUTIONS.

ROYAL COLLEGE OF SCIENCE, London (with which is incorporated the ROYAL SCHOOL OF MINES).—Mechanics and Mathematics: Professor J. Perry, F.R.S., and Dr. A. R. Willis. Biology: Vacant (Zoology), and Professor J. B. Farmer, M.A., F.R.S. (Botany). Chemistry: Professor W. A. Tilden, F.R.S., and Dr. M. O. Forster, F.R.S. Physics: Professor H. L. Callendar, F.R.S., Dr. W. Watson, F.R.S., and Mr. A. Fowler. Geology: Professor W. W. Watts, F.R.S., and Dr. Cullis. Metallurgy: Professor W. Gowland. Mining: Professor S. H. Cox (temporary). The College reopens on Wednesday, Oct. 2nd, 1907. Communications should be addressed to the Registrar, Royal College of Science, South Kensington, S.W.

ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, Faraday House, 62–70, Southampton-row, W.C. —Principal, Hugh Erat Harrison, B.Sc. Lond. Instructor in Mathematics: Alexander Russell, M.A. Glasgow and Cambridge. Instructor in Chemistry: Mr. J. Thomas, B.Sc. Lond. Instructor in Mechanical Engineering: Mr. Walter H. Bell, A.M.Inst.C.E. This institution, in addition to its ordinary course of training in electrical engineering, which occupies four years, also arranges for special instruction in all branches of electricity either by private tuition or by a specially arranged course at the College or at the works of the companies with which it is associated. There are Entrance Scholarships of the value of 150 and 100 guineas. Particulars may be obtained on application to the Secretary, Mr. Howard Foulds, Faraday House, Southampton-row, W.C. Session begins Sept. 23rd.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: Professor Arthur W. Crossley (Dean of the school). Botany: (Vacant). Pharmaceutics: Professor Greenish. The session commences on Monday, Sept. 30th. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges. Application for admission to the school, or for further information, may be made to the Registrar, 17, Bloomsbury-square, London, W.C.

ROYAL SANITARY INSTITUTE (WITH WHICH IS INCORPORATED THE PARKES MUSEUM), PARKES MUSEUM, MARGARET-STREET, REGENT-STREET, W.—The objects of the Royal Sanitary Institute are to promote the advancement of sanitary science in all or any of its branches and to diffuse knowledge relating thereto. It was founded in 1876 and incorporated in 1888. Sessional meetings are held in London and in various provincial centres from time to time for the reading of papers and for discussions upon subjects connected with sanitary science, and lectures and demonstrations are arranged for sanitary officers in sanitary science as applied to buildings and public works. The lectures and demonstrations are suitable for foremen of works, builders, and those engaged in the allied trades; for army officers and professional men on food and meat inspection; for meat inspectors; and for school teachers. Examinations are held in London, provincial, and colonial centres and certificates of competency in sanitary knowledge are granted. The Parkes Museum, which is maintained by the institute, contains a great variety of the most approved forms of apparatus and appliances relating to health and domestic comfort. Professors and teaching of hygiene are allowed the use of the museum for demonstrations to their students on application to the committee. The museum is open daily from 9.30 A.M. to 5 30 P.M. and on Mondays to 8 P.M. and is free of charge except when lectures or meetings are being held. There are also a large library of sanitary literature which contains, in addition to standard works on sanitary science, a collection of reports of medical officers of health over the whole country, and a reading room supplied with the principal sanitary periodicals, both home and foreign. The institute is under the patronage of the King and the officers are: President, the Duke of Northumberland; chairman of council, H. D. Searles Wood, F.R.I.B.A.; treasurer, Mr. Thomas W. Cutler, F.R.I.B.A.; *registrar*, Mr. A. Wynter Blyth, M.R O.S.; and secretary, Mr. E. White Wallis. The lecturers are Dr. J. Priestley, Dr. G.

and Mr. Morison has recently told me that with regard to this particular class of cases he has largely given up his former practice of operating upon them.

A few words about the posture which a patient with suppurative peritonitis should be made to assume. For a long time, as I have already said, I have been in the habit of raising the shoulders of my patients so that fluid in the peritoneal cavity may gravitate towards the pelvis where it can be most easily and safely dealt with. Murphy carries this practice much further and according to Gibbon and Fowler he "has been so much impressed with the advantage of the sitting posture that he now has cases of peritonitis brought to the hospital in the ambulance, *anæsthetised*, placed on the table, and operated upon in this position." I feel sure that Murphy is entirely right and I wish that I could persuade all those who send cases of peritonitis to the Royal Free Hospital to adopt the same precautions.

And now, in conclusion, let me add a few words about that most fruitful source of peritonitis, I mean, of course, acute appendicitis. It may seem to you an extraordinary thing for me to say, but I say it with deliberation and with a profound conviction of its truth, that the very high gross mortality in acute appendicitis which undoubtedly exists in this country (and in other countries as well) is largely due to the fashion of indiscriminate, excessive, and injudicious operating which not long ago was at its height but which, I venture to think and hope, is now showing signs of subsiding. Appendicitis may or may not be more common than it used to be. Personally I do not think it is, although no one can deny that it is more often diagnosed and I have no doubt that deaths from it are much more common than they used to be. It is not unusual to hear it stated that modern operations for appendicitis have resulted in a great saving of life. I believe that, on the whole, the exact converse is the case. If we were all to go back to the old treatment of appendicitis that was in vogue 25 years ago, and that is still in vogue in many parts of the country, there would be a lesser mortality from appendicitis than is the case at present. This is a very different thing from condemning all operations for acute appendicitis, which I am far from doing. Nor do I wish to detract from the excellent work that is done by many surgeons of large experience who advocate, and perform, frequent operations for appendicitis and publish very often brilliant results. I am thinking rather of the far larger number of operations performed by those who do not publish their results, performed by those who do not discriminate sufficiently between the cases that should be operated upon and those that should not be operated upon. It is the doctrine of "Here is a septic focus, let us take it out now at all costs," that, in my opinion, does so much harm. It is for more discrimination in the choice of an operation, in the kind of operation, in the stage at which it should be performed, that I would venture to plead.

ACUTE YELLOW ATROPHY OF THE LIVER FOLLOWING OPERATION FOR INTESTINAL OBSTRUCTION.

By C. E. CAMPBELL-HORSFALL, M.B., CH.B. VICT.

ALTHOUGH from time to time cases of acute yellow atrophy are placed on record, yet it remains one of the rarest diseases met with and its causation as inexplicable as ever. But cases following operations are rarer still and with but one exception have all ended fatally. Perhaps before discussing the case which is the subject of this paper it would be well briefly to review the general features of acute yellow atrophy. Osler defines it as jaundice associated with marked cerebral symptoms and characterised anatomically by extensive necrosis of the liver cells with reduction in volume of the organ.

Etiology.—This is one of the rarest diseases. There are not more than 300 cases on record. It generally occurs between the ages of 20 and 30 years, but cases have occurred in quite young children and even in infants. It is more common in women than in men and seems to have a remarkable connexion with pregnancy. It has followed fright or profound mental emotion and is sometimes secondary to other ailments—typhoid fever, sepsis, syphilis, gonorrhœa, and phosphorus, antimony, and arsenic poisoning. Although the symptoms produced by phosphorus poisoning are very similar to those of acute yellow atrophy the two conditions are not identical.

Morbid anatomy.—The liver is greatly reduced in size, looks thin and flattened, and sometimes does not reach more than one-half or even one-third of its normal weight. It is flabby and its capsule is wrinkled. On section the colouring is mottled, there being red and yellow areas of softened liver tissue. The organ may cut with considerable firmness. Microscopically the liver cells are seen in all stages of necrosis and in spots appear to have undergone complete destruction. The bile ducts and gall-bladder are empty. Hunter considers that it is a toxæmic catarrh of the finer bile ducts, similar to that which is produced after poisoning by toluylene diamin or phosphorus.

Symptoms.—Commences usually as a gastro-duodenal catarrh and at first the jaundice is thought to be of simple nature. This generally lasts a few days and then severe symptoms set in, headache, delirium, trembling of the muscles, and in some instances convulsions. Vomiting is a constant symptom and blood may be brought up. Hæmorrhages occur into the skin or from the mucous surfaces. Pregnant women may abort. With development of head symptoms jaundice usually increases, coma sets in, and gradually deepens until death. The temperature is variable, sometimes afebrile and in some cases marked pyrexia occurs. Usually the temperature rises just before death to 105° or 107° F. The pulse is usually rapid and the tongue is coated and dry. The individual enters into a typhoid state. The urine is bile-stained and contains tube casts. Leucin and tyrosin crystals are not constantly present. The stools are clay coloured from the absence of bile. Cases are almost invariably fatal, there being but few instances of recovery. Nineteen recoveries have been collected by Weising and Ballin. No known remedies have any effect on the course of the disease.

As a sequel to operations Max Ballin has collected ten cases from the literature, a table of which I append below, including the one that came under my own observation. All of these cases, with the exception of Ballin's own case, died.

The following are the notes of the case under my care. On the evening of May 31st, 1904, I was called to see the patient, a young married woman. She complained of severe pain in the lower part of her body and had vomited several times. She had not been feeling well for some time, and two days before I saw her she had had a slight shivering fit. When I saw her she looked anxious and was in evident distress. She had a pulse of 100 and her temperature was 100·5° F. On further examination I found great tenderness over the abdomen in the lower part, most marked in the left iliac region. No tumour could be felt and there was no marked dulness. The abdomen moved readily with respiration. I elicited the following further facts. She had been perfectly regular until her last period, which occurred a fortnight previously to the present attack, when she only lost a small quantity of blood, and this not until six weeks after her previous period. She had been very much troubled with constipation which had latterly become much worse. She also suffered from intense dysmenorrhœa, being utterly prostrated during the menstrual flow. A vaginal examination revealed marked fixation of the uterus, but otherwise it was negative. The rectum was empty. The patient was kept in bed and a small dose of calomel was administered. On the next morning there had been a slight watery action of the bowels. The temperature was 99°, the pulse was 100, the pain was more severe, and the vomiting continued, there being nothing distinctive about the vomit. I saw the patient later in the day, when her condition had not improved. A definite mass could be now felt below and to the left of the umbilicus. Vomiting continued, though not fæcal, and the bowels refused to act. There was no marked distension of the abdomen and no visible peristalsis was present. The pulse was still rapid but the temperature was normal. As the symptoms pointed to intestinal obstruction I decided to operate.

The patient was removed to a nursing home, and on the afternoon of the same day chloroform was administered and the abdomen was opened in the middle line below the umbilicus. On opening the peritoneal cavity a little serous fluid escaped. There were marked signs of an old peritonitis, the pelvic viscera being matted together. The cæcum had been dragged over and was fixed on the left side of the abdomen together with the appendix, which was firmly adherent to the cæcum in its entire continuity. The appendix

Annotations.

"Ne quid nimis."

THE PRACTICE OF MEDICINE IN EGYPT.

ANY person in possession of a diploma from a recognised school of medicine is allowed to practise his profession in Egypt after having *presented his diploma* at the Public Health Department for verification and paid a small fee of six piastres. From a recent report of the department it appears that the influx of medical men into Egypt of late years has been very great, so that it is difficult to understand how some are able to gain a livelihood from their profession. The effective control of diplomas which emanate from so many different foreign schools must be at times somewhat difficult, as the Public Health Department has no means of identifying the person who presents the diploma as the person who underwent the examinations which entitled him to it—*e.g.*, there is nothing to prevent a person who has come into possession of a diploma by fraudulent means personifying the legitimate owner of the diploma and *obtaining a licence to practise*. It is true that in addition to the diploma a certificate of good conduct is necessary from the applicant's Consul before a licence to practise is granted, but in many cases the Consul finds himself in the same difficulty as the department with regard to ascertaining if the person in possession of the diploma is the rightful owner or not. We recommend any one of our readers who is attracted by the idea of medical practice in Egypt to obtain introductions to a resident in Egypt so that he may ascertain the chances of finding a remunerative opening and be provided with a witness to his identity.

SURGICAL TEACHING AT BUDAPEST.

OUR Special Correspondent in Budapest recently stated in one of his communications that Budapest is being resorted to by foreigners for the study of surgery more and more every year. In these circumstances it is well to repeat a word of warning which he gives to intending students. If those who go to study surgery at Budapest would first take the trouble to find out the conditions which obtain at that centre much vexation could be avoided. When it is remembered that surgeons like Professor Dollinger, Professor Réczey, Professor Herczel, and Professor Navratil have as many as 10 or 12 assistants each, and that all these gentlemen stand round the operating table as a right, and because it is their business so to do, it will be easily understood that other spectators in the theatre may reap but little benefit from their view of what is going on. The reason for this great number of assistants is that in Budapest it is not considered unethical to state the fact of association with one of the great clinicians in a somewhat prominent way on the professional card and door-plate. As a matter of fact, the most advantageous way of studying surgery at Budapest is to take out, under one of the chief surgical assistants, a course of operations on the cadaver. This work is carried out with the personal assistance of the teacher, and in this manner a competent knowledge can be obtained. With regard to gynæcological operations, the best way to secure any return for the trouble and expense of studying at Budapest is to pay for a course of instruction under one of the chief assistants of the gynæcological surgeons, and this secures a welcome in the operating theatre. The amount of material in the hospitals of Budapest attracts a large number of students; but it is well for foreigners to remember that much time can be saved by careful selection of the methods of study.

THE Notification of Births Bill passed its third reading in the House of Commons on Friday, August 23rd. The Bill, which deals with a subject of great importance, was debated at length.

Surgeon-General Sir Alfred Keogh, K.C.B., Director-General, Army Medical Service, has been appointed an honorary physician to the King, *vice* Surgeon-General A. F. Preston.

THE DEVELOPMENTS OF PATHOLOGY IN RELATION TO THE PRACTICE OF MEDICINE.

WHILE pathology as one of the branches of biological knowledge ancillary to medicine is of comparatively recent development the progress it has made and is still making renders it a study of the utmost practical value. In our Student's Number of last year we pointed out the important assistance afforded to the practitioner of medicine in his daily routine by the institution of laboratories for clinical and pathological research, and insisted on the importance of special scientific training for those in charge of them. It is an interesting and instructive exercise to endeavour to review in this connexion the influence of pathology on the science and art of medicine. At first pathology seems to have been largely speculative, and to have afforded modifications of the fantastic conceptions of the mediæval schools of medicine in the light of dawning physiological knowledge, and as it evolved to have substituted working hypotheses upon the increasing array of facts observed. In this stage pathology was, as it was once epigrammatically defined, "physiology in difficulties." The increasing attention paid to morbid anatomy during the nineteenth century, notably in its latter half and especially under the stimulus of Virchow's illuminating researches and his epoch-making treatise on "Cellular Pathology," established the study of disease upon a truly objective basis, and the dead-house was for the time the home of pathology. By this means a vast amount of knowledge accrued—a knowledge of the topography of disease *processes, of their effects*, and of their terminations. Valuable as it was, and essential as it still is, *to the education of the scientific* practitioner of medicine, this information, while it rendered services to diagnosis which it is hard to over-estimate, yielded little, if any, advance in treatment; indeed in many philosophical minds it engendered a scepticism and a hopelessness as to the value of treatment which were a hindrance to progress in this respect. Moreover, it is now clear that the study of morbid anatomy, although it supplies information as to the results and the terminations of disease, yields little or none as to the processes underlying or causing the diseased condition of the organism.

The application of the microscope to the study of pathology opened the door to a much more true conception of morbid processes and helped to render pathology a vigorous and practical science. At first it served to vivify the dry bones and dead tissues of morbid anatomy and to bring the pathologist in closer touch with the actual processes of disease. A further advance was *marked* by the application of organic chemistry to the study of pathology, whereby the *department of chemical* pathology was founded, a branch of the science which has yielded great results although even yet in its infancy. At the same time the increasing application of the experimental method in physiology and its application to pathology served at last to bring the actual mechanism of disease within the scope of the investigator, and pathology found its present level. Thus far, however, it had practically been only of theoretical and academic interest and, apart from the examination of urine and other excreta and the microscopical examination of tumours, it played but little practical part in the routine of practice. With the increasing use of the microscope and its application to the study of the blood, elaborated by the researches of Ehrlich, Weigert, Kanthack, Hardy, and others, matters became altered and pathology became now of general diagnostic usefulness, at first in regard to the so-called blood diseases, and later as a valuable adjunct in the recognition of many infections; so that at the present time the scientific examination of the blood is a valuable aid to diagnosis and a three cases the anæsthetic used has been chloroform or some preparation of chloroform, so naturally the question arises, What influence does chloroform play in the cause of this condition? There is no record of any case where the condition has followed the administration of ether and from this fact alone it is highly suggestive that chloroform plays some part. Mintz, because he found the bacillus coli in the liver of his case, suggests a bacterial cause of the condition. That the colon bacillus should find its way into the liver in these cases is not to be wondered at, and its presence hardly warrants the assumption that it plays any active part in the condition. To my mind it is only a probable coincidence. The toxic theory of the disease is more tenable and helps to explain in some measure the cases following on chloroform administration. It is quite conceivable that the primary toxic agent is the result of faulty metabolism, and in regard to the cases under discussion the presence of chloroform is the crowning factor in the causation of the disease, by which I mean the chloroform intensifies in some way the already active poison.

There are many points of similarity between the symptoms and signs after death from chloroform and those of acute yellow atrophy. Chloroform when taken internally in a poisonous dose produces vomiting, coma, jaundice, and dilatation of the pupils. The post-mortem findings show degenerative changes in the liver cells, heart, and kidneys very similar to those found in acute yellow atrophy. That these lesions are caused by chloroform are amply proved by the experiments of Nothnagel, Toth, Unger, and others on animals. On the other hand, that chloroform is not an essential factor in the disease is proved by the greater majority of the cases of acute yellow atrophy which have occurred where there has been no chloroform used. It is a matter of conjecture whether the symptoms of acute yellow atrophy are part of a general toxæmia or whether they are the outcome of the active changes taking place in the liver. It seems that whatever the source of the poison, its chief effects are exerted upon the liver, heart, kidneys, and brain. That it is a severe cerebral poison is shown by the vomiting, delirium, muscular tremors, dilatation of the pupils, &c. In regard to the treatment much remains to be done. With the exception of one case in the table all the cases ended fatally. In my own case, although similar treatment as that used by Ballin was at once made on realising the condition, yet it was without avail. That cases do recover is quite conceivable considering that in many cases the liver tissue is shown by the microscope to be undergoing repair and it is quite feasible that the individual may be able to overcome the severe toxæmia.

Whatever the cause of this terribly fatal condition is, at present most is theory and conjecture without very much direct proof. Personally the most plausible theory to my mind is that it is a toxæmia arising from the gastro-intestinal tract, and should I ever have a similar case to deal with my treatment, in addition to diluting the poison by venesection and transfusion, would be by the exhibition of intestinal antiseptics.

Cheltenham.

INTUSSUSCEPTION CAUSED BY AN INVERTED MECKEL'S DIVERTICULUM; EXCISION AND END-TO-END ANASTOMOSIS.

WITH REMARKS ON END-TO-END ANASTOMOSIS.

BY LEONARD A. BIDWELL, F.R.C.S. ENG.,
SURGEON TO WEST LONDON HOSPITAL, ETC.

A HEALTHY boy, aged three and a half years, had a severe hæmorrhage from the bowel in June, 1906. He was examined carefully per rectum by his medical attendant but nothing abnormal could be detected. The boy seemed to recover completely and remained well till about the middle of October when he began to have attacks of severe abdominal pain followed by vomiting; these came on at intervals of one week, commencing as soon as the child got up in the morning and passing off within an hour or two, after which he remained quite well till the next weekly attack. On Nov. 21st he had one of these attacks, which, however, did not pass off and was accompanied first by vomiting and then by persistent retching. He was seen by Major E. M. Pilcher, R.A.M.C., who examined him, and finding a hard tumour in the right lumbar and hypochondriac regions diagnosed an intussusception, and recommended an operation. I saw the boy at 5 P.M., six hours after the commencement of the attack. The child was evidently in considerable pain, his legs were drawn up, and his abdomen was rigid; there was no elevation of temperature, but the pulse-rate was 140. He had passed neither motion, blood, nor mucus, although a large enema had been given. The tongue was slightly dry and retching was constant. A well-marked tumour was felt in the right lumbar and umbilical regions but nothing abnormal was detected on rectal examination. The diagnosis of intussusception was fairly certain and I decided on immediate operation.

The patient being under chloroform I opened the abdomen between the outer fibres of the right rectus muscle and found an intussusception which involved the large intestine as far as the middle of the transverse colon. The intussusception was brought out of the wound and was reduced with little difficulty. It was then found that the invagination had commenced in the ileum about six inches from the cæcum. The bowel after reduction appeared black and œdematous but its peritoneal coat seemed all right. No polypus or other cause for the intussusception could be found. It was not thought desirable or necessary to shorten the mesentery or to fix the bowel to the parietes, so the abdominal wound was closed. The patient made a rapid recovery but one week after the operation he had a slight attack of pain rather resembling those which he had before. On Dec. 21st, when he was allowed to sit up and move about in bed, he had another severe attack of pain, and Major Pilcher discovered a well-defined tumour which, however, differed rather from the original one; it was more curved and nearer to the umbilicus and could be moved easily when the abdominal walls were relaxed. The child was in severe pain and was constantly retching. I saw the child a few hours later and reopened the abdomen. The intussusception was brought out of the abdomen and was found to involve the small intestine alone; it was discoloured and measured about four inches. I attempted to reduce the intussusception by kneading and squeezing but without success, so as time was of every importance in so young an infant I did not waste any time in prolonged attempts but decided to excise the mass. The bowel was divided transversely one inch above and one inch below the intussusception, the mesentery was ligatured, and the whole intussusception removed. The cut ends of the bowel were united in the manner to be presently described. The child suffered very little shock and made an uninterrupted recovery. He has had no further trouble. The portion of the gut removed measured eight and a half inches and at the apex of the intussusception was found an inverted and œdematous Meckel's diverticulum. This quite explained the impossibility of reduction.

There are several points of interest in this case; first, the history of weekly attacks of abdominal pain lasting an hour or two and followed by complete recovery; these I believe to have been transitory intussusceptions, as I am sure that a number of cases of slight intussusception are relieved by nature. I have several times been asked to see children supposed to be suffering from intussusception and I have been given a history of a well-defined lump, together with vomiting and the passage of blood and mucus, but when I have examined the case I have detected nothing abnormal. I always consider such cases as cures of intussusception by spontaneous reduction. The second point of interest in this case is that neither blood nor mucus was passed per rectum and that obstruction was complete at once; these points are probably due to the position of the intussusception in the small intestine. The third point was that an inverted Meckel's diverticulum was the cause of the invagination; it is a somewhat unusual occurrence and explains the fact that the intussusception commenced in the small intestine. In connexion with the existence of the Meckel's diverticulum it is interesting to state that the child was born with an umbilical hernia which persisted in spite of pads and appliances and for which I did a radical cure when the child was one year old. A somewhat similar case has recently been reported by R. C. Coffey in the "Annals of Surgery"; it was that of a boy, aged seven years, who presented a similar history of attacks of abdominal pain commencing with melæna and occurring at intervals of one week. In this case the intussusception was entirely ileo-colic and at the operation (36 hours after the commencement of the attack) it was found to be gangrenous.

been very hard pushed to make both ends meet. The graduates of the colonial universities every year tend to more than meet the usual vacancies. It used to be generally believed that, even where there was a large supply of general practitioners in the big colonial towns, there would still be good openings for men who have specialised in such branches of practice as the treatment of eye and ear diseases. This is partially true. There are openings of which good men can take advantage. But as a rule the openings in the colonies for new comers are in country districts where the medical man, besides being proficient in every branch of the profession, must be ready to lead a hard life. It is desirable that every colonial practitioner, intending to start in a country district, should be of good physique and not only able to ride but able to take care of his horses.

There are, of course, certain colonial appointments made in this country particulars of which will be found in our columns. These appointments are sometimes made with permission to practise privately, and sometimes this is not permitted. Candidates for the posts should apply to the Colonial Office for information, and their chances of success will be much increased by having passed through one of the schools of tropical medicine. The duties of colonial medical officers involve medical charge of a district, including as a rule the charge of a hospital and a lunatic asylum. The medical officers also supervise the sanitation of their districts, and as a rule give gratuitous attendance to all Government officials.

The United States of America form a rich and well-populated country to which, as speaking our language, it is natural for the British medical man to desire to go. The regulations for practice in the various States differ much, but it will be found that wherever the social conditions are pleasant and the opportunities for emoluments good there will be plenty of competition. There is an enormous number of medical men in the United States, the proportion of population to medical men in some of the thickly populated centres being not more than 500 to 1. The British medical man contemplating starting in medical practice in the United States will be prudent to make full inquiry before deciding on the locality, and his chance of success will be increased by his having some good introductions.

FRANCE.

The law that regulates the conditions of the practice of medicine in France is that of Nov. 30th, 1892, passed by the Senate and the Chamber of Deputies and signed by Carnot, President, and Poincaré, the Minister of Public Instruction, at that date:—

> No one may practise medicine in France unless he hold a diploma of the doctorate of medicine given by the French Government after examinations duly passed in a State institution of higher medical education.

The fifth article of this law specifically refers to foreigners:—

> Physicians who have taken their degree abroad, of whatever nationality, can only practise in France on condition of having obtained in France the degree of doctor of medicine.

This article was modified by a special decree, signed in July, 1893, referring to certain concessions to be made to such foreigners:—

> Physicians with a foreign degree who desire the French degree of doctor of medicine may obtain partial or complete dispensation of medical study and partial exemption from the examinations required. In no case will candidates be exempted from more than three examinations. Such exemption is accorded by the Minister of Public Instruction on the recommendation of the competent Faculty and the Committee of Public Education.

While this last quotation may be considered the actual state of the law in the formal sense of the word, further and much less liberal projects have since been considered by the legislative bodies and adopted in the form of *arrêt ministériel*, of *circulaire* issued by the Minister of Public Instruction, or of *décret* adopted by Parliament. Presumably too much advantage was taken of the generosity of the concessions of July, 1893, although it must be remembered that the exclusive policy since adopted is by no means aimed at English physicians, but rather against graduates of little-known universities the value of whose qualifications it is difficult to estimate. Be that as it may, in July, 1896, a certain number of exemptions were granted—among whom the writer was fortunate to find himself—and a circular was issued repealing—in substance—the concessions of 1893. No foreign qualifications were to be recognised as deserving of any dispensations and physicians holding foreign degrees and desirous of practising medicine in France were obliged not only to matriculate as medical students but also to produce evidence of having obtained the French diploma of Bachelor in Classical Education (Arts and Philosophy) and the certificate in physical, chemical, and natural science.

The refusal that for the last ten years has almost invariably met the request made by foreign physicians for the right to practise in France is based upon this *arrêt ministériel*. Such requests are answered in the formula—"Depuis 1896, époque à laquelle il y a eu une décision du Parlement, il n'est accordé aucune dispense aux étrangers désireux d'obtenir le diplôme d'etat: ils doivent tous produire le baccalauréat." The simplicity and clearness of this statement make translation unnecessary. This exclusive attitude was not, however, wholly maintained. While withdrawing nothing of the exclusiveness of 1896, the Minister could grant leave to foreigners to possess themselves of a formal academic medical degree which, while it entitled the possessor to call himself docteur en médecine de la Faculté de Paris (de Montpellier, Nancy, Bordeaux, Lille, Lyon, or Toulouse), gave him no right whatever to practise on French territory. To obtain this degree the postulant must formulate his request to the Minister on *papier timbré*, inclosing a copy of his birth certificate, his diplomas, and class certificates, formally translated. This honorary degree is readily obtained and from English candidates it is probable that an appearance in so-called "final" subjects would alone be required.

Up to Dec. 29th, 1906, it was possible to transform the university or academic diploma into a Government degree by becoming a naturalised French subject. On account of the large number of young Russian girls who married in France and thereby became French and claimed the State diploma it has been decided to insist upon the possession by foreigners of the *licence-ès sciences* before this transformation can be granted. The fees for this degree amount to between £60 and £70.

ITALY.

Some years ago the British and American consuls at the great centres of Italian population and commerce combined to form an estimate of the money brought annually into the kingdom and spent within its borders by the English-speaking world. That estimate, an approximate one necessarily, which they carefully checked by every qualifying consideration conceivable, amounted to £20,000,000 sterling, about one-third of Italy's whole revenue at that time. Since then the yearly influx of English and especially of American visitors has greatly increased, so that were a similar calculation to be made now the estimate would doubtless be still larger. This is a fact of great importance from whatever side it is contemplated, and it implies a large and continuous demand for English-speaking practitioners. It is true that of late years an active agitation, having for its object the expulsion of all foreign practitioners from the country, has been carried on by a section of the medical profession in Italy, but the movement has proved only partly successful, the public at large being well aware of the injury which the adoption of such a measure would inflict upon its interests. The British medical men and their American *confrères* form a prominent reason for Italy continually to attract that portion of the travelling public from which she derives so much of her annual revenue. There are therefore excellent reasons why every facility should be offered to them for exercising their calling freely in her cities and health resorts, and we may state at once that the regulations which still exist in Italy with respect to the foreign practitioner are most liberal and fair, it being open to anyone possessing a medical qualification recognised as legal in the country of its origin to engage in practice amongst the foreign visitors and residents within her borders. The restrictions ruling in Switzerland, France, and, indeed, nearly every other European country, do not exist in the Italian kingdom. The medical man's qualification, certified by ability to produce his diploma, is quite sufficient. He has, therefore, (*a*) no examination to pass; (*b*) no fees to pay; (*c*) no Government forms to comply with; and (*d*) requires no previous residence in the country as a "condition precedent" to practise. All the same it will be to his advantage to graduate at an Italian school—Rome, Turin, Pavia, Padua, Bologna, Siena, Pisa, indeed all Italian Universities, grant degrees to duly qualified practitioners who can pass the examination these Universities require. On the other hand, in a country compelled by its financial requirements to impose taxes in every possible direction the English-speaking practitioner has to pay the heavy income-tax ("*ricchezza mobile*" it is called) of nearly 13¼ per cent., At its apex was an inverted Meckel's diverticulum. The treatment was excision of the intussusception, closure of the ends of the bowel, and a lateral anastomosis. The last point is the age of the patient, as I think that recovery after excision of an intussusception is rare under the age of four years.

With regard to treatment, there is little question as to the advisability of early operation when reduction is not spontaneous or is not effected by an enema, since the prognosis depends principally upon the time which has elapsed before the operation. Simple reduction, after opening the abdomen, is effectual in most cases, and the operations of shortening the mesentery or of fixing the bowel to the parietes are liable to produce unpleasant symptoms later. In irreducible intussusception excision is the best treatment; this is combined with end-to-end anastomosis when the small intestine is involved, and with lateral anastomosis and closure of the divided ends when the invagination is ileo-cæcal. It is essential to operate on healthy gut and to divide the bowel at least an inch away from the intussusception on each side. It is also of the utmost importance that the operation should be performed with the greatest celerity.

As I do not know of any published description of the method which I employ for end-to-end anastomosis, I have had some drawings made which will make a description clearer. The method consists of a double continuous suture passed between guides, the adjacent pieces of intestine being held tightly stretched while the suture is passed. In this way contraction of the line of union is impossible. It is performed as follows. Two catgut sutures are inserted—one at the convex border, the other close to the mesentery. These are passed through all the coats of each piece of gut and are tied with their knots on the mucous surface. Both ends of one suture and the short end of the other are clamped, and by pulling these clamps apart the line of suture is tightly stretched; a continuous suture is then run from B to A with the long end of suture B. (Fig. 1.) It is then tied to A and the ends cut off. The piece of bowel is then turned over and two silk Lembert sutures are inserted, one at the convex border and the other close to the mesentery. The one close to the mesentery, *b*, is tied and its short end clamped, the one at the convex border is not tied but its centre is pulled out and it is then clamped (this throws up a definite ridge of peritoneum for the Lembert suture). The two clamps are now held apart so as to put the edges of the gut on the stretch, and with the long end of the suture, *b*, a continuous Lembert suture is run from *b* to *a*. It is tied and its ends cut off (see Fig. 2). The gut is then turned over again and another catgut stitch C, uniting the two ends of the gut on the opposite side of the mesentery, is passed through all the coats of each piece of gut and tied with its knot on the mucous surface. The short end of this is clamped, and this is held apart from the end of the first passed suture B; this makes taut the portion of the circumference of the two ends of bowel between the layers of the mesentery. A continuous suture is then passed from C to B and tied to the end B and then cut short (see Fig. 3). A Lembert suture, *c*, is then passed close to the mesentery and its centre pulled out and clamped. The clamps on the sutures *a* and *c* are then held apart (see Fig. 4) and a continuous catgut stitch is passed from C to A, its two ends being tied to the ends C and A respectively. The Lembert guides *c* and *a* are then tied and one end of *c* and both ends of *a* are clamped and held apart, while a continuous Lembert suture is passed from *c* to *a* with the long end of suture *c* and is tied to one end of *a*. A mesenteric stitch passed a quarter of an inch below the bowel completes the anastomosis.

The main advantage in this method is that the guides absolutely insure that corresponding portions of each piece of gut are united, and as the various portions of the gut are held tightly stretched by the guides during the insertion of the continuous sutures, these sutures can be pulled absolutely tight without any fear of producing subsequent constriction of the new opening. In passing each stitch of a continuous suture it is essential to pull the thread tight and to hold it firmly till the next stitch is passed. This operation as described may appear complicated but it is really simple and it can be done very rapidly (in the case recorded in 14 minutes). It dispenses with the use of all apparatus, such as bone bobbins and clamps, and it combines the advantages of interrupted sutures with the quickness of continuous sutures.

Upper Wimpole-street, W.

A CASE OF PYÆMIA DUE TO THE INFLUENZA BACILLUS, WITH MULTIPLE ARTHRITIS AND MENINGITIS.

BY LEONARD S. DUDGEON, M.R.C.P. LOND.,
BACTERIOLOGIST TO ST. THOMAS'S HOSPITAL; JOINT LECTURER ON GENERAL PATHOLOGY AND LECTURER ON SPECIAL PATHOLOGY IN THE MEDICAL SCHOOL; DIRECTOR OF THE HOSPITAL LABORATORIES;

AND

J. E. ADAMS, M.B., B.S. LOND., F.R.C.S. ENG.,
RESIDENT ASSISTANT SURGEON AND LATE SURGICAL REGISTRAR, ST. THOMAS'S HOSPITAL, LONDON.

WE have thought it advisable to publish a detailed account of this case, inasmuch as we have been unable to find any record of a similar instance of infection due to this bacillus.

The clinical history was as follows. The patient was a female, aged 10 months, born of healthy parents. There was no history of miscarriages. There were five other children in family and all enjoyed good health. There was no history of any recent infectious fever or illness, suggestive of influenza. For two months the mother had observed that this child was fretful and that she was not thriving, though she did not appear to be *seriously ill*, but at the end of the first month it was noticed that the left elbow caused the child pain, and three weeks before admission to the hospital the joint was discovered to be swollen. The swelling was first situated over the head of the radius and the patient was first seen on April 8th last, when there was a tender puffy thickening over the radial head; the following day the swelling had increased in size and fluctuation was readily obtainable; movements at the elbow-joint were not limited, nor were those of pronation and supination, though these appeared to cause slight pain; the case was thought to be one of epiphysitis of the radius, and the mother was told to bring the child for admission. This she failed to do until a week later, when the local state of affairs showed rapid progress of the disease and the child's general condition was very grave. On April 17th, the whole region of the left elbow-joint was swollen, and on the outer and posterior aspect there was a fluid swelling close beneath the thinned and discoloured skin. The skin over the abscess was purplish in colour and not noticeably hot. Movements both at the elbow-joint and at the superior radio-ulnar articulation were abnormally free and caused well-marked grating; in fact, the elbow presented the characters of a flail joint. A skiagram was taken but this revealed no changes in the bones, a fact which will be referred to later. With the exception of some thickening in the neighbourhood of the right hip-joint, the remaining articulations appeared to be unaffected. The general condition of the child was profoundly altered from that observed a week previously, for she now showed the signs of meningitis with marked wasting, head retraction, increased knee-jerks, and frequent vomiting. The pupils were somewhat dilated but they reacted to light, and no squint was observable. No wound or sore was present on the child's limbs. The temperature was 101° F., the pulse-rate was 136, and the respirations were 44. On the day after admission it was decided to open the abscess on the outer side of the elbow-joint, and no anæsthetic was needed for this as the pus was close beneath the distended skin. Thick, creamy, yellow, odourless pus was evacuated and the cavity was found to lead directly into the elbow-joint; a counter opening was made on the inner side of the elbow and the joint was washed out with saline solution and drained with a rubber tube. The pus was preserved in a sterile test-tube for bacteriological investigation.

The child's condition steadily grew worse, there was persistent vomiting, the head retraction became more marked, and a squint was observed on the third day. On the evening of this day the temperature reached 105°, the pulse-rate was 160, and the child had slight diarrhœa. The temperature fell to 100° on the next morning but the condition was not improved and lumbar puncture was performed with a view to the relief of the meningeal symptoms. This, however, was not successful, as the needle only withdrew a drop or two of cerebro-spinal fluid, and the child died about four hours later. This fluid was also preserved in a sterile tube.

Report of post-mo *(performed by Dr. W. O.*

commence hospital work; at the end of the tenth semester he may present himself for the second theoreticum. This and all other examinations (altogether three in number) are both practical and theoretical, and must be completed within eight days. It comprises internal medicine, surgery, and pathology, whilst the third and last examination comprises gynæcology, obstetrics, hygiene, materia medica, and ophthalmology; pediatrics, otology, dermatology, and laryngology are examined in alternately. This last examination the student is expected to pass not later than five years after the first, otherwise he has to present himself again for certain subjects of the first examination, especially anatomy. The fees for the three examinations are £15, and then comes the fee of £6 5s. for the degree of M.D., without which degree nobody is allowed to practise. The fees for the lectures are about £35 for the five years, and about £15 for special classes may be added, so that the entire cost of obtaining the degree of M D. would be from £70 to £75. All the universities confer the degree of M.D., and no distinction is made here as regards the place where the title has been gained, although the University of Vienna is most favoured because it offers the best opportunities for studying. In special cases the Minister of the Interior may allow a foreign qualification to be recognised as entitling its holder to practise, only a mere formal examination being required; such a special order is, however, very difficult to obtain. The examinations are entirely oral and are conducted in various languages according to the locality—namely, German in Vienna, Innsbruck, Graz, and Salzburg; German and Bohemian in Prague, and Polish in Cracow and Lemberg. These seven universities are the only ones in Austria, and only they may grant degrees, as the medical schools are invariably integral parts of the universities. If a British medical man wishes to practise in one of the frontier spas or in Karlsbad he will have little difficulty in obtaining permission to do so if he applies for it, especially if he gives an assurance that he will only attend his fellow-countrymen and only for the season. He need not then obtain official recognition of his diploma.

As regards Hungary, the medical curriculum is for practical purposes similar to that in Austria, and the foreigner whether a holder of a diploma or a student who wishes to practise legally, must become a naturalised subject and must pass the three above-mentioned examinations in the Hungarian language. Applications for admission must be addressed to the Minister of Education, who decides upon the conditions of admission after consultation with the medical faculty of Budapest. Usually the applicant has to pass three medical examinations after having proved his qualification for admission by a Maturitätszeugnis, or testimonial of sufficient preliminary instruction in two classical languages, chemistry, arithmetic, geometry, and physics. The total fees amount to 295 kronen (about £12), and the fee for "promotion"—i.e., for the M.D. degree—is similar to that in Austria. Besides the university in Budapest there is another university in Klausenburg for which the same rules hold good. Only these two universities may confer medical degrees in Hungary.

DENMARK.

In Denmark only those who have passed the Danish Medical Examination are entitled to practise and in Iceland it is necessary to have been examined at the Medical School in Reykjavik. *The medical student* before beginning his studies must present a diploma of *examen artium*—an examination very similar to the German *Abiturientenexamen*. At the close of the first year he must pass an *examen philosophicum*. The medical studies proper require from five to six years. The foreign student will find one agreeable difference from what is customary in other countries—namely, that all University lectures and clinical courses are free, payment of class fees being unknown, but a few pounds are required for the examination. On passing the examination the young man becomes entitled to practise, and not a few commence at once. The *majority*, however, prolong their practical training by accepting an appointment as (salaried) junior house physician or house-surgeon in one of the numerous hospitals of the country. The most highly valued appointments—namely, those at the Kommunehospital or Royal Frederic Hospital of Copenhagen—are, however, in so great demand that not rarely four, five, or even more years elapse before an aspirant can secure the coveted position, when he serves for one or two years in the different departments of the hospital.

The only academical degree for medical men known in Denmark is the degree of M.D. It is granted exclusively by the University of Copenhagen, and only to those who have submitted to the faculty an original investigation of undoubted scientific value, the consequence being that only a comparatively small number of Danish practitioners possess the degree in contradistinction to what is customary, for example, in Germany. In fact, the Danish degree of M.D. must be considered as equal to the German title of *privatdozent* or the French title of *professeur agrégé*, as it authorises its possessor to teach publicly in the university.

The only portions of Danish territory where a foreign medical man is permitted to make use of his diploma are the Danish islands in the West Indies, the Governor being empowered to grant such permissions; but he is not likely to do so except during epidemics or when other abnormal conditions obtain.

NETHERLANDS.

A medical practitioner holding British qualifications cannot practise in the Netherlands without being also qualified in the Netherlands. For this purpose it is necessary to pass the medical examinations of one of the universities.

SWITZERLAND.

Foreign practitioners must pass the first, third, and fourth State Examinations. These examinations are held in either French (at Lausanne and Geneva) or German (at Bern, Basel, and Zürich). In addition to the British five years' curriculum practitioners would require one or two years' additional study. The examination fees amount to about £9.

SPAIN.

To practise in Spain or her colonies it is necessary for the holder of British qualifications to send his diplomas to the University of Madrid. After inquiries as to identity a diploma will be sent to the applicant who can then legally practise on the same conditions as a Spaniard—namely, the payment of certain duties.

PORTUGAL.

Holders of foreign diplomas must apply for examination at the schools of Lisbon or Oporto or the Faculty of Coimbra. The cost of the examination, including the diploma, is about £50. For the last examination the presentation of a *printed* dissertation is required.

TURKEY.

Every foreign medical practitioner desirous of settling in Turkey for the purpose of practising his profession must undergo the ordeal of the so-called "colloquium." This is a sort of professional examination very easy in itself but a source of annoyance and vexation to Europeans by the dilatory propensities of orientals and their habit of conducting business in an indolent and easy-going way. The "colloquium" itself takes about half an hour's time, whereas the preliminary steps and arrangements and the subsequent formalities necessary for the final obtainment of the medical permit lasts for weeks and even months. The "colloquium" must at the present time be passed either in French or Turkish without any interpreter, the choice of the language being left to the examinee. The possessor of a foreign diploma is tested, as a rule, in four subjects and the testing consists in three or four questions in each subject, which the candidate has to answer orally. It has not yet happened that a European physician failed to pass the "colloquium." The fee for it is about £8 and there are in addition some registration expenses.

RUSSIA.

The law relating to foreign medical practitioners desirous to practise in Russia is contained in the two following paragraphs of the *Vratchebny Ustav* or medical statute:—Section 93 (*a*): No one, whether a Russian subject or a foreigner, who has not a diploma or certificate from a university or from an Army Medical Academy, has the right to follow any branch of medical or veterinary practice in Russia; (*b*) foreign medical practitioners who wish to practise medicine in Russia must, without exception, know the Russian language. Section 94: Of foreign practitioners who shall be invited or who may come to Russia the right to decide which of them shall be permitted to free practice here and under what conditions is in the hands of the Medical Council of the Ministry of the Interior; some shall be permitted only after the usual examinations and consequent granting to them of a learned degree; others more distinguished after an oral examination in the Medical Council; lastly, others who have

* Two hours after food. † Five hours after food. ‡ Count made from an unsatisfactory film.

fasts. The pulse became softer and weaker but remained regular in rhythm. The arterial pressure gradually sank so that at the end of the fast the fall amounted to almost 25 per cent. of the normal reading. On taking food this fall was soon made up, and by the end of the first week of feeding the pressure was practically normal again. Luciani, using a Von Basch instrument, found that the pressure on the radial artery of Succi fell from 22 to 12 cubic centimetres of mercury during a fast of 30 days. The blood changes are not very definite. For the first few days the hæmoglobin remained almost unaffected but towards the end of the first week it commenced to fall and thereafter fell steadily. This reduction persisted for several days after food was taken. The red corpuscles varied somewhat from day to day, but on the whole no striking effect was produced. The stained films showed practically no alteration in size, shape, or staining properties. In the last four days a few nucleated red corpuscles were observed. Neither Luciani nor Senator record having observed nucleated red corpuscles, but both agree that the hæmoglobin and number of the corpuscles vary from day to day. Senator accepts Luciani's suggestion that the number of the corpuscles probably does not alter much, but that the variation depends really upon the amount of fluid consumed. In Luciani's case the water consumption varied from day to day and he was able to show that the blood condition corresponded to the water consumption. In my patient the daily consumption of water remained constant, but the man was allowed to suit himself when he took the water except on certain days. The hæmoglobin did not correspond with the red blood count and probably indicates a true diminution. In the case of Succi, Luciani found that in the first week the white cells fell from 14,540 to 860, while the leucocytes became smaller in size. Thereafter the number rose again to 1500 and remained about this figure, while the cells regained their normal size and appearance. The Senator-Müller counts record a much less profound diminution. My enumeration, on the other hand, indicates a slight leucocytosis. There was certainly no manifest diminution in size of the individual cells. The differential counts are chiefly remarkable for the gradual increase in the percentage of eosinophyl cells. I cannot find any note about this point in human blood, but Okintschitz notes a similar increase in the case of starved rabbits. He found that the polymorpho-nuclear cells and small lymphocytes diminished while the eosinophyls and large mononuclear cells increased during absolute starvation with deprivation of water. The opsonic index of the blood for staphylococcus and bacillus typhosis was also investigated. Table II. shows the result.

TABLE II.

Date.	—	Staphylococcus.		Bacillus typhosus.

6/2/07		11·0	12 0		

The figures given represent the average number of organisms taken up by a polymorpho-nuclear cell. To obtain this average 30 cells were counted. A fresh emulsion was used each day and this explains the variation in the average number. As a rule the blood was drawn off in the afternoon and in each case was tested against my own serum drawn off at the same time and examined under similar conditions. For estimating the power of the sera my own washed corpuscles were used. The general result is that no alteration can be detected during the fasting period. The serum in my patient remained as active as my own. This is interesting as the man informed me that he had never suffered from a cold or other infection during his various fasts, though he always felt very chilly and had difficulty in keeping himself warm.

I have not been able to find much work bearing upon this point. Canalis and Morpurgo investigated the effect of starvation on pigeons and rats to determine whether they were thereby rendered more susceptible to anthrax. They found that pigeons lost their natural immunity to anthrax after fasting 6–7 days but regained it again on taking food. Hens previously rendered immune by injections of anthrax cultures did not lose this acquired immunity through starvation. Similarly rats remained immune despite starvation. On the other hand, untreated hens starved for from three to seven days succumbed more readily to inoculated anthrax. Roger and Josué tested the resistance of rabbits against the bacterian coli. They found that absolute starvation for 3–7 days followed by feeding gave an incre ing power applicants for registration must be members of an incorporated medical body in Canada giving similar privileges to persons incorporated in Manitoba. Application should be made to the Council by British medical men desiring to practise in the province. Licences to practise are issued to women upon the same terms as men.

Alberta.—Medical practitioners must be registered by the Council of the "College of Physicians and Surgeons of the Province of Alberta." The Council admits to the register anyone who (1) produces a diploma of qualification from any college or school of medicine and surgery which exacts for such diplomas attendance on at least a four years' course of lectures of at least six months each; (2) gives proof of identification; (3) passes before them a satisfactory examination appertaining to the profession of medicine and his fitness and capacity to practise medicine, surgery, and midwifery; and (4) pays $50, and another $50 for registration.

Saskatchewan.—No one may practise in Saskatchewan unless registered (fee $50) by the Council of the "College of Physicians and Surgeons of the Province of Saskatchewan." The Council admits to the register anyone who produces a diploma of qualification from any college or school of medicine and surgery recognised by the Council, which requires attendance at a four years' course of lectures, and who passes an examination (fee $50) before the Council.

AUSTRALIA.

Legally qualified British medical men can practise in all parts of Australia. Proof of registration by the General Medical Council of Great Britain must be submitted to the medical board of the particular State selected, when a certificate to practise is granted. The medical man with British qualifications who desires to practise in Australia must communicate with the medical board as soon as he intends to settle, so that he may regularise his position from the beginning.

NEW ZEALAND.

Registration in the colony of New Zealand is obtained by the legally qualified British practitioner on producing his proof of registration by the General Medical Council of Great Britain and on paying a fee of £1 5*s*.

BRITISH SOUTH AFRICA.

The position of the legally qualified British practitioner in South Africa is much the same whichever colony he proposes to practise in.

Cape Colony.—No person may practise in Cape Colony as a medical practitioner without a licence signed by the Colonial Secretary of the province and the recommendation of the Colonial Medical Council is required. The fee for the licence is £5 and women are eligible for the licence. Applications should be made to the Colonial Medical Council at Cape Town.

Natal.—Here also application for a licence to practise medicine in the colony must be made to the Colonial Secretary of the province. The application will be granted upon the approval of the Natal Medical Council and the fee for registration in Natal is one guinea.

Southern Rhodesia.—The admission fee for the practice of medicine in Rhodesia is £5 and application for the licence should be made to the Administrator of Rhodesia at Salisbury, Rhodesia. It would be well also to write to the Secretary of the British South Africa Company, London Wall, E.O.

Transvaal and the Orange River Colony.—The Transvaal Medical Council (Pretoria) and the Medical and Pharmacy Council of the Orange River Colony, Bloemfontein, grant a licence to practise on payment of £10 and £7 10*s*. respectively. Proof of registration by the General Medical Council of Great Britain must be supplied.

THE COLONIAL MEDICAL SERVICE.

In the following countries there are medical departments regulated from the Colonial Office:—British Guiana, Jamaica, Trinidad, Tobago, Windward and Leeward Islands, British Honduras, Fiji, Ceylon, Straits Settlements, Federated Malay Straits, Hong-Kong, Mauritius, Seychelles, Gibraltar, St. Helena, Falkland Islands, Uganda, Gambia, Sierra Leone, the Gold Coast, Lagos, and Northern and Southern Nigeria. The last six of the countries enumerated have been formed into the West African Medical Staff, a definite and well-organised service. The particulars of the Colonial Medical Service were published in full in THE LANCET, April 29th, 1905, p. 1151, and all information concerning any vacancies in the service can be obtained from the Colonial Office.

Looking Back.

FROM

THE LANCET, *SATURDAY*, August 29th, 1829.

FLEXIBLE STETHOSCOPE.

To the Editor of THE LANCET.

SIR,—It having been suggested to me, that notice of a modified stethoscope, which has been successfully used in the Royal Infirmary, Edinburgh, would perhaps meet your eye from another pen, if mine were not employed, I beg leave to trouble you with a description of the following instrument. I should not, however, have had the hardihood to obtrude this letter on your notice, had not others, as well as myself, been experimentally satisfied of the truth of the details herein made.

Convinced of the pathological and practical utility of the stethoscope, I have often regretted the great difficulty of attaining accurate knowledge by it, notwithstanding the numerous cases of thoracic disease that have been treated in the Royal Infirmary. This difficulty arises from the great number of medical students in Edinburgh, and who, from their anxiety to attain facility in auscultation, are often denied permission to use the instrument, in consequence of the torture unavoidably inflicted by repeated attempts, and by the frequent changes of posture necessarily required of the afflicted patients. To alleviate the sufferings of the sick, aggravated by the interposition of a timber cylinder between the diseased thorax, and the closely-applied head of the examinator, and, with the exception of the portion in contact with the bed, to enable students to explore any part of the chest of any diseased person, *in any position*, and in any stage of disease, without pressure or inconvenience to the patient or to themselves are the objects which I have had in view, and obtained by means of a stethoscope of the following kind:—It consists of two tubes, each seven inches in length, and 5-8ths of an inch in diameter, except at the part to be applied to the thorax, where the diameter of the aperture is an inch and a half. These pieces are united by a perforated joint, three inches in length, placed at right angles to their extremities, and fitting into the tubes in the same manner as the joints of a flute are united. They thus permit the main limbs of the stethoscope to form any required angle. The upper end of the instrument is provided with an ear-piece, sufficiently large and concave to envelop the ear. The ear-piece, by means of a moveable joint, can be placed in any necessary direction with respect to the extremity of the tube. The moveable joints are, by a simple contrivance, rendered perfectly air-tight. The whole instrument is, in a word, a bent tube.

The following are the advantages it affords:—It conveys at an angle distinct thoracic sounds. It can be applied perpendicularly to any point of the chest, while the angular form precludes the inconvenience of pressure. The auscultator can use it in the sitting posture, with his head seldom deviating from the erect position, and, in some cases, without disturbing the patient while asleep. As it does not require the head of the stethoscopist to be over the chest of the sick person, and as another tube can be screwed to the instrument, so as to lengthen it, it can be used in the highest ranks of society, without offending fastidious delicacy. Every portion of the thorax, except the part in contact with the bed, can be explored, while the patient and the feet of the examiner remain at rest. Should the patient assume the sitting posture, though his bed be accessible at only one part, every portion of his chest can be explored with perfect ease to both parties; with a longer stethoscope, the auscultator can explore every portion of his own thorax. The instrument can be lengthened or shortened at pleasure. The third tube is otherwise useful. Timidity or disgust is unpardonable on the part of a physician when engaged in the discharge of his duty. But as it is often necessary in contagious diseases to explore the chests of the poorest individuals, reasonable precaution may be so far complied with as to use the cylinder with the additional tube, in cases manifestly contagious, or miserably wretched. Finally, with a view to portability, it is not necessary to disjoint the instrument, unless the third tube be employed, as the limbs will lie in a parallel position with the extra tube interposed, and become conveniently portable in a small case or bag.

hygienic conditions do not play a very important rôle. In Glasgow for the most part all the cases have occurred amongst the poorer classes (one and two room and kitchen houses), but seldom amongst the very dirty or uncleanly, and I am not inclined to the view that insanitary conditions generally play a prominent part in the spread of this disease. Soil and situation are likewise of no importance. It is true one is occasionally furnished with a history that the child is in the habit of playing amongst the dirt, as children are wont to do, and of occasionally placing their dirty fingers in their mouths or conveying thereto articles of food, buttons, cigarette ends, dumb teats, &c., from the ground or floor, but this occurs by no means on all occasions and would not explain the sickness of infants solely breast-fed, older children, adolescents, and adults.

I have seen a large proportion of the cases in Glasgow and in all instances every possible contributory factor has been carefully inquired into. The food and habits of each member of the family in which a case has occurred have been investigated and nothing of importance has been elicited. Even bananas and other kinds of fruit and sweets have borne a similar fate. Cats, dogs, and canaries have been encountered occasionally in the houses of the sick, but no connexion could be established. It has been suggested that old clothes may carry infection. There is no evidence in support of this view in connexion with the Glasgow cases, and pawn tickets have seldom been found in any of the houses during the process of disinfection. Professor Symmers[2] noted that in five cases which ended fatally the small intestine was reddened with capillary engorgement and the solitary follicles were enlarged and in places bright red, revealing the condition often seen in acute pneumonia and in Asiatic cholera; and the mesenteric glands were enlarged and congested. It is not suggested that this organism is constantly present in the bowel, but it may be an occasional habitant therein, and certainly the post-mortem conditions above mentioned would seem to indicate that it might be isolated from the fæces of recognised cases if sufficient care and labour be expended. The meningococcus has been isolated from the blood of recognised cases of the disease by Elsner and others. It may therefore be found in the urine and possibly also the fæces. It is well known that diplococci are normally present in the alimentary tract of man, horses, and other animals; a little further research in this field might furnish more light on the subject. In connexion with those families in which multiple cases did occur in Glasgow the carelessness in dealing with fomites and fæcal discharges was strikingly manifest. The fomites in those instances impressed one as the chief source of infection. The theory which I have advanced resolves itself into this query: *Is the meningococcus a constant or occasional habitant of the bowel of man, horse, or other animal, assuming pathogenic properties under certain conditions and especially so in abnormal situations such as the meninges?* We already know several instances of such—e.g., bacillus coli, bacillus enteritidis sporogenes, streptococci and staphylococci, &c.

Predisposing causes.—Coryza has been observed to be present previously to onset of illness in some instances and tonsillitis rarely. In several instances throughout the illness a definite watery and sometimes muco purulent nasal discharge occurred, but in a large majority of cases the nasal tract was rather dry than otherwise.

Incubation period.—Although this has been conceded by some authorities to extend to three or four days it may be accepted as very difficult to determine. In point of fact no very definite statement can be made on this subject. Of the cases which occurred in Glasgow, in which two or more persons sickened in one family as already stated, the interval between sickening and removal to hospital of the first case and sickening of the second varied between one and ten days. It does not follow, however, that this varying interval is to be accepted as the incubation period of cerebrospinal fever, because it is just possible that the second case may have obtained its infection from the same source and at the same time as the first case, although the onset of the disease appeared at a later period. In support of this view it is already known that the micro-organism has been found in the nasal secretion of healthy attendants on the sick who subsequently did not develop the disease, and, further, that it may be that in those who did develop it a variable time was necessary for the passage of the micro-organism from the nose to the meninges.

History and symptoms.—The history usually furnished is to the effect that the child went to bed well and wakened early in the morning with a highly nervous condition, complaining of severe frontal headache and vomited, or having been previously quite well took a rigor and vomited. Vomiting and a severe frontal, occasionally occipital, headache are invariably the first symptoms. Vomiting is usually more or less continuous throughout the first and sometimes the second and third days. The onset of illness, therefore, is frequently sudden, may or may not be preceded by rigor, and is followed by a violent discharge of nervous symptoms. In fulminant cases, from a condition of extreme restlessness, irritability, and general hyperæsthesia, the patient becomes delirious, and, in rare instances, maniacal, young children frequently developing convulsions and dying whilst in them or after coma has set in. The duration of illness in those cases has been as short as five hours, occasionally 24 hours, and usually a few days only. A large number of cases, however, are not so acute, in that the stage of irritability is more prolonged, lasting over several days, and they furnish a more striking picture of meningeal mischief. The symptoms then seen embrace grinding of the teeth, twitching of the angles of the mouth, one arm or hand, or convulsive movements of both hands and legs, "rolling of the eyes, squint, irregularity of the pupils (contracted or dilated) which may not, or only sluggishly, respond to light, photophobia, and diplopia. Conjunctivitis is by no means so common as some observers suggest and when present is usually accompanied by a slight purulent discharge resulting occasionally in matted eyelids. Nystagmus occasionally is met with. The tongue is usually very foul and occasionally the teeth are covered with sordes."

Tinnitus aurium is sometimes complained of in older subjects. Difficulty in hearing properly or absolute loss of hearing and sometimes unbearable pain in the ear or discomfort at the slightest noise are all encountered. The joints, especially the knee-joints in rare instances, are swollen and painful, and in the absence of other well-marked meningeal symptoms a diagnosis of acute rheumatism might be made. Perspiration of the head is sometimes noticed, especially in rickety children. Patients sometimes moan and shriek with pain, especially when touched. Retraction of the head is very common; in milder cases, however, only tension of the muscles of the back of the neck is to be observed and is well brought out when an attempt is made at bringing the head forward in order to touch the breast with the chin. Severe pain in the back of the neck is then complained of and the muscles are seen to stand out in relief. Occasionally also in so doing spasmodic contractions and muscular tremors are set up elsewhere and rarely convulsions. All degrees betweeen slight tension of the neck muscles to marked cervical opisthotonos are met with in different cases.

It is to be remembered that infants and young children usually lie with the head set well back in health and it is just possible that in asking this question from the mother the physician might readily be misled. It is always advisable therefore to take nothing for granted and to examine the neck for yourself. Tenderness of the spine is also a common feature of this disease and in severe cases opisthotonos may be present. In very severe cases this may be so marked, as after placing the child on his back on a table it will be seen that the body rests only on the occiput and buttocks, the arch of the spine being so great as to permit the hand readily between it and the table without touching. I recollect seeing a case with the occiput set firmly against the buttocks.

Characteristic attitude.—The patient usually lies on the side with the head retracted, forearms flexed, occasionally exaggerated pronation, thighs flexed upon the abdomen and the legs on the thighs. It is to be noted, however, that this perfect picture is far from being a common one, and in ordinary less severe cases the child may assume many attitudes throughout the day during its restless periods. The reflexes are variable, often exaggerated, sometimes absent. Usually ankle clonus is absent but by no means always.

Kernig's sign.—Much importance has been attached to this phenomenon, which, however, is common to all forms of spinal meningitis. When the hip-joint is semi-flexed in health the leg can be extended upon the thigh nearly in a straight line, but if spinal meningitis be present the attempt to extend the knee produces painful spasm of the hamstring muscles. Fever is always present but may be intermittent.

---

[2] Professor Symmers: THE LANCET, Feb. 23rd, 1907, p. 508.

Narrow Escape of Professor Rossoni.

The Roman school was within an ace of losing its distinguished professor of medical pathology on August 16th. Dr. Eugenio Rossoni had driven to the Villa Umberto with the Baroness Hüffer and on alighting from his carriage at the Galleria Borghese was saying a few parting words to her when a bicyclist in full career knocked him down. The professor promptly regained his feet, but had sustained a severe blow on the left temple, from which the blood was flowing profusely. He assured the Baroness that the wound was trifling, but all the same was immediately conveyed in his carriage to the Policlinico where he was at once attended to by Professor Alessandri, assisted by Professor Ascoli and Dr. Maffi. He was found not only to have been wounded in the temple but to have sustained abrasion of the left palpebra, as well as several contusions on the left leg and on the hands. There was fortunately no sign of internal injury; so after being duly cared for by his colleagues above mentioned he was conveyed to his residence, where, on the next morning he was found by Professor Alessandri to be doing well. This is by no means an isolated instance of the dangers incurred in the capital of Italy by reckless cycling and motor driving—dangers recalling the risks to life denounced in the Third Satire of Juvenal as all too common in the Rome of the first century.

August 24th.

Obituary.

WALTER HENRY BROWN, F.R.C.S. IREL.

ON August 12th Mr. W. H. Brown died at Highfield House, Headingley, Leeds. During his professional career he had three or four attacks of blood poisoning, the last three and a half years ago, since which he never regained his usual state of health and suffered from chronic colitis associated at times with agonising pain and partial obstruction. In July, 1905, the obstruction was complete for five days and an operation was arranged, but the night before this was to be performed he obtained relief, and from that time never had any obstruction. At the end of three months he appeared so much better that he commenced his hospital and private work again. Those who saw him know how bravely he tried to do his work. In December of last year he was persuaded to resign his position of surgeon to the infirmary. In accepting his resignation the infirmary board passed the following resolution:—

> That in accepting Mr. W. H. Brown's resignation of his position as honorary surgeon to the General Infirmary at Leeds the weekly board desire to place on record their appreciation of the great services which Mr. Brown has rendered during the period of his association with the infirmary, and in particular during the 16 years that he has held the post of honorary surgeon. Conspicuous for his interest in his patients and his care for the honour of the infirmary, he has also won high esteem from his colleagues on the weekly board, and the faculty, and from the members of the staff of the institution. The weekly board desire to express their great sympathy with Mr. Brown in his inability to bear the double strain of his public and private practice, but hope that now he is relieved from his heavy duties at the infirmary he will speedily regain his full health and strength.

The wish expressed at the end of the resolution was unfortunately never realised, for at the end of January last he gave up all ideas of practice and from that time till his death spent the greater part of his time in bed, nursed by a devoted wife and nurses who had worked with him at the infirmary. They did everything in a most indefatigable manner to relieve his sufferings which at times were intense. Their attentions were the admiration of his colleagues who had the melancholy duty to look after him but who could do so little for him.

Mr Brown was only 50 years of age when he died. He was educated at the Leeds Grammar School under Dr. Henderson, afterwards Dean of Carlisle, and became a close friend of his family, and during the illness of his old master he was many times called to Carlisle in consultation. His medical education was at the Leeds School. Amongst his teachers were Professor T. Clifford Allbutt, Mr. S. Hey, Mr. C. G. Wheelhouse, Mr. T. Pridgin Teale, and Mr. T. R. Jessop. Mr. Brown obtained the M.R.C.S. Eng. in 1878 and the F.R.C.S. Irel. in 1887. The honorary degree of M.Sc. Leeds was conferred upon him in 1905. It was at the Leeds Infirmary that his work was principally done. Appointed assistant resident house surgeon there in 1877 he completed a year's office, and was then appointed house surgeon to the West London Hospital in 1878, where he had the advantage of working under Sir Alfred Cooper, Mr. H. T. Butlin, and other distinguished surgeons, who were at that time on the staff. The next year he was appointed resident surgical officer to the Leeds Infirmary. Four years later he commenced practice in Leeds, and was elected one of the honorary surgeons to the Leeds Public Dispensary. In 1885 he was elected as assistant surgeon to the Leeds Infirmary and subsequently surgeon. He held the office for 16 years, and in January last he was placed on the consulting staff. During these years at the infirmary his best work was done and some of the progress which surgery has made was due to his originality. As a teacher he attached much importance to instructing the students in the common things of everyday surgery, and always impressed upon them that it was the minor accidents and ailments with which they would have to deal, to a great extent, in the future. Mr. Brown was a frequent contributor to our columns of interesting surgical observations. We may instance the case of gastro-enterostomy published in THE LANCET of July 7th, 1900, in which at the end of ten days the stomach opening was found closed by a membrane, a condition which led to some important modifications in performing the operation. The case of intussusception, caused probably by a round worm, recorded in THE LANCET of Sept. 16th, 1905, illustrated his persevering methods. He removed the intussusception and made three attempts before he succeeded in restoring the continuity of the bowel. A paper on Continuous Transfusion as a Means of Preventing Shock in Prolonged Operations, which also appeared in our columns, was a valuable contribution to the subject, while cases of plastic surgery shown at the recent Oxford meeting of the British Medical Association demonstrated his skill in this branch of surgery. He took the keenest interest in the management of the infirmary, and some of the improvements which he suggested are worthy of mention, such as the alteration in the heating and ventilating of the operating theatres and the building of the new balcony for the open-air treatment of the children.

Mr. Brown was an enthusiastic lover of his profession and the dominant note in his character was his sympathy and kindness; nothing was too much trouble to secure the comfort of his patients, and this kindly feeling endeared him to them and a large circle of friends. His body was buried at Lawnswood Cemetery on August 14th in the presence of a large gathering of lay and professional friends, by whom his death at a comparatively early age was sincerely regretted. He leaves a widow, one son, and one daughter, having celebrated his silver wedding in the earlier part of this year.

Medical News.

PLAGUE REPORTS.—The Department of Public Health of Queensland in a bulletin dated July 13th reports that on July 6th one case of plague was notified in Brisbane. The patient was a young man, aged 18 years, who died in the plague hospital on the evening of July 6th. Till the occurrence of this case no case of plague had occurred in Brisbane since May 31st. With reference to the Cape Colony, six cases of plague occurred in natives at two localities within seven and 12 miles respectively of King William's Town during the week ended August 3rd.

DEATH OF A CENTENARIAN.—The *Times* states that the death has occurred at Athea, county Limerick, of Mrs. Sullivan, *née* Dalton, aged 101 years. Her life was entirely spent in the parish of Athea and she had enjoyed good health, being able to attend the services at the Roman Catholic church up to April last.

Births, Marriages, and Deaths.

BIRTH.

TURTLE.—On August 25th, at 18, Cambridge-terrace, Hyde Park, W., the wife of Godfrey de Bec Turtle, M.D., of a daughter.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

opportunity is taken of confirming the diagnosis made. The operation is a very simple one and if carried out with the usual precautions is attended by no risks whatever.

Differential diagnosis.—Meningitis may be a complication of many diseases—namely, pneumonia, influenza, enteric fever, glanders, plague, tuberculosis, and extension from middle-ear disease, &c. In those other diseases, however, a previous history of sickness will be furnished, and the clinical symptoms of the particular disease should be evident before extension to the meninges has occurred. In making an examination of a suspicious case of cerebro-spinal fever the lungs should always be examined and pneumonia eliminated. In young children I agree that this is sometimes difficult, but the embarrassed breathing and disturbed pulse-respiration ratio should be of great assistance in arriving at a diagnosis. In cerebro-spinal fever the pulse-respiration ratio is unaffected, and the respiration is seldom laboured as in pneumonia. A diagnosis from influenza is probably the most difficult, but even here the history should be of value, and great pain in the joints is uncommon in cerebro-spinal fever. Tuberculous meningitis has generally a more gradual onset, a less violent headache, and a more regular course than cerebro-spinal fever. Otitis media with extension to the meninges should present little difficulty as a previous history of a discharge from the ear will be given. When called upon to see a case of cerebro-spinal fever it is my universal practice to refrain from examining the patient until I have written down the history after careful cross-examination of the parents, and what strikes one most in connexion with almost all the cases of cerebro-spinal fever with which we have had to deal in Glasgow is the sudden onset, intense frontal or occipital headache and vomiting more or less continuous, followed by great irritability and general hyperæsthesia. I know of no other disease presenting such a picture as one usually meets with, where the patient, previously well and fit, is so suddenly struck down without previous warning, becoming soon after very ill and usually delirious.

Conclusion.—In the past many deaths in Glasgow, as elsewhere, have been certified as simple meningitis, idiopathic meningitis, acute meningitis, occasionally septic or suppurative meningitis, or posterior basal meningitis. I have had difficulty in understanding what is meant by simple or idiopathic meningitis. I have always wondered, as doubtless others have wondered, what caused the meningitis, and in the absence of any other definite information as to what is the true causative micro-organism I feel justified in concluding they should fall within the category of cerebro-spinal fever. I am not one of those who attach any importance to the term "simple" or "idiopathic," and prefer to put the query, What caused it?—as undoubtedly there was a cause. Acute, septic, suppurative, and posterior basal meningitis for the same reason must now be relabelled "cerebro-spinal fever." Further, I believe that some cases certified in the past as tuberculous meningitis were really cases of "cerebro-spinal fever." In order to satisfy myself on this point I have inquired into the history of some of those cases and have been told that the child had only been ill for periods varying between two, four, and six, days. Other deaths also have been certified as due to "teething and convulsions." I put the question to you, gentlemen, Does it conform to any of the laws of nature that a child should die because it is getting teeth? I have difficulty in understanding this also, and in the absence of further information I am inclined to the view that at least some of those cases are also cases of cerebro-spinal fever. Further, it is conceivable that some deaths registered as due to "acute gastritis" and probably also "summer diarrhœa" may really be actual cases of cerebro-spinal fever.

Glasgow.

THE TREATMENT OF CANCER.

BY LOVELL DRAGE, M.A., M.D. OXON.,
MEDICAL OFFICER OF HEALTH, HATFIELD RURAL DISTRICT, ETC.

IN the year 1902 I published a paper in THE LANCET[1] calling the attention of the medical profession to the amelioration in the condition of patients suffering from cancer by the artificial production of what is technically known as leucocytosis, which denotes an increase in those cells of the blood which are most highly endowed with the properties of living cells. The first agent used for the purpose was the cinnamate of sodium, and I was led to use the drug because of clinical observations previously made upon patients suffering from cancer and who were treated with the oil of cinnamon. With the aid of my friend, Mr. G. T. Morgan, D.Sc. Lond., of the Royal College of Science, South Kensington, I have since then made an attempt to test various other organic salts closely related to the cinnamate of sodium.

Several papers referring to the results of the treatment have been published in the two principal medical journals, and it will be well to analyse the reasons why, after so many years of uphill work, no convincing results have been obtained. Surgery, so far, has held the field in a manner which is surprising to one like myself who, after 23 years of professional life, has known no permanently successful result secured by surgical methods in the treatment of this disease among patients, friends, or acquaintances. The failure of surgery is to my mind absolute, although all cases, except the worst possible ones, are included in its net. It is expected of anyone who challenges the surgeon, as I do, to compare results from cases of every degree of advancement in the disease, up to the worst, with those obtained from cases of the most favourable kind. The only four early cases which I have been able to secure have all succeeded. It is true that in one case the growth was removed by the knife, but the operation of simple removal was one which surgeons call criminal because of its want of completeness. Criminal or not, the patient remains well and at work after more than six years, when according to the rules of surgery she should have died long ago, or at all events been incapacitated from earning her living. One alone of the four is dead, and death was caused by heart disease after the complete disappearance of the growth. Another case, that of a nurse who refused operation, remains well and at work after four years, after fearing that the pain from the growth from which she was suffering would incapacitate her for her work. Another case, recurrent after operation, remains well after an equal interval of time. A fifth is still under treatment, the growth and the infected glands having much diminished in size.

Microscopical examination was not possible in all of these cases although it was made in the only two in which it was possible. This statement leads to the indication of another difficulty in establishing a medical treatment—namely, the want of microscopical examination. A mere clinical diagnosis, although such can be made with very considerable accuracy in the majority of cases in which sight and touch are available, is not held to be worth anything by the advocates of surgical procedure.

Now it must not be inferred that a claim to any finality in treatment is advanced, but a claim is made that the treatment advocated possesses a sound basis, and that the drugs which Dr. Morgan has made for the first time, such as the coumarate of sodium and tylmarin, are capable of exercising a very beneficial effect, even in cases of the worst possible type. As has previously been indicated, the stock-in-trade of the physician, so far as cancer is concerned, is composed chiefly of cases advanced in the disease, cases which have been treated with the knife, with the various light treatments, or with electricity, the class of case which I had never succeeded in alleviating until the time came when I founded for myself a new basis of treatment. The pleasure derived from giving alleviation of any substantial kind to such cases has been very considerable, and the disappointment of inability to proceed faster very great. A consideration of the facts obtained from the treatment of a considerable number of patients in the later stages of the disease leads me, however, to the belief that the advance made is great, although at the present time it is impossible to assert that all cases of cancer can be cured by medicinal treatment.

The term "cancer" connotes a disease which is caused by a cellular degeneration—the cells thus degenerated possessing the power of self-multiplication. As cellular multiplication increases, various troubles to the human frame result. The simplest form of trouble is injury by pressure of the growth upon adjacent organs, by interference with the lumen of natural passages, or by destruction of the organ invaded. The next simplest trouble is the local death of the tissues invaded, with the resultant absorption of the products of decomposition into the economy. A much more complex phenomenon is the spread of the disease from the seat of origin and the infection of other organs or structures. Still more complex is the condition known as "the cancerous

Remarks

ON

PERITONITIS AND ITS TREATMENT.

Founded on an Address delivered to the Trowbridge Division of the British Medical Association

BY JAMES BERRY, B.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO THE ROYAL FREE HOSPITAL.

"THE treatment of peritonitis has always been a fruitful topic of discussion and dissension and will probably remain so, as the final chapter on this subject has not yet been written."[1] Such, gentlemen, were the opening words of an American professor of surgery when giving an address on the treatment of peritonitis. They are unfortunately as true to-day as they were when they were spoken just a year ago by Dr. John Gibbon of Philadelphia. I make no excuse, therefore, for reproducing them and for making them serve as the text of my discourse to you to-day.

In the whole domain of medicine and surgery there is scarcely any disease so serious, so different in its clinical manifestations, so dangerous when wrongly treated, and yet so difficult to treat according to fixed rules. Peritonitis may be a mere local inflammation of comparatively little importance which quickly subsides under simple medical treatment or no treatment at all. More often it is a much more serious affection demanding prompt and careful medical or surgical treatment. Only too often does it come before our notice in the form or at a stage when neither physician nor surgeon can do much, if anything, for its relief. Acute peritonitis, subacute peritonitis, chronic peritonitis, general peritonitis, local peritonitis are all mere degrees of the same process, and yet how different as a rule is the treatment required for each. Not only so, but a form of treatment which is to be strongly recommended at one stage or in one form of peritonitis may be most harmful and disastrous in its results if employed at another, and perhaps not very far removed, stage or form of the same disease. But underlying our treatment of all forms of peritonitis there are certain broad principles that should guide us in our endeavour to select the best possible means of treatment in any individual case.

It will be my intention this afternoon to discuss some of these principles and to endeavour to apply them to the different forms of peritonitis which we are in practice called upon to treat. The subject of peritonitis is, however, such a vast one that I must ask you to allow me to limit myself and to deal only with acute peritonitis. With the various kinds of chronic peritonitis and with the minor and slighter forms of local peritonitis I am not especially concerned to-day. And you will not be surprised if as a surgeon I dwell more upon the operative than upon the non-operative forms of treatment. Not that I wish it to be thought that a surgeon always necessarily treats peritonitis by operation. On the contrary, I believe that there are many cases of acute peritonitis that for one reason or another are best treated without operation. It is the duty of a right-minded surgeon to be ready to operate in any case in which it seems to him best for the patient that he should operate. But it is equally his bounden duty to abstain from operating if in the case before him he thinks that operation will do harm rather than good.

Peritonitis—inflammation of the peritoneum—what is it? Why is it so dangerous, so much more dangerous than inflammation, say, of a muscle, or lymphatic gland, or even of a joint? The very term peritonitis is a misleading one It is not the mere inflammation of the peritoneum that is dangerous. This inflammation is in itself often exceedingly beneficial and protective. But peritonitis is dangerous in proportion as it is associated with *absorption* from the peritoneal cavity. It is the absorption of toxins from the peritoneal cavity, not the inflammation of the peritoneum, that is dangerous. The peritoneal cavity is, as we all know, a vast lymphatic space from which absorption of toxins readily takes place.

Let us consider for a moment what we mean by peritonitis. It is the inflammation of the peritoneum produced by the presence of bacteria. These may in some cases have come from the blood-stream, as when peritonitis occurs, as it occasionally does, in the course of an acute septic lesion of some other part of the body. Some of the cases of pneumococcic peritonitis secondary to pneumonia may perhaps be taken as an illustration. The bacteria may be introduced directly from without, as in the case of an accidental septic wound of the peritoneum or in the course of an operation performed without due attention to surgical cleanliness. But in the great majority of cases the bacteria are introduced into the peritoneal cavity from within by passing through the wall of one of the hollow abdominal viscera, the appendix, the intestine, the stomach, gall-bladder, Fallopian tube, &c. Not uncommonly the poisonous contents of the viscera are introduced through a visible opening in the wall of the viscus. Such is the case in the so-called perforative peritonitis. Perforation of a gastric ulcer, of an ulcer of the intestine, of the gall-bladder, are familiar illustrations of which we must all have seen many examples.

In appendicitis the amount of septic matter that suddenly escapes into the peritoneal cavity is generally quite small and often there is no visible opening in the appendix. Even if there is a definite visible opening the amount of septic matter that escapes is often small—perhaps only a drop or two, for example. The perforation of an appendix is usually preceded by adhesive inflammation of the lumen of that organ, which is apt to shut off the cavity of the appendix from that of the cæcum, so that all that escapes is what was in the appendix at the time of operation. This I have been able to demonstrate time after time in the post-mortem room when as surgical registrar I had abundant opportunities of doing post-mortem examinations on cases of appendicitis. By far the most serious and dangerous forms of peritonitis produced by appendicitis are those in which the perforated appendix has previously been distended and filled with a considerable quantity of foul septic fluid and those in which it is not the appendix itself that suddenly ruptures but an abscess that has slowly and quietly formed outside the appendix and which ruptures secondarily through its wall. These are the two conditions that are commonly found in cases to which the term fulminating appendicitis is applied. I am aware that this term is often applied, I think erroneously, to any case of acute appendicitis which happens to be rather more severe than usual. In the great majority of cases of acute appendicitis, then, the amount of poison that escapes is small. It is not more than the peritoneum itself can deal with. Most cases of acute or subacute appendicitis, therefore, even if not treated by operation, recover spontaneously, as all of us know who are old enough to remember the days when appendicitis was never treated by immediate operation.

But now let us take the case of a perforation of a large hollow viscus like the stomach or the cæcum. Here a perforation is rarely preceded by adhesive inflammation. The perforation occurs suddenly and is immediately followed by the pouring out into the peritoneal cavity of a vast quantity, often many ounces, of septic material. If the stomach perforated during digestion the quantity poured out is very great. If it happens that the stomach be empty at the time then the amount poured out, although usually considerable, is much less than during digestion, and these are the cases of perforated gastric ulcer in which symptoms are less severe and pronounced. It is in the case of sudden perforation of distended intestine, however, that we see the most violent and profuse invasion of the peritoneal cavity by a large quantity of horribly poisonous fluid material. Everybody here must have seen at one time or another one of these distressing cases of chronic obstruction of the large intestine which has been allowed to progress without relief by operation. A middle-aged or elderly patient gets obstruction of the bowels; he becomes distended, constipation persists, days, even weeks, elapse without relief. He has had little pain, very likely he is walking about, he probably vomits only occasionally, but the tension of his abdomen continually increases. Then suddenly he is seized with violent abdominal pain, he becomes collapsed, and in a few hours he is dead. The cæcum has suddenly perforated. At the post-mortem examination many ounces, perhaps half a pint or more, of thin liquid fæces is found spread out all over the peritoneum. The man has died from acute septic poisoning, the poison having been rapidly absorbed from the previously healthy and non-adherent peritoneum.

A similar train of symptoms is seen when a large intra-peritoneal abscess bursts secondarily into that part of the warmed to about 38° to 39°, and was shaken vigorously with air for about two minutes. At the end of this time its temperature had fallen to about 36·5°. It was warmed up a second time and the shaking repeated, and was then kept in a water bath at 37° for about half an hour in the case of the cod-liver oil and an hour in the case of the olive oil, these being the times required for all the bubbles of air to rise to the surface. The gaseous content of a weighed amount of the oil was then determined as before. The results obtained are given in the tables. They represent the volumes of gas, reduced to 0° and 760 millimetres, contained in 100 cubic centimetres of the oil at the temperature recorded, when saturated with air at a pressure of 760 millimetres. To calculate these values, it was assumed that the specific gravity of olive oil at 15° is 0·917, and at 37° 0·902.[3] The specific gravity of cod-liver oil, compared with that of water at 15°, was found by direct experiment to be 0·928 at 15°, and 0·914 at 37°.

---

100 c.c. of cod-liver oil contain—

	At 15° C.			Mean.	At 37° C.			Mean.
	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.	c.c.
Oxygen ...	2·34	2·31	2·22	2·29	2·21	2·22	2·22	2·22
Nitrogen ...	4·95	5·15	5·07	5·06	5·05	5·10	5·03	5·08
CO_2	0·19	0·25	0·19	0·21	0·18	0·24	0·20	0·21

Considering only the mean values, we see that in the case of each oil the solubility at 37° is within the limits of experimental error the same as its solubility at 15° C. A similar constancy was found by Bunsen for the solubility of oxygen in alcohol at temperatures from 0° to 24°, though Timofjew[4] has since found that the solubility does slightly diminish with the temperature. In any case the diminution is small (6·8 per cent. diminution for oxygen and 5·2 per cent. diminution for nitrogen between 0° and 24°) and if it exists at all in the case of these oils it must be smaller still. A simple proof of the slight effect of temperature on solubility is obtained by saturating the oil at room temperature and heating it gradually in a water bath. Not a trace of gas is observed to come off if the temperature be kept at 97°, but at 100° it bubbles off in very small quantities.

The observations on lard were carried out at one temperature only. Lard melts at from 36° to 48° and solidifies at from 27° to 30°, but if melted and shaken with air at 37° it is too viscid to allow the air bubbles to rise to the surface in a reasonable time. Hence the solubility was determined at 45°. The lard was heated to about 48° and then shaken violently for a minute with air, its temperature at the end of this time having fallen slightly below 45°. The process was repeated, and after keeping the lard in a water bath at 45° for about 35 minutes the gases were boiled off in the usual way. They came off quite as readily as from the olive and cod-liver oils. The data obtained are given in the table, they being calculated on the supposition that the specific gravity of lard at 45°, as compared with water at 15°, is 0·895.[5] If the mean values be compared with the mean values for the other fats it will be seen that the solubility of oxygen is practically constant throughout. That of nitrogen varies slightly, it being 5·23 cubic centimetres for olive oil (an average of the values at 15° and at 37°), 5·11 cubic centimetres for lard, and 5·07 cubic centimetres for cod-liver oil. Still these differences are almost within the limits of experimental error. In the case of the lard it is possible that the two minutes' shaking with air was not quite sufficient for complete saturation, but more thorough shaking was not possible as it brought down a slight precipitate which prevented the rapid clearing of the air bubbles.

100 c.c. of lard at 45° C. contain—				Mean.
	c.c.	c.c.	c.c.	c.c.
Oxygen	2·23	2·40	2·35	2·33
Nitrogen	5·05	5·09	5·18	5·11
CO_2	0·12	0·12	0·15	0·13

In that fats of such very different composition as the three experimented with dissolve practically the same amounts of oxygen and nitrogen we are fully justified in assuming that human fat would behave similarly. From the physical and chemical constants collected in the accompanying table[6] we see that the melting point of human fat lies between those of cod-liver oil and lard, whilst its iodine value is 61·5 per cent., or about the same as that of lard. In that cod-liver oil has an iodine value of about 145 per cent., and olive oil one of about 83 per cent., it follows that the proportion of unsaturated acids present in a fat has little or no influence upon its solvent powers for oxygen and nitrogen.

—	Cod-liver oil.	Olive oil.	Lard.	Human fat.
Solidifying point ...	0° to −10°	−6° (?)	27° to 30°	15°
Melting point ...	—	—	36° to 48°	17·5°

Iodine value	123 to 168%	79 to 88%	50 to 70%	61·5%

From the absorption coefficients for oxygen and nitrogen given by Bohr and Bock,[7] it is calculated that 100 cubic centimetres of water saturated with air at 15° absorb 0·733 cubic centimetre of oxygen and 1·411 cubic centimetres of nitrogen. Taking a mean of all the values obtained with cod-liver oil and olive oil at 15°, the solubility of oxygen is found to be 3·1 times greater than in water and of nitrogen 3·7 times greater. At 37° Bohr and Bock's values show that 100 cubic centimetres of water absorb 0·507 cubic centimetre of oxygen and 0·975 cubic centimetre of nitrogen. Taking a mean of all the values obtained with cod-liver oil and olive oil at 37° and with lard at 45° (for doubtless the solubility at this temperature is practically the same as at 37°), the solubility of oxygen is found to be 4·5 times greater than in water and that of nitrogen 5·3 times greater. It has been found by Bohr[8] that blood plasma dissolves 2·5 per cent. less nitrogen than an equal volume of water, whilst blood dissolves slightly less still; hence we may conclude that at body temperature the fat of mammals dissolves at least five times as much nitrogen as water or as blood and blood plasma.

The solubility of oxygen in fats, though apparently less than that of nitrogen, may in reality be as great. It is well known that oils are able to absorb and combine with oxygen, and the rate of this absorption is by no means inconsiderable. For instance, a sample of olive oil was saturated with air at 15° and was kept for 23 hours at 18° in a stoppered bottle filled to the brim. It then yielded only 0·49 cubic centimetre of oxygen per 100 cubic centimetres, whilst some of the sample from which the air was boiled off an hour after saturation yielded 2·40 cubic centimetres. Owing to its richness in unsaturated acids cod-liver oil absorbs oxygen more quickly still, and a sample saturated with air at 15° and kept 23 hours at 18° in a stoppered bottle gave only 0·05 cubic centimetre of oxygen per 100 cubic centimetres. Undoubtedly, therefore, there must have been some absorption of dissolved oxygen during the half to one and a half hours the air-saturated oils were kept before analysis.

It might be thought that the solubilities determined by the letting out of this fluid by operation leads to the effusion of a further amount of fresh serum and the destruction of more bacteria. Hence the beneficial effect of drainage of inflamed areas. The beneficial effects of draining away the fluid in chronic tuberculous peritonitis is thus explained. One other point I should like to allude to and that is the effect of a dose of toxin upon the opsonic power of the blood plasma. A dose of toxin of sufficient size produces at first a lowering of the opsonic index—that is, the patient enters into what is called the negative phase with regard to that particular bacillus. If, then, a further dose of toxin is immediately administered, as is necessarily done to a greater or less degree by the traumatism of an operation, then the negative phase may be still further increased even to the point of death. But after an interval of a few days, about three or four, the opsonic index is greatly raised to far above the normal and operations at this stage can be performed with very much greater safety.

The particular form of bacillus with which we most often have to deal in cases of perforative peritonitis is, of course, the colon bacillus, and it is to this form that my remarks more especially apply. There are, of course, various other kinds of bacilli that play their part in the production of peritonitis, but I do not propose to discuss them to-day. Much has been written of late about the virulence of the bacteria and its effect upon the production of peritonitis. Without wishing to detract from the value of observations upon the virulence of bacteria in particular cases, I would say that I think that of late undue stress has been laid upon the *quality* of the bacteria and too little stress upon the *quantity* of poison that is the cause of a perforative peritonitis. A tolerably extensive experience of peritonitis both in the post-mortem room and at the bedside, an experience extending over a period of more than five-and-twenty years, has convinced me that, other things being equal, it is upon the *quantity* of poison that is suddenly effused into the abdomen rather than upon the quality that the severity of the attack of peritonitis depends; and this is especially true of the peritonitis connected with appendicitis, that most common cause of peritonitis.

Now as to treatment. I have gone at some length into matters of pathology and symptoms because a correct knowledge of the state of affairs before us has a most important bearing upon our treatment. The first point then for us to decide is the diagnosis. The more early and the more exact the diagnosis the better shall we be able to treat an individual case. The next point is to give a prognosis. What is likely to be the natural course of the illness if left to itself. What is likely to be the effect of the various modes of treatment that we can offer. The nature of the perforation, if there be one, the quantity of poison effused, the character of the poison, and especially the *quantity*, all effect powerfully the prognosis in an individual case.

The condition of the patient when first seen and the severity of the symptoms are often enough to enable us to decide at once that the prognosis is extremely grave and perhaps that an immediate operation offers the best prospect of recovery. In peritonitis there is much truth in the saying that prevention is better than cure. We shall doubtless all be agreed that in a case of perforation of a gastric ulcer the sooner an operation is performed the better for the patient. In the case of sudden perforation of an appendix, or of an appendix abscess, the same course is *sometimes* the wisest one to adopt.

But it must be remembered in connexion with acute appendicitis that *it is only in a minority of cases that there is any actual or visible perforation*. Of 460 consecutive cases of acute appendicitis published by Ochsner, in 255, considerably more than half, there was no perforation. The case for immediate operation is then very different from that of perforation of a stomach. But a peritonitis due to the escape of a small quantity of poison may spread steadily and the patient gradually pass into a condition in which operation is attended with grave risk. Here then is a difficulty, which some surgeons attempt to solve by teaching that all cases of early appendicitis should be operated upon *if seen early*. There is much to be said, in favour of this view. But, practically, we surgeons do not see cases of acute appendicitis very often in this very early stage. And if one adopt the rule, also laid down by some surgeons, of operating upon all cases as soon as they are seen we should very often operate on patients at an unfavourable stage, at a stage when the mortality is admittedly high, at a stage when, in my opinion and that of many surgeons, it is usually best to defer operation, for a time at least. At this later stage much may already have been done by nature in a case of intra-peritoneal inflammation by shutting off and localising the poison. The risk of an operation at this somewhat later stage is that we may undo much of the good that has already been done.

It is absurd to pretend that operations, especially large operations, upon patients suffering from acute peritonitis do not carry with them much risk. What we have to consider is whether the risk of the operation with its necessary attendant evil is, or is not, more than counterbalanced by the good it is likely to do. The harm that a large operation may inflict is twofold: shock from manipulation and exposure of viscera and further absorption of septic matter by diffusion and absorption of poisons already more or less shut off by adhesions and omentum from the circulation. But, on the other hand, what good does an operation do? We can do two things by operation, and practically all operations for peritonitis do these two things only. Firstly, we can, by closing a perforation or removing a septic focus, prevent the further entrance of poison into the peritoneum. Secondly, we can to a limited extent, but to a limited extent only, remove the poison that is already in the peritoneal cavity. I think that most surgeons will agree that the removal of septic matter from the peritoneum by operation is never complete. We can remove a great deal; we can often remove so much that the peritoneum itself can deal with the little that is left. I have in past years seen the abdomen washed out in the most thorough manner with gallons of fluid, but the septic matter was not all removed and the patient, though operated upon in quite an early stage of peritonitis, has nevertheless died of sepsis. What we cannot do by operation is to remove from the blood the poison, bacteria or toxins, that have already entered it. But we can to a certain extent get rid of these poisons in the blood by other means—namely, by encouraging excretion of them through the kidneys and in other ways. And this is done mainly by the administration of fluid in one way or another.

Now for purposes of treatment I should like to divide all cases of peritonitis into four classes.

I. Those in which there is no perforation of any viscus and in which there is no collection of fluid in the peritoneal cavity. The early stage of a peritonitis supervening after an abdominal operation in which no hollow viscus has been opened may be taken as an example. The amount of poison in the peritoneal cavity is in such a case very small. In such cases free purgation by salines and the administration of large quantities of fluid either by the mouth or, better, by the rectum, or in severe cases by the subcutaneous tissue, or even into a vein, is, in my opinion, the best form of treatment. This treatment aims at eliminating by bowels and kidneys the toxins that have already entered the circulation and puts the peritoneum in the best condition for destroying the bacteria that remains. Opium should be avoided in such cases. If this treatment fails to arrest the course of the inflammation it may be desirable to drain the peritoneal cavity if there is any evidence that there is free fluid in the peritoneal cavity.

II. The second class is that in which we know, or strongly suspect, that there is a recent perforation of a hollow viscus, such as the stomach or intestine. Here an immediate operation should be performed with the object of closing the perforation and preventing further extravasation into the peritoneal cavity. When once the diagnosis has been made the sooner the operation can be done the better. If it can be done before symptoms of peritonitis have become well marked so much the better. A perforated gastric or duodenal ulcer affords the best example of this type of case. A minority of cases of acute appendicitis, the fulminating group, come into the same class. The very hopeless cases of perforation of a distended cæcum may also be treated in this way, but it is very rarely, if ever, that operation can in these cases be done soon enough to be of any use.

In the cases of this class it is prevention of peritonitis rather than the cure of peritonitis that is aimed at. With regard to the best method of dealing with the material that has already been effused into the peritoneal cavity much difference of opinion prevails. Some advocate thorough flushing of the whole peritoneal cavity, others prefer local sponging, others again trust mainly to drainage. In the less severe cases operated upon early it is sometimes permissible to close the abdomen without drainage. For my own part, after a tolerably extensive experience of all these incomplete abortion one sees; and that, undoubtedly, many of them are self-induced.

Clapton Park, N.E.

ERRATUM.—In Dr. Alexander Morison's paper on the Nature and Management of Hypertrophy of the Heart, published in THE LANCET of August 24th, p. 506, column 2, *line 8, the words "diminishing hypertrophy"* should be "dilatated hypertrophy," and on p. 508, column 1, line 2, the word "rib-cartilages" should read "ribs and cartilages."

EAST LONDON CHILDREN'S HOSPITAL, SHADWELL, E.

A CASE OF DOUBLE DEPRESSED FRACTURE OF THE SKULL AND PNEUMOTHORAX.

(Under the care of Mr. W. H. BOWEN.)

FOR the notes of the case we are indebted to Dr. W. Norman May, resident medical officer.

A boy, aged 15 years, was admitted to hospital on August 2nd at 7.30 A.M., the history being that about half an hour previously he had fallen off his bicycle and that the wheels of a van had passed over his head. He was unconscious and cyanosed with feeble running pulse and stertorous breathing. Fractures could be felt in both parietal regions, the one on the left side being more anteriorly placed than that on the right and not quite so near the vault of the skull. There was paralysis of the right arm and the right leg and the pupils were unequal. Some bruising was noticed, as if made by a wheel, over the first, second, and third ribs on both sides below the clavicles.

As the boy's condition was extremely serious he was immediately taken to the theatre and operated on by the resident medical officer. An incision over the left parietal region showed a depressed fracture over the motor area, the depressed fragment being triangular in shape, 2½ inches in length, and 1 inch in width at its base, which was formed by the fronto-parietal suture, the fracture extending through the centre of the parietal bone. The fragment was depressed beneath the surrounding bone, which overlapped it at its edges, and it was not until the fragment had been trephined at its border that it could be elevated and removed. The dura mater underneath appeared to be uninjured, while the fracture could be felt to continue down into the left temporal region but was not depressed there. An incision over the right parietal region showed a depressed fracture, gutter- shaped and running in a longitudinal direction, rather above the centre of the parietal bone. This was also trephined and the bone elevated, but there was no fragment broken off. The fracture could be felt to extend down into the right mastoid region but with no depression. The incisions were sewn up with salmon-gut sutures and the patient was sent back to bed, the operation having taken about 25 minutes. The patient's breathing became much better after the anæs- fragment on the left side had been elevated and an thetic became necessary to complete the operation. A few hours later the patient recognised his friends and spoke to them, also asking for things he wanted, while the movements in the right arm and leg returned, although the right arm was still weak. His breathing was very rapid and the alæ nasi were noticed to be working, so his chest was examined again. On the right side there was a tympanitic note on percussion and the breathing was most markedly bronchial in character; the heart was displaced to the left and there was some emphysema at the root of the neck. An exploring syringe put into the right side of the chest confirmed the diagnosis of pneumothorax. The patient's breathing gradually became worse and he died at 9.30 A.M. the following morning, 26 hours after the accident, apparently entirely from his lung trouble, as he was quite conscious up to the end and there were no paralyses of any kind.

Necropsy.—A post-mortem examination made on the following day showed the trephine holes as made at the operation, with the dura mater intact and normal and the brain uninjured and with no trace of hæmorrhage, laceration, or contusion. The fracture on the left side extended down into the temporal fossa and involved the roof of the orbit to a very slight extent, while on the right side the fracture just reached down to the mastoid process, but there was no effusion of blood or depression of bone on either side. The right lung was collapsed and on opening up the trachea it was found that the right bronchus was torn completely across immediately below the bifurcation of the trachea, the torn ends being separated for half an inch. The rest of the structures at the root of the lung were uninjured; there was no blood in the pleural cavity and the ribs, clavicles, and pleuræ were quite intact.

Remarks by DR. MAY.—The occurrence of these two interesting lesions in one case—namely, an apparently recoverable double depressed fracture of the skull and a pneumothorax caused by complete rupture of the bronchus without any injury to the ribs—seems to render this case worth recording. For permission to publish it I am indebted to Mr. Bowen, under whose care the patient was.

Reviews and Notices of Books.

Epilepsy: A Study of the Idiopathic Disease. By WILLIAM ALDREN TURNER, M.D. Edin., F.R.C.P. Lond., Physician to Out-patients at the National Hospital for the Paralysed and Epileptic, Queen's-square, and King's College Hospital, London; Visiting Physician to the Colony for Epileptics, Chalfont St. Peter, &c. London: Macmillan and Co., Limited. 1907. Pp. 272. Price 10s. net.

As a special monograph on the subject of idiopathic epilepsy Dr. Aldren Turner's book leaves little to be desired. It is a careful study of the disease chiefly from the clinical standpoint, with some interesting and important observations on its pathology contributed by Dr. John Turner of the Essex County Asylum. At the outset Dr. Aldren Turner premises that he regards epilepsy as an organic disease of the brain and that the morbid conditions which produce the convulsions eventually progress to those underlying the permanent dementia. After an introductory chapter he devotes two chapters to the etiology of the disease, in which he gives an exhaustive critical study of his own statistics and those of other authorities in regard to the causation of epilepsy. As a result he concludes that the proportion of epileptics in the general population *is* about 2 per 1000, that there is a slight preponderance in the male sex, and that the most important predisposing causes are ancestral epilepsy and neuropathic predisposition, which are found in about 50 per cent. of the cases.

In regard to the age incidence he finds that at least three fourths of the cases arise under the age of 21 years and that the greatest number of cases commencing in any one year is to be *found* in the first year of life. The so-called stigmata of degeneration are found to be very commonly present in the subjects of epilepsy, especially in those cases commencing early in life. A careful analysis is given of the supposed determining causes of the *convulsions* such as the effect of various physiological, psychical, and patho- logical processes or their development, among them sleep, fright, trauma, and alcoholism. The general con- clusion arrived at is that in those who have inherited the epileptic tendency a *convulsive* habit may be established either in the course of natural development or as a *result* of certain occasional or accidental *causes*. Two *chapters* follow on the clinical features of epileptic *fits* and in these Dr. Aldren Turner largely follows the *descriptions* of Herpin, whose law he enunciates as *follows*: "That although mentioned, but they are counted among the deaths in order to include the entire mortality of all cases treated."

Many cases of acute abdominal inflammation are first seen by the surgeon when the distension and acute symptoms have already begun to subside and in many of these operation may at once be undertaken with advantage. There is often danger in waiting too long and allowing pus to disseminate, although the danger is not usually so great as that of operating too soon in these cases. The treatment of localised intraperitoneal suppuration scarcely comes within my province to-day. But I might just say that one or other of two classes of operation should be done according to the stage which the suppuration has reached and the situation of the abscess. Either the abdomen should be freely opened, the region of the abscess carefully walled off with gauze *before* the abscess is opened; or else, if the abscess is in contact with the abdominal wall over a considerable area (and palpation affords the best means of determining this) a simple incision into the abscess within the area of adhesions is sufficient. The danger of the first course is that the abscess may unwittingly be opened before the gauze packing has been placed in position; the peritoneal cavity then becomes suddenly flooded with a large quantity of septic material and very grave risk is incurred. This is a not uncommon cause of death in unskilful hands. Frequently this method of opening the abscess is the only one that is available, as in cases where the pus is not in contact with the abdominal wall in such a manner that it can be opened by simple incision. The danger of the second course is that in the simple incision of an abscess, such as that of the appendix, the area of limiting adhesions may be transgressed and the non-adherent and consequently absorbing peritoneal cavity opened up and flooded with septic pus in the manner just described with equally disastrous result. I show you here six diagrams which I published some years ago in THE LANCET.[3] They are of cases of appendix abscess which came under my notice in the post-mortem room when I was surgical registrar. Each shows the area over which there were adhesions between the abscess and the abdominal wall. I have now added to each the incision that was actually made by the operator and it will be seen that in all the cases the non-adherent peritoneum was opened with fatal result.

A very excellent method of opening localised collections of pus, and one that I frequently employ, is that of making an incision through the posterior fornix of the vagina in women or through the rectum in males. But in order to do this with safety there must be a sufficiently large collection of pus, and ordinary care must be taken not to wound other important anatomical structures. It is frequently far safer to drain by the vagina than to do so through a deep incision through the anterior abdominal wall. The one thing that must not be done in the opening of an intra-abdominal abscess is to cut into it without due regard to the protection of the non-adherent peritoneal cavity. Either the general cavity must be carefully protected by gauze packing or advantage must be taken of adhesions already present if disaster is to be avoided.

IV. I come now to the fourth class of cases, those in which there is a general diffuse peritonitis with general distension of the whole abdomen and purulent fluid diffused over a large portion or the whole of the abdomen. I would here point out that diffusion of septic matter over the *whole* abdomen is not so common as is often thought. The post-mortem experience that I gained during the years when I was surgical registrar to a large London hospital taught me that many cases which clinically seemed to be cases of general peritonitis involving the whole peritoneal cavity were often found post mortem to be really cases in which the peritonitis was localised to a portion only of the abdomen, perhaps two-thirds or three-fourths only. Generally some small portion of the peritoneal cavity was not involved.

Of the symptoms of this form of peritonitis I need not say anything as they are sufficiently well known to all of us. With regard to the appropriate treatment there is much difference of opinion. Dr. Gibbon[4] of Philadelphia in the paper I have before alluded to says that "surgeons in their attitude towards a generalised peritonitis may be put into three classes. Those who do nothing in the way of operative interference but simply keep the patient quiet and the stomach empty until the inflammatory process and exudates have become localised, and if the patient lives until this has taken place they then operate. ...... The next class is made up of those who believe in immediate and radical surgical intervention, consisting in freely opening the peritoneal cavity, breaking up all adhesions, opening all pockets and thoroughly irrigating the entire peritoneum. The third and more recent class believe that the abdomen should be immediately opened, the cause of the inflammation sought for and removed, and the abdomen thoroughly drained with the least possible disturbance of viscera." Dr. Gibbon goes on to say that it has always seemed to him that "the failure to get the good results reported from certain lines of treatment is because we do not carry them out as specifically as is recommended by their advocates: in other words, we, inclining possibly to the operative treatment in employing the Ochsner method, do it half-heartedly without expecting a good result, whereas Ochsner carries it out to the letter and expects good results. We have all seen a very incomplete and injurious irrigation of an abdomen done in cases of general peritonitis. Such treatment, unless it is carried out thoroughly and every part of the abdomen irrigated, can be of little benefit if it is not definitely harmful, and this accounts for the difference in results obtained at the hands of those who are enthusiastic over irrigation and of those who do not look upon it with the same confidence."

The Murphy method as described by Gibbon "consists in making a small opening in the abdomen, closing the perforation or removing the appendix as the case may be, the introduction of a large drainage-tube into the pelvis, placing the patient in a sitting posture of from 35 to 45 degrees, and the administration of a quart of salt solution every two hours per rectum." Gibbon quotes Murphy's words as follows and they seem to me to be of the greatest importance: "It is a fatal mistake," says Murphy, "to mop, wash, or handle the intestines or peritoneum. Then, too, the simple opening of the abdomen relieves the pressure under which the pus rests, and we know all that is necessary to stop absorption from a pus accumulation in any part of the body is to open the cavity and relieve the pressure. It is injurious and even dangerous to milk or even handle an acute abscess; it is doubly so to handle an infected peritoneum, but the pressure should be relieved by opening it, allowing it to drain, and exposing the anaerobic flora to the air." Gibbon describes eight cases of his own in which he had adopted the Murphy method and he had five recoveries and three deaths. He expresses himself as a warm convert to the Murphy method. He further states that he had heard Murphy say in October, 1905, "that he had had 29 cases of diffuse or general peritonitis in which he had employed his method with but a single death, this one occurring from pneumonia on the sixth day."

Like most surgeons, I suppose, I have tried all three methods at different times, and I am inclined to the belief that of the three the Ochsner method is the one that is most suitable for the great majority of cases of diffuse peritonitis. For the very worst class of case, in which no delay is possible, and they are, I think, few in number, the Murphy method is undoubtedly good. I entirely agree with those who condemn the very large operations which are so often performed in this country. The mortality of these operations, so far as I have seen and so far as I can judge from those who have published detailed statistics of their cases, has been literally terrific.

I think I notice at the present day a tendency amongst surgeons of large experience to abstain more and more from these very large operations. We are beginning, I think, to realise more and more fully that many very bad and apparently hopeless cases of general peritonitis will recover if the surgeon will abstain from doing any large operation. In this connexion I should like to refer to an admirable paper by Mr. J. Rutherford Morison, a well-known advocate of extensive operation in early cases of appendicitis. He gives details of a large number of cases treated with excellent results. But speaking of general peritonitis he says: "General peritonitis of more than 24 hours' duration is not likely to be benefited by operation, for the favourable chance has been lost; indeed, an operation not seldom hastens the end and may be the cause of death," and he goes on to say, "it is not without surprise that I have observed recovery in such cases without operation." In this paper he gives details of 15 cases of general septic peritonitis. Ten of them were treated by operation, with eight deaths, while five of them were treated without operation, with only one death! The numbers are small, but I think significant, the treatment of some of these, notably pneumonia, pulmonary tuberculosis, and asthma, is given in some detail, while various measures and drugs are recommended. The genito-urinary system and the osseous, muscular, and articular organs are considered and the diseases affecting them are described, and then diagnosis and treatment are outlined. One chapter is devoted to the infectious and contagious fevers; the means of disinfection are well described and the general management and treatment of each disease are given. Another chapter deals with the diseases due to faulty metabolism, to abnormal conditions of the ductless glands, and to variations in internal secretions. In the section devoted to diseases of the nervous system short descriptions of the various diseases are given rather than a consideration of their diagnosis, while their treatment is very briefly described. The concluding chapters are given over to dermatological, otic, and ophthalmic memoranda, and to certain miscellaneous conditions such as anæsthesia and various intoxications and to the methods of keeping case records.

---

[3] THE LANCET, Dec. 30th, 1899, p. 1858.

[4] The Treatment of Diffuse and General Peritonitis with Special Reference to the Murphy Method, New York Medical Journal, April 7th, 1906, p. 706.

While Dr. Caillé's book is comprehensive in its scope and contains a great deal of information it is on the whole too ambitious in its aims. It would be improved by omitting the general descriptions of the diseases considered, which are of necessity less complete than those in the ordinary text-books of medicine, and by devoting the space to more detail regarding the diagnosis of those diseases from conditions with which they may be confused. Moreover, the descriptions given of treatment are curiously uneven, some being given in detail with actual prescriptions, and others in mere outline or in vague general terms. The book is copiously illustrated and well produced.

On Treatment. By HARRY CAMPBELL, M.D., B.S. Lond., F.R.C.P. Lond., Physician to the North-West London Hospital and to the Hospital for Diseases of the Nervous System, Welbeck-street. London: Baillière, Tindall, and Cox. 1907. Pp. 421. Price 5s.

IN his preface the author states that in this work he "treats of certain questions of therapeutics from his individual point of view." It is quite refreshing to find such original ideas on a subject so widely written upon as therapeutics. There is a quality about Dr. Campbell's writings that is very attractive and we have perused this volume with much pleasure. The title, perhaps, is a little misleading, for the book does not deal with the actions of drugs in the treatment of various diseases, but is founded on broader and more general lines on which, however, much of a practitioner's success in practice will depend. To the student preparing for examination the work will not appeal, but the young practitioner will find it of considerable value when commencing his private medical work, whilst those who have been long in the routine of their profession will derive many valuable hints as to the general management of their patients.

The earlier chapters of the book on the physician's physical and mental personality contain much that is interesting and instructive, perhaps it may almost be added entertaining. According to the present state of medical education students are trained more for examination purposes than for the actual practice of their profession. After the qualifying examinations are passed much will have to be learned before the knowledge gained in the schools can be with full advantage made use of in the daily routine of medical work. It is on such matters that Dr. Campbell mainly dwells. The "entire mental equipment of the physician" is considered in a most excellent manner. He points out that the physician needs to be versed in many kinds of knowledge. Not only must he be well up in his professional work but he must be a man of the world in the sense that he must be in touch with the life around him, not wrapped up in learned theories and technicalities. Dr. Campbell further remarks that "the physician who is merely learned in the learning of the schools, who refuses to come out of his professional aloofness and study man in his wider relations, is indeed hardly worthy of the name and is sure to prove a failure. The most distinguished career at college will avail him nothing; he is bound to be outstripped by the men who, though greatly his inferiors in learning, have been spending the time that he has devoted to books and the more purely scientific aspect of his profession in acquiring a greater knowledge of mankind and things in general." There is much truth in these observations, and although an extreme course might be taken in either direction, yet an intimate knowledge of human nature apart from scientific considerations will greatly aid the practitioner in the treatment of his patients.

Dr. Campbell's remarks on psycho-therapeutics, clothing, muscular exercise, and diet contain numerous trustworthy hints and suggestions as to the general course of life which individuals should follow in health and in disease. He draws attention to the many evils attaching to a sedentary life, amongst which fixity of the chest and atrophy of the abdominal muscles are not the least. Under normal conditions, and especially in the upright position, the muscles of the abdomen exert considerable pressure upon the abdominal contents. Such pressure, as the author points out, serves two useful purposes: it helps to keep the abdominal viscera in their right position and to prevent an undue accumulation of blood in the splanchnic veins. Hence the advantage in certain digestive disorders of regulated exercises which tend so develop the weakened muscles. In his remarks on diet Dr. Campbell enunciates "certain dietetic truths" which are of considerable importance in insuring good health. He points out that man is an omnivorous being; that it is his vegetable rather than his animal food that requires mastication; that starch can be, and ought to be, by thorough mastication, largely digested in the mouth; "that an untold number of evils result from the prevailing system of pap-feeding"; that often much good can be obtained by reducing the carbonaceous constituents of the food (notably the saccharides) or the proteins; that a long train of ills follows from over-eating; and that frequently it is much more useful to reduce the total quantity of food than to prohibit any particular item in it. These and other statements contain information that will be found useful in giving directions as to conditions brought about by administration of a faulty diet. Students learn but little of such matters during their hospital days, and it is to be regretted that more attention is not given to tuition in a subject that has far reaching importance.

In conclusion, we may add that the whole book is pervaded with an interest which is not to be found in ordinary text-books, and we believe that it will obtain a popularity which it thoroughly deserves.

Manuel de Gynécologie Pratique. By Dr. J. BAROZZI, Ancien Interne des Hôpitaux de Paris. With Preface by L. G. RICHELOT, Professor agrégé, Membre de l'Académie de Médecine. With 153 figures. Paris: Vigot Frères. 1907. Price 10 francs.

THIS work is not in any way to be considered as a complete treatise on gynæcology; it is merely intended to be a manual or a vade-mecum. We must not therefore look for the completeness we would expect in a more ambitious book but we may expect to find special stress laid on those subjects which are but imperfectly treated in more extensive works. In writing this book the author has addressed himself rather to those students and practitioners who have not had the advantages of a prolonged clinical

TABLE GIVING DETAILS OF 11 CASES OF ACUTE YELLOW ATROPHY OF THE LIVER.

No.	Author.	Sex.	Years of age.	Predisposition.	Anæsthetic.	Operation performed.	Onset of Icterus	Symptoms.	Result.	Necropsy.
1	Bastianelli.	?	?	?	Chloroform.	?	?	Icterus, vomiting, delirium.	Died between second and tenth day.	Fatty degeneration of heart; nephritis; punctiform hæmorrhages.
2	"	?	?	?	"	?	?	" "	"	" "
3	"	?	?	?	"	?	?	" "	"	" "
4	Bandler.	M.	42	Alcohol.	Chloroform, 80 grammes	Herniotomy, with resection of adherent omentum.	1 to 2 days.	Icterus, delirium, coma; temperature 40° C.	Died fourth day.	Acute yellow atrophy of liver; icterus universalis; multiple hæmorrhage; nephritis.
5	Stocker.	F.	?	?	?	Ovarian cyst with torsion and necrosis of pedicle.	?	?	Died.	Acute yellow atrophy.
6	Erlach (reported by Bandler).	F.	?	Catarrhal icterus.	Billroth mixture.	Extirpation of uterus with morcellement of fibroma.	?	Icterus, delirium.	Died.	Atrophica hepatis acutis rubra et flava.
7	Mintz.	M.	40	Alcohol.	?	Appendicitis with infection.	1 day.	Icterus, hæmatemesis, convulsions, fever.	Died sixth day.	Fatty degeneration of heart; parenchymatous nephritis; acute yellow atrophy of liver; erosions in duodenum and stomach.
8	Marten.	F.	34	Insanity: indigestion.	70 c.c. chloroform, 40 minutes.	Extraction of 13 teeth; suppurating necrosis of jaw.	1 day.	Icterus, vomiting, albumin casts in urine, delirium, yelling, coma.	Died fifth day.	Fatty degeneration of heart and kidneys; acute fatty degeneration of liver.
9	Cohn.	F.	21	Alcohol.	Chloroform.	Salpingo-oophorectomy for pus tubes.	2 days.	Icterus, fits of yelling, delirium, albuminuria.	Died fifth day.	Cloudy swelling of heart, liver, and kidneys; icteric meningitis.
10	Ballin.	M.	20	Lead.	"	Appendicectomy in inflammatory stage; adhesions.	2 days.	Icterus, delirium, bloody vomit, albuminuria, leucin and tyrosin in urine.	Recovery.	—
11	Campbell Horsfall	F.	28	None.	"	Intestinal obstruction due to adhesions.	1 day.	Icterus, convulsions, vomiting, coma.	Died fourth day.	Acute yellow atrophy of liver.

was quite healthy. On separating some adhesions a definite mass of about the size of a small orange could be felt on the left side of the abdomen. With great difficulty, owing to the many adhesions, the mass was brought into view and was found to consist of a loop of small intestine firmly constricted at its base by adhesions and tense from accumulated contents. The adhesions were divided and the mass immediately subsided. The intestinal wall had not suffered much damage and so was returned and the abdomen was closed in the usual way with the exception of a small wick of gauze for drainage. The patient stood the operation well and when seen the same night was comparatively comfortable with the exception of vomiting which was considered to be due to the anæsthetic. The vomiting continued the next day and the patient was very restless. Flatus had been passed freely and the temperature and pulse were normal. In the evening I noticed her conjunctivæ were icteric but I did not think it more than the ordinary simple jaundice sometimes occurring after an anæsthetic.

On the following morning the patient still continued very restless and the jaundice was now general. Vomiting continued, at first bilious but gradually becoming darker as though mixed with altered blood. The urine was bile stained. The wound was dressed and the gauze wick was removed, everything appearing satisfactory. There was no distension of the abdomen. As the vomiting continued the stomach was washed out and five grains of calomel, followed by one ounce of white mixture, were given by the mouth. Later there was a small action of the bowels and flatus passed freely. The jaundice gradually deepened, the patient became very drowsy, and the skin was dry and pungent, the face being a dusky red in comparison with the yellowishness of the rest of the body. There were convulsive movements of the limbs on both sides, followed by well-marked muscular rigidity. From this she gradually passed into a condition of coma vigil, was totally unconscious, had deep, stertorous breathing, and fixed, staring eyes with widely dilated pupils. The urine became diminished and was passed involuntarily. On percussing the liver the dulness anteriorly was markedly decreased. The vomiting became less as the patient's condition grew worse. The urine was examined for leucin and tyrosin crystals with a negative result, but albumin and bile pigments were present. A diagnosis of acute yellow atrophy was made. Venesection was at once performed and several pints of normal saline solution were injected into the median cephalic vein of the left side, but all to no purpose. The temperature gradually rose to 105° and death took place early the next morning.

I obtained permission from the relatives to make a partial post-mortem examination. I removed the liver after first ascertaining that there was no obstruction to the common duct. The liver was much reduced in size and its capsule was shrunken. The gall-bladder was filled with thick bile. A section of the liver showed areas of red softening, the surrounding parts being yellowish. The liver tissue was very friable. The ducts macroscopically were healthy. I reopened the operation wound and found everything healthy, there being no evidence of suppuration anywhere. A portion of the liver was sent to the pathological department of University College, Bristol, and was reported on as follows: "The specimen was very soft and friable. There is present a great degeneration of the liver substance, with deposition of pigment. The amount of newly formed fibrous tissue is small, thus indicating great acuteness of the disease. The appearances presented are those usually seen in acute yellow atrophy."

The notes of the above case are of more than usual interest, partly because of the extreme rarity of the disease and more so because of the fact that there are now on record 11 cases following an operation in which an anæsthetic has been given, and as such should be reckoned as a possible complication following operation. Modern text-books nearly all omit to mention it.

On referring to the table it will be seen that in all but scientific work can be done even in a simple form which does not provide for accurate measurement. Among the additions which have been made to the present edition is a chapter on the staining of bacteria by Dr. Maurice Amsler. It is, as he states, written in as concise and simple a manner as possible and in the 12 pages devoted to the subject five stains, including Gram's iodine solution, and four culture media are mentioned. Within the limits of the space devoted to the subject its treatment is satisfactory, and the medical student as well as the general beginner in microscopy will find this chapter of value. There are one or two misprints in the book which do not call for detailed notice except to point out that on p. 140 the μ unit is made ten times too great. The "$\frac{1}{2500}$th" part of an inch should be $\frac{1}{25000}$th part. "The Marine Aquarium as a Field for Microscopical Research" and "The Microscope at the Sea-side" are sections of the book which will appeal to many, and the account of Mr. White's method for the crystallisation of hydroquinone will be welcomed by all who take an interest in polariscope objects. We remember Mr. White's demonstration with this substance at the Camera Club some years ago and the beautiful effects which he then produced with it. *Apropos* of the present controversy regarding alcohol, Mr. White's method of killing polyps with their tentacles expanded may be mentioned. Into the trough holding the expanded polyps he allows minute drops of whisky to trickle "and become so gradually diffused through the sea water that the polyps becoming accustomed to its blissful influence succumb to it and forget to draw in their tentacles." The book in its present form is a useful addition to the many elementary treatises on the microscope.

JOURNALS AND MAGAZINES.

The Scottish Medical and Surgical Journal.—An address entitled "The Physician as Naturalist," delivered by the late Sir William T. Gairdner, and published in the August number of this journal, bears no signs of age upon its face, but we find in a footnote that it is a reprint of a Presidential Address of 1888. In it stress is laid upon the value of a scientific training for the physician, a view with which it is impossible to disagree, though opinions may vary as to the extent to which, when something must go, it is wise to insist upon a knowledge of certain branches of natural science to the exclusion of general culture. Mr. Lewis Beesly writes on Excision of the Hip-joint and the After-treatment thereof, advocating a modification of Koenig's procedure, the remains of the upper end of the femur being moulded to fit into the acetabulum and kept in place by continued abduction.

The Medical Chronicle.—The principal article in the August number of this magazine is the first part of a thesis by Dr. Ernest Bosdin Leech on Occult Hæmorrhage in the Gastro-intestinal Tract. By this term, due to Boas, is meant the occurrence of any escape of blood too small to be distinguishable with the naked eye. A very complete account is given of the various methods devised for the recognition of traces of blood in the fæces. Incidentally it is mentioned that experiments seem to show that hæmoglobin is not well absorbed from the intestine, a point of interest in relation to the use of preparations of this substance for the treatment of anæmia. Dr. Judson S. Bury records two cases in which one disease appeared to have a beneficial effect upon another —a case of heart failure improved by an attack of cellulitis and one of muscular wasting and paresis improved by intercurrent small-pox.

The Edinburgh Medical Journal.—The August number of this journal opens with a most interesting paper by Dr. K. G. Lennander of Upsala on Abdominal Pain, in which the author maintains that the stomach and intestines, being supplied by the vagus and sympathetic nerves, have no sensation of touch, temperature, or pain. Pain he considers is due in all abdominal affections to implication of the parietal peritoneum or to traction on the mesentery. Professor H. Harvey Littlejohn and Mr. T. W. Drinkwater report three cases of Strychnine Poisoning, and record the important observation that the presence of phenacetin along with strychnine prevents the appearance of the typical reaction with bichromate of potassium. A very unusual case of Multiple Aneurysmal Disease is recorded by Mr. Cecil F. Beadles; there were found aneurysms of both carotid arteries at their bifurcations, several small cerebral aneurysms accompanied with gummatous formations, and dilatation of both coronary arteries of the heart. Notes of a case of Rupture of a Herniated Loop of Bowel by Sudden Contraction of the Abdominal Muscles are given by Dr. Alexander Miles.

POST-GRADUATE STUDY.

WE publish as a rule in the Students' Number of THE LANCET or in the issue following that number an account of the facilities given by the various medical schools and hospitals for post-graduate study. Post-graduate study is divided into three main divisions—the general study of professional subjects, including the special study of some branch, the study of state medicine, and the study of tropical medicine. We have described in the Students' Number the provision made for instructing graduates in the last two divisions, mentioning the procedure necessary to obtain diplomas or certificates for proficiency in them. The following article shows the principal arrangements existing for general post graduate instruction:—

LONDON.

The London Post-Graduate Association.—The London Post-Graduate Association is now so well known that it is hardly necessary to remind our readers that it is composed of the following hospitals and medical schools (general and special)—viz.: *General Hospitals:* Charing Cross, Guy's, King's College, St. Mary's, St. Thomas's, University College, and Westminster. *Special Hospitals:* The Brompton Hospital for Consumption and Diseases of the Chest, the Hospital for Sick Children (Great Ormond-street), the London School of Tropical Medicine, the National Hospital for the Paralysed and Epileptic (Queen-square), and the Royal London Ophthalmic Hospital (Moorfields). One ticket (the charge for which is 10 guineas for a three months' course, or 15 guineas for six months) admits the holder to the clinical instruction in the wards and out-patients' departments, the operations, necropsies, and other hospital practice of all the institutions mentioned above. The holder is also entitled to attend any special post-graduate classes which may be held from time to time at any of the general hospitals named. It is a result of the advances made in medical and surgical science during recent years that the practitioner who is unable to keep himself apace practically with these advances finds he is after a time at a great disadvantage. For the purpose of enabling qualified medical men to keep up to date in their work we can heartily recommend the scheme offered by the London Post Graduate Association, which thus places the best of all the hospital work in London at the disposal of its ticket-holders. The office of the association remains as before at the Examination Hall. Further particulars may be obtained by writing to the Secretary, the London Post-Graduate Association, Examination Hall, Victoria Embankment, London, W.C., or by personal application between the hours of 11.30 A.M. and 1 P.M., and 2 P.M. and 3 P.M. any week-day except Saturday.

Medical Graduates' College and Polyclinic.—This institution affords to medical practitioners special facilities for acquiring technical skill and for advancing their medical and scientific knowledge. The building contains lecture- and consulting-rooms, a pathological and clinical laboratory, a Roentgen-ray room, an ophthalmoscope room, a museum, a library, and reading- and waiting-rooms, &c. Cliniques are given each working day of the week except Saturday at 4 P.M., and a lecture on medicine, surgery, or their special

Army Medical Corps who have obtained leave for further professional study, and the certificate of attendance at the college during such leave is recognised by the Admiralty. The college is recognised by the University of London for hospital practice before the M.D. degree and by the Royal College of Surgeons for the necessary work before the Fellowship examination. The pathological laboratory has just recently been completely reorganised and placed in the hands of the pathologist, Dr. G. C. Low, who attends there during the whole day and gives instruction in Bacteriology and Microscopy and Tropical Medicine. A special class meets on three mornings a week from 11 to 1, and post-graduates joining the class can work in the laboratory at other times under the guidance of the pathologist. A class consists of 12 meetings and commences at the beginning of each month. The fee for this class in bacteriology and microscopy is £3 3*s*. The fee for the hospital practice, including all ordinary demonstrations and lectures, is £1 1*s*. for one week, £2 2*s*. for one month, £5 5*s*. for three months, £8 8*s*. for six months, £12 12*s*. for one year, and £25 for a life ticket; all fees to be paid in advance. A practitioner who cannot attend the whole course may attend any ten lectures or demonstrations during the session for a fee of £1 1s. A vacation class is held each year in August, the fee being £2 2*s*. for the course of one month, including hospital practice, or a ticket for a fortnight's hospital practice, including the lectures, can be obtained for £1 11*s*. 6*d*. The fee for a three months' course of instruction in the administration of anæsthetics, including a special class, is £3 3*s*., or without the class, £2 2*s*. A ticket for any of the above courses will be issued at any date. Arrangements can be made for gentlemen working for higher university examinations to be coached. The Winter Session commences on Monday, Oct. 7th. All communications to be addressed to the Dean, Mr. L. A. Bidwell, Post-Graduate College, West London Hospital, Hammersmith-road, W.

Hospital for Diseases of the Nervous System, 73, Welbeck-street, W.—A course of post-graduate lectures on diseases of the nervous system will be given at this hospital on Thursdays, at 5 P.M., as follows.—Oct. 17th: Dr. Harry Campbell, Selected Cases. Oct. 24th: Dr. T. D. Savill, Cases of Brachial Neuritis and Similar Conditions Involving the Arms. Oct. 31st: Dr. Purves Stewart, Cranial Motor Nerve Palsies. Nov. 14th: Dr. Dundas Grant, Some Forms of Nerve Deafness. Nov. 21st: Mr. Laming Evans, The Indications for Arthrodesis of the Shoulder Joint. Nov. 28th: Dr. F. S. Palmer, the Differential Diagnosis of Some of the More Common Types of Paralysis. Dec. 5th: Dr. E. Macnamara, Epilepsy.

North-East London Post-Graduate College.—This post-graduate school is established in connexion with the Prince of Wales's General Hospital, Tottenham, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees and by the India Office for purposes of study leave. Facilities are there afforded to qualified medical practitioners for taking part in the work of an active general hospital of 125 beds and for attending demonstrations of various branches of medicine, surgery, and gynæcology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anæsthetics, and dentistry. Cliniques, lectures, and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week except Saturday. Special classes, the attendance at which will be limited, are arranged in gynæcology, the surgical diseases of children, including orthopædic surgery, diseases of the throat, nose, and ear, diagnosis of diseases of the chest, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, analysis of gastric contents, clinical examination of the blood, diseases of the skin, abdominal surgery, radiography, bacteriology, and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month two guineas), and a perpetual ticket for the practice of the hospital may for the present be obtained on payment of a fee of five guineas. Medical practitioners who have attended a three months' course in any departments are eligible for appointment as clinical assistants in those departments. A certificate, signed by the staff, may be obtained at the end of three months' hospital attendance. A pathological museum and a pathological laboratory are available. A reading- and a writing-room, containing a reference and lending library, is provided, and tea may be obtained. The hospital is connected with the Telephone Exchange (No. 23, Tottenham).

The lecturers are as follows:—In General Medicine: Dr. Percy Kidd, Dr. R. Murray Leslie, Dr. G. P. Chappel, Dr. A. J. Whiting, Dr. A. G. Auld, Dr. T. R. Whipham, and Dr. D. Forsyth. In General Surgery: Mr. John Langton, Mr. Walter Edmunds, and Mr. H. W. Carson. In Gynæcology and Obstetrics: Dr. Arthur Giles. In Diseases of the Eye: Mr. R. Philip Brooks. In Diseases of the Ear, Throat, and Nose: Mr. H. W. Carson. In Diseases of the Skin: Dr. G. Norman Meachen. In Fevers (at the North-Eastern Fever Hospital, St. Anne's-road): Dr. Frederic Thomson. In Diseases of Children: Dr. G. F. Still. In Diseases of the Chest (at the Mount Vernon Hospital and the Northwood Sanatorium): Dr. J. E. Squire. In Tropical Medicine: Mr. James Cantlie. In Radiography and Medical Electricity: Dr. A. Pirie. In the Administration of Anæsthetics: Mr. A. de Prenderville. In Pathology and Bacteriology: Dr. Macdonald. In Clinical Pathology: Dr. Basil Price.

The opening lecture of the winter session, in conjunction with that of the North-East London Clinical Society, will be given at the hospital at 4 P.M. on Oct. 3rd by Dr. W. Hale White. Further information, with prospectus and syllabus of lectures and demonstrations, may be obtained from the Dean of the School, Dr. A. J. Whiting, 142, Harley-street, London, W.

PROVINCIAL.

Birmingham.—At the University of Birmingham special courses for post-graduates have not yet been instituted, except in the subject of Advanced Bacteriology (January to March) and Clinical Pathology and Bacteriology (April to June), but the various departments of the University are open to graduates who can attend any of the systematic courses on payment of a fee. Graduates may also work in the laboratories under the supervision of the professors for a small fee to cover the incidental expenses. Applications for information should be made to the Dean.

Bristol.—Courses of post-graduate instruction adapted to the requirements of those proceeding to the M.D. degree of the Universities, each lasting about 12 weeks, will be held at the Bristol Royal Infirmary and General Hospital. The course will consist of: (*a*) clinical demonstrations on cases selected from the wards and from out-patients in medicine, obstetrics, dermatology, and laryngology; and (*b*) tutorial classes in medicine, obstetrics, pathology, laryngology, bacteriology, and dermatology. Classes in clinical medicine will be held twice a week—once at the Infirmary and once at the Hospital—by Dr. J. E. Shaw and Dr. F. H. Edgeworth at the Infirmary and by Dr. J. Michell Clarke and Dr. J. O Symes at the Hospital. Classes in obstetrics will be held once a week on alternate weeks at the Infirmary and Hospital by Dr. Walter C. Swayne and Mr. D. C. Rayner respectively. A class in pathology will be taken once a week in the museums of the Infirmary and Hospital on alternate weeks by Professor Walker Hall and Dr. Carey Coombs respectively. Six demonstrations on dermatology will be given by Dr. J. A. Nixon and Dr. W. K. Wills at the Infirmary and Hospital. Six demonstrations on laryngology will be given by Dr. Watson Williams at the Infirmary. A practical course in bacteriology consisting of six demonstrations will be held by Professor Stanley Kent at University College. A tutorial class in medicine will be held on one evening a week by Dr. G. Parker, Dr. Newman Neild, and Dr. J. R Charles in rotation and a similar class in obstetrics will be taken once a week by Dr. Walter Swayne and Mr. Rayner alternately. The fees are as follows:—For the whole course, £7 7*s*.; for classes in clinical medicine, pathology, laryngology, and bacteriology and tutorial class in medicine, £5 5*s*.; for classes in obstetrics, pathology, and bacteriology, £3 3*s*.; and for clinical medicine and obstetrics only, £3 3*s*. Applications to attend the classes should be made to Dr. Walter Swayne, 56, St. Paul's-road, Clifton, Bristol.

Cambridge.—Long vacation courses are held at Cambridge during the month of July and the first fortnight in August. This year the course included lectures and demonstrations on general and special pathology by Professor G. Sims Woodhead, Professor Nuttall, Dr. Louis Cobbett, Dr. W. Malden, and Dr. G. S. Graham Smith on phagocytosis, the toxins and antitoxins, methods of standardisation, Meek).—The left elbow-joint had been freely opened, but it still contained some pus, and this was present also in the intermuscular planes outside the joint. The articular head of the radius possessed no cartilage cap and its end was rough and necrotic; there was also superficial necrosis of the humerus in the olecranon fossa, while the articular cartilage of the ulna was eroded and the subjacent bone showed commencing disease. There was a large abscess in connexion with the right hip-joint, which passed upwards and then forwards over Poupart's ligament into the extraperitoneal space in the iliac fossa, where it formed an encapsulated mass of the size of an orange, containing six ounces of thick, creamy, yellow pus. The neck of the femur showed necrosis and the articular cartilage was eroded. The bone at the bottom of the acetabulum was bare and necrotic, though there was no perforation. The serous cavities of the trunk were healthy. The intestines showed slight congestion of the lymphoid tissue. The liver and kidneys were pale, while the spleen was large and firm and of dark purple colour. The lower lobes of the lungs showed recent broncho-pneumonia with collapse. The heart valves were healthy but the myocardium was pale. The lymphatic glands both in the thorax and abdomen were large and reddened. The brain surface was flattened and covered with areas of purulent exudate, particularly along the course of the vessels. This condition was also very markedly present over the base of the brain, where there was excess of cerebro-spinal fluid. The choroid plexuses were infiltrated with pus. The grey matter of the cortex was softened and the lateral ventricles were distended with turbid fluid, while the third and fourth ventricles were little affected. No evidences of tuberculosis were found in the body.

Bacteriology.—Film preparations were made from the thick pus which was obtained from the elbow-joint. The microphages, which were by far the most common variety of cells in the pus, were full of minute rod-shaped bacilli which failed to retain Gram's stain. The pus was smeared on human blood agar and nasgar and incubated at 37° C. A good growth of minute, transparent colonies was obtained on the surface of both media. Each colony consisted of small Gram-negative bacilli. Cultivations which were made in liquid media remained sterile. Lumbar puncture was performed just before death and a few drops of turbid cerebro-spinal fluid were obtained. A pure culture of the influenza bacillus was grown from this fluid. A bacteriological examination was made after death with the following result. Hip-joint.—A pure culture of the influenza bacillus was obtained from the pus present in this articulation. Spleen.—The splenic juice was spread on tubes of blood agar and nasgar. A delicate growth of the influenza bacillus was obtained in each instance. Lung.—In the patches of broncho-pneumonia minute rod-shaped bacilli were found in some of the polymorphonuclear neutrophiles and also diplococci. No cultivations, however, were made from the lung tissue.

Remarks.—The primary lesion appears to have been epiphysitis of the upper extremity of the radius, but there was no evidence of any sore or wound on the limbs such as is sometimes met with in cases of acute epiphysitis and osteomyelitis due to the staphylococcus aureus. There was no history obtainable of any influenzal affection in any other member of the family, and apart from the fact that the child was not thriving for one month before the onset of this disease her condition caused no anxiety. When first seen the case appeared obscure and examination by x rays failed to throw further light on the exact lesion. This was doubtless due to the absence of ossification in the epiphysis and the very small amount of destruction of bone at the time this examination was made. At the post-mortem examination, however, there was irregular pitting at the upper end of the radial shaft which would have been rendered evident had a second skiagram been taken. The disease proceeded with great rapidity both in the elbow joint and also as regards the systemic infection, and the sequence following the radial epiphysitis appears to have been first the elbow-joint and then the right hip-joint, followed very closely by the diffuse meningeal infection, and terminating in acute broncho-pneumonia. From all these situations, except the lungs, the influenza bacillus was obtained in pure culture. The splenic juice gave a similar result, while microscopic sections of the lung showed a bacillus morphologically identical present in the polymorpho-nuclear neutrophils. The pus found in the elbow and hip joints and over the brain surface possessed no distinctive characters and has been described above.

An investigation of the literature on the subject of influenzal arthritis has shown no similar instance of multiple suppurative arthritis due to the influenza bacillus, and in very few cases of what is termed "post-influenzal arthritis" have cultures been taken, and so far as we can ascertain these have yielded a negative result. Nor have we been able to find records of a case of pyæmia proved bacteriologically to be due to this bacillus.

St. Thomas's Hospital, S.E.

RECORD OF CHANGES OBSERVED IN THE BLOOD COUNT AND IN OPSONIC POWER OF A MAN UNDERGOING A PROLONGED FAST.

By FRANCIS J. CHARTERIS, M.B. Glasg.,
ASSISTANT TO PROFESSOR OF MATERIA MEDICA, GLASGOW UNIVERSITY; DISPENSING PHYSICIAN, WESTERN INFIRMARY, GLASGOW.

The following observations were made upon a fasting man, B., who for the purposes of such scientific observations fasted for fourteen days. The primary object of the fast was to afford Dr. E. P. Cathcart an opportunity of examining the urinary excretions. The results of his observations have already been communicated to the Physiological Society. The fast took place in my house and I availed myself of the opportunity to keep a record of the blood changes. Similar observations have been made by Luciani[1] on the fasting man Succi and by Senator and Müller[2] on Cetti and Breithaupt. Neither of these records, however, give any information about the relative changes which take place in the white corpuscles though they note the number of red corpuscles, the percentage of hæmoglobin, and the number of white cells. Differential counts were made by Okintschitz[3] on rabbits deprived of food and water. Observations on the effect of starvation on resistance to infection have been published by Canalis and Morpurgo[4] and Roger and Josué.[5] An exhaustive index of the literature on inanition is given by Weber.[6]

Our experiment was divided into three periods. In the foreperiod the man was kept upon a constant diet and was in nitrogenous equilibrium. The fasting period lasted fourteen days. During it absolutely no food was taken, but a limited number of cigarettes was permitted which never exceeded two in the day. During the 24 hours one litre of ordinary tap water was consumed at the convenience of the subject. To obviate fraud the man was carefully watched day and night, and the analysis of the excretions show that the fast was genuine. At the close of the fasting period he was put upon a diet devised so as to contain no nitrogen. At the commencement of the experiment the man was in good health. His muscular development was excellent and he was not abnormally stout. When the fast began he weighed 10 stone 5½ pounds and at the close of the fasting period his weight was 9 stones 2 pounds 6½ ounces. The weighing took place at 9 o'clock in the evening when the patient was naked and just after the bladder had been emptied. During the fast the man remained in fair condition. There was a steady loss in weight and he became gradually less active. The mental condition did not appreciably suffer. He seemed to sleep soundly but complained that he dreamt of various kinds of food. As the fast proceeded he suffered very much from coldness and had difficulty in keeping himself warm.

The following table (Table I.) records the alterations which took place in the pulse, temperature, blood-pressure, and the blood condition during the fast. The temperature and blood-pressure were taken at the same hour in the evening, the latter being measured by Martin's modification of Riva Rocci's sphygmomanometer. The hæmoglobin was estimated by Gowers's hæmoglobinometer, and the corpuscles were counted with a Thoma Zeiss instrument. The films were stained with Leishman's and Jenner's stains.

The result of my observations may be briefly summarised as follows. The pulse slowed gradually as the fast proceeded. The man was aware of this fact from previous in "Practical Bacteriology" and "Pathological Histology" for graduates will be commenced in the pathological department of the Western Infirmary on Monday, Oct. 21st. The courses will extend over eight weeks, each class meeting thrice weekly. The fee for either course is £3 3*s.*, and for both courses £5 5*s.* In the Pathological Institute there is a limited number of rooms specially fitted up for research work and arrangements can be made for graduates who are desirous of engaging in work of this nature. Those interested in embryology may take out the practical course, or if they desire to do special work may obtain the use of a table in the embryology laboratory with such guidance and help as the lecturer can give. The University also has the right of nomination to a table in the laboratory of the Marine Biological Station at Millport. This station is happily circumstanced as regards the richness and variety of the fauna which can readily be obtained and kept alive in the tank rooms under approximately natural conditions. It thus offers facilities for various kinds of biological study and particularly for physiological and pharmacological work on the marine invertebrates. Further information regarding the station can be got from the honorary secretary, Mr. Geo. Middleton, 83, Bath-street, Glasgow. Post-graduate instruction in public health laboratory work is given in the university laboratory during both winter and summer sessions, and opportunities are offered under prescribed conditions for original research work. In physiology and materia medica such facilities as are possible are afforded to those wishing to engage in original research work. A course of lectures on Physiological Chemistry will be delivered in the winter months by Dr. E. P. Cathcart, university lecturer on Physiological Chemistry. It may be noted that new laboratories for physiology, materia medica, and public health have just been erected. These laboratories are provided with rooms suitably equipped for research work, in which graduates will be able to work in absolute privacy except in so far as they may wish advice and assistance from the teaching staff. Post-graduate class in Glasgow Eye Infirmary on Ophthalmoscopy and Refraction Testing, conducted by Freeland Fergus, M.D., will meet on Tuesdays and Fridays during October and November and the first half of December. Fee £1 1*s.* A class will also be conducted by Dr. Fergus on the Physiology of Vision during October, November, December, January, and February. It is open to practitioners and senior students and will be held in the Western Medical School. At the Maternity Hospital courses in midwifery commence every month. The fee for the first month is £2 2*s.* and later is £1 1*s.* per month. Those taking out this course see all the work of the hospital and are allowed to undertake obstetric cases and minor operations, both in the internal and external work of the hospital. The opportunities thus afforded are exceptional when we consider that each year on an average 20 Cæsarean sections are performed and forceps are used in 250 cases. At Anderson's College Medical School a six months' course of laboratory instruction in public health is given which is recognised by the Scottish colleges and by the University of Cambridge as qualifying for their Diplomas in Public Health. Supplementary to the laboratory work a three months' course of lectures is given when required on "Physics, Meteorology, Practical Sanitation, Sanitary Law, and Vital Statistics." By attendance on this course candidates for D.P.H. are exempted from three months of the necessary six months' outdoor work. Graduates desirous of taking out a course of operative surgery can obtain the necessary facilities by arrangement with the Dean of Anderson's College. At the Royal Infirmary two terms have already been held during the year, one in January and a second in May and June. These have proved most successful. The experience of last year showed that the medical men who attended the winter and spring courses were drawn mostly from the city and surrounding districts, whereas those who selected the autumn courses not only included a large number of country practitioners from the West of Scotland, but also graduates from abroad or from considerable distances. In making arrangements for the autumn session, beginning on Tuesday, Sept. 3rd, the staff have tried to meet the requirements of the latter by concentrating the courses within the period of one month and as far as possible filling up each day, while at the same time the time-table has been carefully arranged so as to avoid the hours of meeting interfering with one another. The hospital, owing to the enormous crowd of patients seeking relief within its walls and the abundant opportunities the wards afford of studying disease in all its phases, is specially well adapted for the carrying on of Post-graduate medical classes.

[3] Archiv für Experimentelle Pathologie und Pharmakologie, Band xxxi.

[4] Fortschrift der Medizin, 1890.

[5] Comptes Rendus de la Société de Biologie, 1900.

[6] Ergebnisse der Physiolog. Biochemie, 1902.

The syllabus includes the following lectures and demonstrations:—Clinical Medicine: Dr. T. K. Monro and Dr J. M. Cowan. Clinical Surgery: Mr. John Barlow, Mr Rutherfurd, and Dr. A. N. M'Gregor. *Hæmatology*: Dr Walter K. Hunter. Surgical Diseases of the Urinary Organs Dr. David Newman. Clinical Examination of the Urine Dr. John Henderson. Diseases of the Ear: Dr. J. Kerr Love. Demonstrations on Diseases and Injuries of the Eye Dr. A. Maitland Ramsay. *Diseases of the Throat and Nose* Dr. Robert Fullerton. Anæsthetics: Dr. J. King Patrick Gynæcological Pathology: Dr. W. D. M'Farlane. Electro Therapeutics: Mr. James R. Riddell. Gynæcology: Dr Balfour Marshall. Operative Surgery: Mr. Peter Paterson. *Bacteriology: Mr. David M'Crorie.*

The opening lecture will be given on Tuesday, Sept. 3rd, when the Honourable the Lord Provost of Glasgow will occupy the chair, and an address will be delivered in the dispensary hall by Sir Almroth Edward Wright of St. Mary's *Hospital, London. Application for these classes and demonstrations* should be made to Dr. J. Maxtone Thom, the superintendent of the infirmary, who will enrol members, supply copies of syllabus, and give any further information desired. Some of the classes must necessarily be limited as to number, it is therefore to be noted that enrolment to these will be made in the order of application.

IRELAND.

Belfast.—At Queen's College a course in clinical pathology, consisting chiefly of practical instruction, is given during the summer session, and, should a sufficient number desire to attend, a post-graduate course of practical work in the application of methods of chemical physiology to clinical investigation is also held. A course in clinical pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in this department for the public health committee of the *Belfast corporation* in connexion with water supply, sewage disposal, meat- and milk-supply, and the diagnosis of cases of infectious diseases. Subject to the number of students presenting themselves, arrangements are made for the necessary practical instruction (1) *in the chemical laboratories; (2) in the* pathological and bacteriological laboratories; and (3) for outdoor sanitary work under the medical officer of health of Belfast. These courses have been approved by the Privy Council in connexion with the degree of M.D. in State Medicine in the University of London. *The certificates of these courses* are also accepted for the diploma in public health granted by the Royal University of Ireland, the University of Cambridge, and the various licensing bodies.

Dublin.—Under the auspices of the Royal Colleges of *Surgeons in Ireland arrangements* have been made for conducting two courses of post-graduate study during each year in the months of June and September respectively. The instruction is given in the general and special hospitals of the city. A fee of £5 5*s.* is charged for each course. Particulars *of these courses* can be obtained from the Dean of the Medical School of the Royal College of Surgeons in Ireland.

In connexion with the Catholic University School of Medicine post-graduate courses are also held during the months of June and September. The fee for each course is £5 5*s.*, and application for particulars should be made to the Registrar of the Medical School of the Catholic University.

THE CONGRESS ON SCHOOL HYGIENE.—The French Minister of Public Instruction has accorded to Miss Alice H. Brunton, the daughter of Sir Lauder Brunton, the diploma of Officier de l'Instruction Publique in recognition of her services to the recent Second International Congress on School Hygiene.

REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.—The medical referees for Lanarkshire under the new Workmen's Compensation Act, which came into force in the beginning of July, have just been appointed. Under the old Act there were seven medical men appointed for the sheriffdom of Lanarkshire, but on this *occasion* the number has been reduced to five. They are as *follows*: Dr. James Barras, Dr. D. Macartney, Dr. D. Newman, Dr. J. C. Renton, and Dr. D. C. McVail.

compared with normal control animals. They hold that this depends upon the increased proliferation of the bone marrow which they have shown takes place during starvation.

Glasgow.

SOME CONSIDERATIONS ON EPIDEMIC CEREBRO-SPINAL FEVER.[1]

BY WILLIAM WRIGHT, M.D. GLASG., D.P.H. CANTAB.,
SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH, GLASGOW.

ALTHOUGH more or less extensive epidemics of cerebro-spinal fever have occurred in Europe for several hundred years, it was only recognised for the first time as a distinct disorder by Vieusseaux in Geneva in 1805. About the same time an epidemic occurred in the New England States and continued to prevail there for nearly a quarter of a century. Owing to the almost constant presence of a rash of a petechial character in those outbreaks in America the misnomer "spotted fever" was applied to it which ever since has been the source of much confusion not only to those members of the medical profession not familiar with it but also to the general public. It appeared in epidemic form in the South of France in 1837, spreading later to the North, numerous outbreaks occurring in that country until the year 1842. From 1846 to 1849 many fresh outbreaks occurred in France, when later it became widely diffused in Southern Italy. It made its appearance in Sweden and Germany in 1854, reaching its height in 1864. Dublin, Belfast, and Liverpool suffered from it in 1845 and again in 1866. Of late years it appears to have been widely diffused throughout the United States, where its area has extended from Canada to the Gulf of Mexico and from the Atlantic to the prairie States of Minnesota and Iowa. It prevailed during 1898–99 in a mild form, according to Osler, in 27 States of the Union and 1000 deaths occurred in New York city alone in the year ending February, 1905. Several outbreaks also occurred in Central Europe throughout 1905 and a number of doubtful cases in Northamptonshire early in the same year. The Local Government Boards of England and Scotland issued circulars to local authorities in September, 1905, calling attention to its existence in this country.

Glasgow epidemic.—The first authentic case occurred in Glasgow in March, 1906, and was removed to Belvidere Hospital. Numerous cases occurred thereafter and on account of its continued prevalence the corporation deemed it advisable to include it in the list of notifiable diseases. This took effect in Glasgow in August, 1906. From March to December, 1906, 205 cases came under observation by the health department here. Numerous cases occurred in Belfast and the disease was prevalent there in the spring of 1907. Early in the year I expressed the opinion that the disease was much more widespread than was generally recognised—in other words, that it existed in other cities and in all probability was being mistaken for other diseases. Since then cases have occurred in many towns in Scotland and in several in England. In investigating previous epidemics one is struck by the irregularity of their distribution and their peculiar commencement and cessation. The outbreaks appear in all instances in disconnected places and no well-defined channels of spread can be made out. Epidemics are generally localised and their duration variable. The same may be said of the outbreaks which are affecting this country at present. In those particulars, therefore, it differs from any of the acute infectious diseases, as, for example, small-pox, in which a definite epidemic curve can be traced and a connexion established from case to case.

Race and sex.—There is no racial disposition and the sexes are equally affected. The Glasgow figures for 1906 are: Out of a total of 205 cases, 121 were males and 84 females.

Age distribution.—Of 1267 fatal cases investigated by Hirsch 71 per cent. were under 15 years of age, 26 per cent. were between 15 and 40 years, and 3 per cent. were over 40 years. Of 105 consecutive cases admitted to New York Hospital in 1905:—

8% occurred at ages 1 year and under (youngest 4 months).
38% " " from 1 to 5 years }
23% " " " 5 " 10 " } 82% between 1 and
21% " " " 10 " 15 " } 15 years.
6% " " " 15 " 20 "
3% " " " 20 " 25 " (oldest 25 years).

Of 205 cases which occurred in Glasgow in 1906:—

18% were under 1 year (youngest 2 months).
12·2% were between 1 and 2 years.
5% " " 2 " 3 "
8% " " 3 " 4 "
12% " " 4 " 5 "
20% " " 5 " 10 "
10% " " 10 " 15 "
4% " " 15 " 20 "
4% " " 20 " 25 "
5% " over 25 years (oldest 52 years).

Some epidemics have confined themselves to adults in early middle life, as, for example, the Italian epidemic 1840–45 and the Alabama epidemic. Other instances of this peculiarity are the epidemics in camps and garrisons. Under one year it is more common than is generally supposed, and I am of the opinion that deaths certified as acute gastritis, teething and convulsions, and probably also summer diarrhœa may have been in some instances due to this disease.

Immunity.—Several rare instances of a second attack have been noticed in previous epidemics, and relapses may occur after the patient has apparently made a good recovery. The micro-organism may thus be capable of remaining latent in the cerebro-spinal fluid for a variable length of time and then take on renewed activity and virulence. No secondary attacks have occurred amongst any of the Glasgow cases. Relapses have taken place in a few instances.

Communicability appears to be very little. Previous epidemics have been recorded where a large proportion of the occupants of a jail, camps, and barracks have been affected. Several cases also have occurred in the same house sickening at or about the same time but the contagion seldom seems to linger and infect other occupants except in rare instances. Further, members of a family sleeping in the same bed with a patient usually escape, and medical men, nurses, and those who attend the sick are rarely affected. Of 205 cases which occurred in Glasgow in 1906 and 109 in January, 1907, in only 14 instances did two cases occur in one household and in two instances three cases.

Channels of infection.—No definite statement can be made at present. It is suggested that because a similar micro-organism has been found in the nasal secretions of many of the patients and others who have been in contact with the sick that this is the probable means of ingress. It is thought by others that as occasionally a history of a "fall on the head" is furnished, the filaments of the olfactory nerve having been injured or separated from the surrounding mucous membrane just as those filaments enter the cribriform plate of the ethmoid, a means of ingress is thus furnished. Others also support the view that it may find its way either by the veins or lymphatics in that region or by way of the frontal sinus, the tonsils, or the bowel. Nothing definite, however, has been done towards substantiating any of those theories. It is true that agglutination tests more or less satisfactory have been done with the blood of a recognised case or immunised animal with diplococci obtained from the nose, but much further research is necessary to arrive at anything like a definite conclusion on the matter. Since reading this paper, however, the micro-organism has been recovered by post-nasal swabbing from a fair proportion of the throats of "contacts" and it is assumed that those "contacts" may act as "carriers" (like diphtheria carriers) of the disease. It is to be noted, however, that of those "contacts" which did furnish a positive result after swabbing in Glasgow not one of them later developed the disease.

Climatic conditions.—The majority of epidemics occur in the winter and spring but some occur during warm weather. The Glasgow epidemic started in March, a cold month in this country, and continued in a mild form throughout the summer till the following December, when the cases became more numerous. The Belfast epidemic also occurred during the cold season. It has to be noted, however, that the Glasgow cases did not cease during the summer. It has been stated by eminent medical authorities that in all probability the cold season would see the end of this highly fatal malady in so far as this country was concerned. The history of previous epidemics in other countries does not support this view and it would appear that heat, cold, and moisture have little effect in influencing its activity. True, this summer (1907) there has been a considerable fall in the number of cases in Glasgow, but the disease is by no means stamped out and an increase may be expected during the winter.

Suggested sources of infection.—Randolph says that believed, to the effect produced by two bodies acting together: the one thermostable, known variously as the fixateur, substance, sensibilisatrice, amboceptor, &c., which was the essential substance. Alone it was capable of opsoninising, but its activity was greatly increased by the presence of free complement, known as "cytase," "alexin," &c. The amboceptor was present in very small quantities in normal serum, hence the apparent thermolability of the "opsonin" in normal serum, whereas in an immune serum the amboceptor played a predominant part, and though heating resulted in a loss of activity this was only partial. In both cases the loss was due to the destruction of the complement.

---

[1] A paper read before the Eastern Medical Society, Glasgow.

The subject was next approached from a different standpoint in a communication entitled

"*Absorption from the Peritoneal Cavity*,"

in which Dr. B. H. BUXTON (New York) referred to certain observations recently made in the laboratory of experimental pathology of the Cornell Medical College on the absorption of particles, such as typhoid bacilli, lamp black, and indigo, previously injected into the peritoneal cavity of the rabbit and the guinea-pig. In all cases there followed a rapid rush of the living or indifferent particles through the lymphatics of the diaphragm along the anterior mediastinal lymphatic trunks into the circulation. They were then rapidly deposited in various organs in such a way that they could not be removed by washing after bleeding the animal to death. Five minutes after injecting a large dose of typhoid bacilli into the peritoneal cavity the organism could be detected in considerable numbers in the peripheral blood of the ear in a free condition and not phagocytosed. At the site of inoculation the large mononuclear hyaline cells of Kanthack acted as macrophages and ingested particles with extreme rapidity. Polynuclear cells are largely absent from the normal peritoneal cavity and those present, usually eosinophiles, are practically inert, and it was not until a later stage that polynuclear phagocytes made their appearance. Dr. Buxton described the action of the macrophages in detail, especially with reference to those in the great omentum, and proceeded to say that from four to six hours after injection the bacilli in the deposited macrophages, unless polynuclear phagocytes had arrived in considerable numbers in the meantime, underwent multiplication and formed secondary centres of infection. Observations upon rabbits actively immunised by repeated doses of killed bacilli showed that their macrophages were capable of dealing with larger numbers of bacilli than those of the normal rabbit, and the contention was advanced that the increased resistance of the immune rabbit was entirely due to increased phagocytic activity. The immune animal possessed no greater bacteriolytic power than the normal one; it was further found that the bacilli were mainly destroyed extracellularly in the latter in contrast to the intracellular digestion of the bacilli in the former. These facts suggested that the rapid death of the normal animal was due to the action of the endotoxins set free by the extracellular destruction of the injected bacilli; while in the case of the rabbit that did not succumb so rapidly the fatal termination was due to generalised septicæmia. Here the number of endotoxins liberated from the fewer bacilli destroyed, while insufficient in amount to produce a rapidly fatal toxæmia, sufficed to inhibit the polynuclear invasion of the peritoneal cavity and so permitted the rapid multiplication of the undestroyed bacilli. It was concluded that the omentum played the chief rôle in the protection of the peritoneum against bacterial infection, partly by mechanical interception, partly by the vital activity of its macrophages.

Dr. J. CHARLTON BRISCOE (London), who followed, confined his remarks chiefly to

The Character of the Cells concerned in Phagocytosis and the Source of Opsonins,

and said that the cells which acted as phagocytes could be divided into two classes, the wandering cells and the fixed cells. The most important group of cells in the former class were the polymorphonuclear neutrophiles. Arnette had divided these cells into five groups, basing his simple classification on the form of the nucleus, or rather on the number of the component masses of nuclear protoplasm. The most vigorous phagocytes were found in the third of these groups which comprised cells with nuclei divided into three portions and considered by Arnette to be the adult form. More than four-fifths of the organisms ingested in an opsonin preparation were found in the cells falling under groups 1 to 3. Where leucocytosis occurred following an infection the increase was found in the cells of groups 1 to 3. The alveolar cells of the lungs, the large mononuclear cells found in the peritoneal cavity as the result of an injection of salt solution, some cells of the spleen, bladder cells, and endothelial cells of blood-vessels also acted as phagocytes in the presence of an opsonin. Dr. Briscoe then quoted experiments to show that opsonin was found in the fluid of the peritoneal cavity which normally contains no phagocytes, and that both in this fluid and in the blood the opsonin was considerably weaker if clotting was prevented. He drew the conclusion that opsonin and complement did not arise from the injury or death of phagocytes, as was held by Metchnikoff and his school, but that they existed in the circulating blood in an inactive form (? opsinogen) and that activation occurred as the result of clotting or shedding the fluid and suggested an analogy with fibrin formation. In support of this theory a further series of experiments was quoted. Certain clinical facts also lent support to this view. 1. The opsonic index in a case of septic endocarditis could be kept up by means of vaccine inoculations between 1·5 and 2 without any improvement occurring. 2. The cases which were most successfully treated by means of vaccine injections were those in which the lesion was localised—i.e., staphylomycoses. Here necrosis and fibrin formation occurred. 3. In a case of pulmonary tuberculosis under treatment by vaccine injections controlled by the opsonic index, in which a small hæmoptysis with formation of clot occurred, the bacilli in the sputum were found to be ingested by the alveolar cells and leucocytes. At other times the bacilli were free. Finally Dr. Briscoe quoted another experiment to show that when the serum of an immunised guinea-pig was injected into a normal guinea-pig the amboceptor or immune body could be detected in the urine. This indicated that the amboceptor was a foreign substance and probably the alteration had occurred as the result of clotting.

Dr. T. HOUSTON and Dr. J. C. RANKIN (Belfast) communicated a paper on

The Opsonic and Agglutinative Power of the Serum with Reference to the Meningococcus of Cerebro Spinal Fever occurring in the Belfast Epidemic,

in which they gave an account of their work with the meningococcus and its relation to cerebro-spinal fever. Using Wright's method they found that the blood of cases of cerebro-spinal fever, occasionally before, and almost invariably after, the fifth day showed a high opsonic and agglutinative effect with the diplococcus intracellularis of Weichselbaum. They pointed out that this method of agglutination as a test for meningococcic infection was perfectly satisfactory and gave results free from error. Of 114 different cases 40 were examined during the first five days of the disease; ten were positive—i.e., gave a high opsonic index and showed marked agglutinative power—and 30 were negative. Of the 74 cases examined from the sixth day onwards four were convalescent; of the remaining 70 examined from the sixth to the 133rd day of disease 68 gave a positive and two a negative reaction—that is, of the cases examined by this method after the fifth day 97·1 per cent. gave the positive double reaction. As a rule, this reaction disappeared soon after the fever subsided. While the opsonic power was largely destroyed by heat and rapidly diminished on keeping the serum the agglutinative power was much more stable. Their results showed, too, that the cerebro-spinal fluid always exhibited much lower opsonic and agglutinative powers than the blood serum collected at the same time. From a study of races of meningococci obtained from Great Britain, Germany, and America, and their reactions with the blood of undoubted cases of cerebro-spinal fever, they came to the conclusion that this disease was due to a meningococcus having invariably the same opsonic and agglutinative reactions. They also brought forward evidence to show that at least one variety of Gram-negative coccus corresponding closely in cultural characters with the diplococcus intracellularis of Weichselbaum was capable of producing meningitis. This coccus differed from the meningococcus of epidemic cerebro-spinal fever both in its opsonic and agglutinative reactions.

Dr. DAVID LAWSON (Banchory) then detailed some observations upon

The Elimination of Opsonins by the Excretory Organs

which had been carried out in the Banchory Laboratory in

There is no characteristic temperature, however, and the temperature curve is usually erratic. It is, as a rule, elevated at first, then irregularly remittent or intermittent. The pulse also is of the febrile type. It has to be noted, however, that during the restless periods when the face is flushed the pulse is usually rapid and weak, and conversely when the child is lying quietly the face is pale and the pulse slow and stronger. Tache cérébrale can frequently be brought out. The pulse-respiration ratio is seldom disturbed. If there should be any alteration in this respect pneumonia should be looked for and the meningeal symptoms explained as being due to pneumococcal infection.

Rash.—Herpes around the nose and mouth has been fairly common in the Glasgow cases, but in only a small number has any rash on the body been observed. In several instances a few pale, faded, purple spots, petechial in character and not unlike old flea-bites without the central punctate spot, have been noticed. In several others definite purple hæmorrhagic irregular spots, singly and gathered into groups at places, presenting when in clusters quite the look of small nævi, have also been seen. But what would appear to be the true rash of cerebro-spinal fever when it does occur, and I recollect seeing it in only a few instances, is a sight once seen never to be forgotten and presents a picture which amply justifies the American *nom de plume* of "spotted fever." A medical man confronted with a picture such as I am about to describe in a case in which there is evident meningeal mischief is safe in making a diagnosis of cerebro-spinal fever. The spots appear in all instances within from three to four hours of the onset of illness. In describing one case I practically illustrate the others.

Two hæmorrhagic spots with irregular edges of about the size of a lentil and maroon in colour were seen on the inside of the right thigh. It is definitely stated that no other spots were present elsewhere on the body at this time. The parents were early alive to the possibility of the case being one of "spotted fever" on account of the constant warnings in the press and kept a careful watch on the progress of the rash. The medical attendant was called in early and he fully confirmed their statements which were to the following effect. Spots appeared within the next hour on the feet, legs, and hands, and an hour later there were many on the abdomen, back, and neck. During the hour following several showed on the upper and lower eyelids; at the same time a distinct hæmorrhage was noticed on the conjunctivæ of both eyes at their outer canthi. They definitely appeared therefore in crops, as did all the rashes in the other few instances in which I have been fortunate to observe it. The duration of the interval in this case, as in another during which those spots made their appearance, was as short as four hours, and no further spots came out after eight hours from the onset of illness. In the other cases, however, crops in decreasing numbers appeared during the course of the first few days of illness. In the two cases above specially mentioned the rash was so profuse as to render it just possible to place a shilling-piece on the skin without overlapping those on the front of the body, although on the back a florin might with equal result have been used. All the spots when they appeared were definitely maroon in colour and in the course of an hour or so had quite changed to purple and dull purple. The spots varied in size from that of a pin point, a lentil, to that of a quarter of an inch square, and in some places where they were gathered in clusters they were even larger. They were all irregular in contour, not raised from the surface of the skin and did not disappear on pressure.

Sequelæ.—Deafness is the most common and is not usually associated with otorrhœa. Permanent squint and other affections of the eye sometimes occur. Mental weakness or confusion after recovery occasionally happens and sometimes more or less paralysis of locomotion.

Anomalous forms.—Among the anomalous forms perhaps the most important is the *ambulant* type which, however, is very rare. In the *abortive* form the onset is of the usual severe character but the symptoms subside in a day or two and convalescence is rapid. An *intermittent* type is occasionally encountered in which there are alternate remissions and exacerbations, but when the temperature has been taken regularly it has been shown that the remissions are more apparent than real. This form is distinguished from the *chronic* type which may last for months and is characterised by a series of recurrences, reducing the patient to a condition of extreme marasmus. The emaciation is so great in those instances as quite to merit the term "skin and bone."

Prognosis.—The prognosis is uncertain and should always be guarded. It is exceedingly grave when the onset is sudden and severe without prodromal symptoms. In less severe cases a wide distribution of the symptoms showing that there is a correspondingly wide involvement of local nervous structures is of serious import, and cases in which coma develops seldom or never recover.

Mortality.—The mortality in different epidemics has varied as much as from 20 to 75 per cent., that for Glasgow for the year 1906 working out at over 66 per cent.

Remedy.—No specific has yet been found for the disease and the various sera which have been employed would appear to have produced little beneficial effect. The treatment therefore resolves itself into the adoption of such measures as are found useful to relieve symptoms. Cold to the head and spine applied by means of a bladder of ice or an ice-cap and a spinal ice-bag is approved by some, and blisters to those parts is recommended by others. Frequent bathing is believed to be useful and wet cupping applied to the nape of the neck to relieve headache is suggested by Osler. Mercury has been tried and found useless. Most observers agree in favour of opium by the mouth notwithstanding that during the course of the disease dysphagia is a common symptom. Morphine in large doses hypodermically has frequently been found useful when given early. The injection of antiseptic fluid into the dural sac has been praised by eminent authorities. If it were possible thoroughly to wash by this means the affected area without undue damage it is unquestionable that good results would follow.

Bacteriology.—The causative micro-organism is the diplococcus intracellularis meningitidis, sometimes called for short the meningococcus. Probably the most correct term is micrococcus meningitidis cerebrospinalis, or the micrococcus of cerebro-spinal meningitis, as although the organism is usually found in pairs they occasionally occur in tetrads and grouped as staphylococci. It was discovered by Weichselbaum in 1887, who showed that it was clearly distinguishable from the diplococcus pneumoniæ. In shape it closely resembles the gonococcus and is found in varying numbers generally within the leucocytes, though more or less abundant groups of cocci may also occur outside the bodies of those cells. It stains readily but is decolourised by Gram's method. It grows at a temperature between 25° and 42° C., the optimum being 37° C. In 24 hours colonies develop on agar or blood-smeared agar plates which are as large as two millimetres in diameter, at first clear and glistening, becoming greyish-white and later brownish in colour. The edges of the colonies are smooth, undulating, and translucent. Blood agar or serum agar, or, better still, nutrose ascitic agar, are the best media. It grows readily in broth and better if blood or ascitic fluid be added. It cannot grow under strictly anaerobic conditions. As it readily dies out in culture media it is necessary to make subcultures daily or every second day. The organism possesses a very low degree of resistance to desiccation, 24 hours' drying at a temperature of 37° C. being enough to kill it. It is only feebly pathogenic to animals, even white mice resisting subcutaneous inoculations. Intraperitoneal injections, however, usually produce death in from 24 to 48 hours. Guinea-pigs are even less susceptible, and rabbits as a rule not at all. The serum of patients and animals (sheep, horse) has been found to agglutinate cultures in low dilutions but this work is still in its experimental stage.

Lumbar puncture.—To perform the operation the patient should lie on his side with the knees drawn well up, the head bent down, and the spine arched backwards. The skin over the lower lumbar spine is then thoroughly washed with soap and water, and thereafter treated with ether. Whilst this is being done a syringe with a long needle is being boiled at hand. The spinous process lying nearest to the line joining the highest points of the iliac crests is that of the fourth lumbar vertebra. The puncture is made midway between this spine and the one next above or below it and about half an inch from the middle line. The direction given to the needle should be forwards, inwards, and upwards, and in infants almost straightforwards. When the needle has been pushed firmly onwards fluid will be seen entering the syringe. Suction by the piston is unnecessary. The fluid obtained is usually opalescent. Films are then prepared, stained, and examined in the ordinary way. Thereafter the fluid is centrifuged and the deposit is examined for the tubercle bacillus. Finally some of the fluid is transferred to culture media and placed in the incubator to serve for future examination. Lumbar puncture is resorted to on every possible occasion by the health department, and every spirochæta pallida were accepted as diagnostic then their demonstration before the appearance of secondary symptoms made the institution of active treatment essential. Silver spirochætæ were held to be definitely proved to be real, and the various reasons for this view were referred to. This method was most useful when the smear method failed. By its aid spirochætæ and syphilis were proved to be associated, but that the spirochæta pallida was the actual cause was still awaiting proof. The inoculation experiments were referred to as strengthening the position of the spirochæta pallida and as proving the reality of the silver spirochætæ.

Dr. BUSHNELL read a paper describing

A Case of Mycosis Fungoides in its Relation to Infection and Malignant Disease,

in which he said that the case of mycosis fungoides which he referred to had been studied as one of a series of examples which showed the close and important interrelationships existing between inflammation and malignant neoplasm. In the premycotic stage as well as in the later evolutionary period the disease was a granuloma characterised by diffuseness and absence of capsule formation. In the evolutionary stage when rapid tumour formation supervened it bore a close resemblance to sarcomatosis as evidenced by its rapidly fatal course and the arrangement of its cells and fibres quite comparable to lymphosarcoma.

Dr. CAREY COOMBS (Bristol), described

The Myocardial Lesions of the Rheumatic Infection.

He declared his intention of confining his remarks to an account of his own observations on the earlier acute phenomena of rheumatic myocarditis in preference to the residual lesions of later years. First referring to the macroscopical changes he recapitulated the dilatation of the ventricles and the consequent stretching of the auriculo-ventricular rings; aggravated and perpetuated by the atony of the myocardium combined with the associated pericardial adhesions often associated with, but not essential to, the establishment of more or less extensive hypertrophy. The post-mortem records of some of the Bristol hospitals included 89 cases of rheumatic carditis occurring in patients under the age of 16 years. In 51 of these cases the weight of the heart and the age of the patient were both recorded and when analysed showed that in patients with pericardial adhesions the age averaged 11 years and the heart weighed 15 ounces; with valvular sclerosis the age was 14½ years and the heart weighed 12 ounces; with established lesions of both serous layers the age was 15 years and the heart weighed 30 ounces; with early lesions of both serous layers the age was 11½ years and the heart weighed ten ounces. Next, dealing with microscopical changes, the only trustworthy one was fatty changes in the parenchyma, shown in sections along the fibres as irregularly quadrilateral areas scattered through the myocardium, the earliest globules at the poles of the nuclei, the largest at the centre of the cell, and best demonstrated by staining with Sudan III. or Herxheimer's Scharlach R solution. In the opinion of Dr. Coombs the most characteristic of the interstitial changes was the formation of knötchen or submiliary nodules situated in the subendocardial and subpericardial tissues and in the vicinity of the medium-sized and smaller arteries, in some cases in such intimate association as to appear to arise from the adventitia of the arteriole. These nodules contained characteristic cells, arranged in more or less regular whorls, spindle-shaped or oval, the long axis measuring about ten times the diameter of an erythrocyte and containing more than one nucleus. The nuclei stained deeply with Weigert's hæmatoxylin: the cytoplasm, relatively small, stained deeply with thionin. The nature of the cells was obscure, but they were probably the product of connective tissue proliferation in response to an irritant.

Dr. J. J. S. LUCAS (Bristol) then detailed his

Notes on a Case of Pericardial Calcification

which had been observed in the Bristol county asylum. The entire pericardium, with the exception of a small area at the apex some two inches square, was completely calcified, but no signs of ossification could be detected throughout its extent.

Next came two communications from Dr. ALDO CASTELLANI (Ceylon) which in his absence were read by the Secretary of the Section (Dr. R. V. SOLLY of Exeter). The first,

A Note on the Spirochæta of Yaws (Spirochæta Pertenuis),

described the morphological characters of the spirochæta associated with this disease and its minute histological structure, from a consideration of which Dr. Castellani stated his opinion that the spirochætæ of yaws and of syphilis were totally separate and distinct species. With regard to the incidence of spirochæta in patients suffering from yaws and in monkeys experimentally inoculated, Dr. Castellani's results can best be appreciated when presented in tabular form.

Material examined.	Man.		Monkey.	
	No. of cases.	Positive findings	No. of cases.	Positive findings.
1. Primary lesion	6	6	16	15
2. Unbroken papules of the general eruption	76	73	3	2
3. Ulcerated papules of the general eruption	76	62		
4 Blood of general circulation	20	*Nil.*	15	*Nil.*
5. Spleen juice	5	3	4	3
6. Lymphatic glands	11	6	11	6

From the facts relating to the practically constant association of spirochæta and yaws, the successful results obtained by inoculating the monkey with material containing spirochæta only, and the failure to infect the monkey when similar material had been freed from spirochæta by filtration, the author concludes that yaws must be considered a form of spirochætosis or treponemosis, and that the specific causal agent was in all probability spirochæta (or treponema) pertenuis.

Dr. CASTELLANI also communicated a

Note on a Bacillus found in a Case of Gangrenous Appendicitis,

in which he detailed observations that led him to believe that the organism was causally associated with the disease.

The proceedings of the section were concluded by two communications by Dr. A. F. DIMMOCK (Harrogate) and Mr. F. W. BRANSOM, F.I.C. The first,

A Note on a Method of Estimating Creatinin in Urine,

described a modification of Folin's picric-acid test and was performed by adding to 10 cubic centimetres of the urine 15 cubic centimetres of a saturated solution of picric acid and then 5 cubic centimetres of a 10 per cent. solution of sodium hydrate. After standing for five minutes the mixture is made up to 500 cubic centimetres by the addition of distilled water and its colour compared, in an instrument termed a "chrometer," with that of a standard solution of potassium bichromate. (This standard solution contains 24 54 grammes $K_2Cr_2O_7$ per litre and the colour value of 8 milligrammes of potassium bichromate is stated to be equivalent to 10 milligrammes of creatinin.) The chrometer consisted of a dark chamber with an eye-piece inserted in the top. On looking through the eye-piece two discs of light were visible in the floor of the dark chamber. Inside the chamber and directly over the discs of light were two glass tubes, the one containing the solution to be tested and the second the standard solution, each connected with a levelling tube placed outside the dark chamber. By raising or lowering the levelling tubes the columns of liquid in the tubes in the chamber were raised or lowered until the colour of the test liquid matches that of the standard solution as observed over the disc of light. Finally, the estimation of the amount of creatinin in the specimen was estimated by reading off the height of a pointer outside the apparatus on an attached scale.

The second communication by the same authors,

A Note on a Method for Determination of Sugar in Urine,

also involved the use of the chrometer. The process is as follows:—To 50 cubic centimetres of urine add 12·5 cubic centimetres of a 50 per cent. solution of sodic hydrate; boil for one minute, filter and cool; pour the mixture into one of the tubes of the chrometer and into the other tube fill a standard solution of glucose similarly treated; match up the colours in the two columns of fluid by adjusting the levelling tubes and read off the amount of sugar on the attached scale by means of the pointer.

cachexia"—i.e., the general condition of ill-health, which includes the wasting of the body and its death. A study of the results obtained from medicinal treatment of such various conditions brings important facts to light and helps to clear the ground for the discovery of an instrument of destruction for the disease when first diagnosed.

Except in the cases mentioned at the commencement of this paper no results can be claimed which can be called certain results upon an external growth of any long standing, but in several cases the diminution in size of lymphatic glands secondarily infected has been marked, and no fresh invasion of lymphatic glands has been noted after the commencement of treatment. This observation is important, because the lymphatic system is so frequently the path by which infection travels. In two cases of abdominal cancer, both diagnosed by surgeons of repute after an exploratory operation, a complete restoration to health has been obtained. The first of these cases was published in the *British Medical Journal* of Oct. 28th, 1905. The patient was under the care of a medical man who obtained from me the details of treatment: he was able to report to me in October, 1905:—"The tumour is no larger, I think it is smaller; there is no pain, although this was present before the commencement of the treatment; the general health is very good, better than for some time previously." It is only right to say that the operating surgeon when a report was sent to him wrote:—"About the diagnosis, it was wrong. I have little doubt in the light of subsequent events that what we took to be carcinomatous nodules must, I suppose, have been inflammatory. Yet I erred with my eyes open, because I have already read a paper which was afterwards published on this very condition." The query is, perhaps, pertinent: What is the disease which can so deceive a surgeon of experience and two other medical gentlemen present at the operation? And how many of the successes claimed by surgeons are cases of this unknown disease?

The second case came under my care during the last winter. The patient was operated upon by Mr. A. A. Bowlby in St. Bartholomew's Hospital in April, 1906, who found a cancer of the liver. After operation the patient was told that this was incurable and that nothing further could be done for her. When I first saw this patient she was losing flesh, was in pain, and was suffering from slight jaundice. She has just now returned from a convalescent home and has been examined at St. Bartholomew's. Her condition is most favourable, she herself believing that she is absolutely cured. No judgment as to permanence of cure can be given for many years, but at all events the fact remains that the woman's life has been prolonged and she has obtained alleviation from her sufferings.

Two cases of obstruction of the gullet have been certainly relieved. The first was treated by Mr. C. B. Lockwood at St. Bartholomew's Hospital, to whom I am eternally indebted for the interest which he has taken in my work. His house surgeon wrote to me on Dec. 12th, 1906: "One of Mr. Lockwood's patients who is suffering from cancer of the gullet has greatly improved on your treatment. After ten injections he has put on a stone in weight and from being practically unable to swallow fluids can now take about a pint in five minutes." This patient died unfortunately from bronchopneumonia, as was ascertained by the necropsy, and not from the disease.

The second case was treated by myself. The patient refused operation when pressed to submit to one by an eminent surgeon in October, 1906. He came under my treatment early in November and was then losing 4 pounds in weight weekly. His powers of swallowing increased and he first ceased to lose, and then gained, weight. Six weeks before death he gradually began to lose ground and the obstruction gradually increased until death occurred, eight months after our first interview.

The escape from surgical methods in these two cases, although life was not saved, implies a considerable advance. Palliative methods which are available for the surgeon do not provide anything but a life of misery to the patient, and further work on chemical lines is encouraged by such results. Such work is proceeding.

As coöperation was found to be difficult in this country a report was obtained by Dr. Morgan from a laboratory in Buffalo, New York, which recommended a reinforcement of the coumaric acid salts at present used, and resulting from this various metallic salts are being tried. It appears probable that if the right combination can be secured success will follow, but no definite decision can be given on this point at the present moment.

Very definite results have been obtained in connexion with the prevention of the local death of the tissues invaded and the absorption of the products of decomposition into the human economy. In old days my experience was that a large proportion of patients died septic, while no case which I have treated by the new method has so died. The reason for this is probably that all the drugs used are very active in destroying fission fungi, those agents at once of destruction and disease. When tested by the Rideal-Walker method against the bacillus typhosus, the activity of carbolic acid being 1, that of tylmarin was found to be 4·5 and that of the ortho-coumaric acid 6·5, whilst that of formalin, which is a very active substance, is only 0·30.

In connexion with the prevention of the cancerous cachexia it is no part of my present intention to enter upon the various complex elements which cause it. It is, however, clear in my mind that the treatment advocated produces a great stimulating effect and consequently a prolongation of life and increase of comfort to the sufferer. For many years past physicians in this country have been too much led instead of themselves leading. Many have been content with a profound scepticism as to the results obtained by the use of the curative part of their art, many with the copying of foreign methods and modes of thought, and too many with just the use of any new drug introduced by manufacturers. It appears to me that it should be the rôle of the physician to initiate rather than to follow, and that the present pessimism as to the possibility of treating cancer by therapeutic methods is an attitude to be ashamed of. At no time have so many active remedies been in the hands of physicians and at no time have there been so many suggestive facts obtained from scientific laboratory researches for their use. At the present moment surgery is supreme simply because medicine has so long suffered from time-honoured prejudices and a reluctance to emerge from beaten tracks.

Hatfield.

THE SOLUBILITY OF AIR IN FATS AND ITS RELATION TO CAISSON DISEASE.[1]

BY HORACE M. VERNON, M.D. OXON.,
FELLOW OF MAGDALEN COLLEGE, OXFORD.

(*From the Physiological Laboratory, Oxford.*)

As is now well known, the very varied symptoms produced by rapid decompression from high atmospheric pressures, and popularly known as "caisson disease" or "diver's palsy," are due to liberation of bubbles of gas—chiefly nitrogen—in the blood and tissues. In the course of a recently published investigation I found that air is much more soluble in certain oils than in water. Dr. J. S. Haldane pointed out to me the interest of this fact in connexion with the causation of caisson disease and at his suggestion I have repeated and extended my observations.

The fats experimented with were olive oil, cod-liver oil, and lard. In the case of the first two the solubility was measured at 15° and at 37° C., whilst for lard it was determined at 45° C. In the observations made at room temperature the oil was shaken violently with air in a bottle for several minutes and was allowed to stand for from one to one and a half hours till all the air bubbles had risen to the surface. It was then weighed, and about 40 to 50 grammes of it were sucked up into the vacuous flask of a Geissler's mercury pump. This flask contained from 70 to 100 cubic centimetres of 0·5 per cent. sulphuric acid which had previously been well boiled for an hour so as to get rid of all traces of air. The mixture of oil and water was now boiled for half an hour, the oil breaking up into a very fine emulsion and giving up practically all of its gas in the first few minutes. This gas was pumped off and analysed with Haldane's[2] gas analysis apparatus. The oil was boiled with dilute acid instead of water, so as to obtain the whole of the carbon dioxide present, both combined and in solution. In determining the solubility at 37°, the oil, previously saturated at room temperature, was gland a curious cell with two nuclei apparently encapsuled, and subsequently abnormal cells of diverse types. Reference was made to a new species of trypanosome found in the blood of an Indian bullock at Singapore in which cell forms were found resembling those occurring in sections made by Dr. Mott and Dr. Stewart taken from glands of dogs inoculated nine months previously with the blood of a horse suffering from the secondary stage of dourine. A microscopic section (shown) demonstrated in a dourine gland that the lymph spaces were filled with vacuolated cells, in some of which granules occurred which stained blue with a modified Giemsa stain. Many of them appeared as structureless chromatin particles or even as small masses of pigment, but some consisted of a nucleus and a cell protoplasm with a staining reaction of somewhat different shade from the containing cell; and in the majority of cases there was a small chromatin body resembling a micro-nucleus occurring either as a minute round dot or as a short rod-shaped particle. Within these large vacuolated cells also were found elongated protoplasmic bodies with two or more nuclei. Yet another cell type was met with as an inclusion, consisting of a crescentic chromatin body with some pink staining protoplasm attached to the concave margin. The interpretation of the various observations recorded was not attempted; further investigations were requisite to determine whether the bodies noted were minute abnormal lymphocytes or arose from endogenous cell formations, or whether, on the other hand, they were resting or protoplasmic forms of the trypanosomes.

[1] A paper read before the Royal Society on May 30th, 1907.

[2] Haldane: Journal of Physiology, vol. xxii., p. 465, 1898.

Dr. BALFOUR described

A Peculiar Blood Condition, probably Parasitic, in Soudanese Fowls.

When investigating the spirillosis of fowls in the Soudan Dr. Balfour found a spirillum identical with the Spirillum gallinarum and that the parasite was communicated by the fowl tick, the Argas persicus. He observed during these investigations that many fowls exhibited a very curious condition affecting the red corpuscles, and that although the fowls so infected presented symptoms very similar to those exhibited by fowls suffering from spirillosis the temperature curve and the post-mortem findings markedly differed. The temperature, which was normally about 108° F. in the rectum of healthy Soudanese fowls, fell during the illness to 102° or lower just before death. In blood corpuscles when stained by Borrel blue and eosin or by Leishman and Giemsa stains the bodies in question were found in the extra-nuclear portions of the red blood corpuscles. They might be close to the nucleus or at the outer edge of the corpuscle and they varied in number from one to seven in each corpuscle as well as in size and shape. These bodies did not exhibit the stains usual in hæmatozoa and there were appearances which suggested the presence of chromatin either as a single dot at the pointed end of a plume-shaped form or as a series of dots arranged usually at fairly definite intervals round a spherical or diamond-shaped body; or scattered irregularly about a spherical form. By artificial light these dots showed the true chromatin-red colour. In addition, there were masses or streaks of the same material. The intra-corpuscular bodies were unpigmented and very resistant. Post-mortem findings showed no gross lesions. Dr. Balfour believed the bodies he described to be hæmatozoa belonging either to a new class or as identical with the piroplasm of the bird. He based his conclusions on the appearance of the fresh blood, the results obtained by the modified Ross method of staining, the general arrangement of the stained parasites in the corpuscles, the possible formation of tiny spores, and the association of the bodies with a definite disease.

Captain S. R. CHRISTOPHERS, I.M.S., contributed a paper on

The Development of Piroplasma Canis in the Tick.

In previous communications Captain Christophers had described in the tick R. sanguineus fed on dogs infected with piroplasma canis the club-shaped bodies of Koch and had given a description of developmental stages of piroplasma canis leading up to the formation of swarms of sporozoit-like bodies in the salivary glands of the nymph and adult of the second generation. In the present communication Captain Christophers had filled up gaps and corrected certain errors of interpretation, so that now the cycle of development of the parasite in the tick could be clearly followed. One feature in the developmental processes noted was that after reaching a certain size an achromatic line divided the parasite into two parts of almost equal size, one containing the chromatin mass whilst the other contained no chromatin. These portions separated except at one point and became arranged so that the chromatin half became the anterior portion. The club-shaped bodies thus formed became vermicular in appearance at the anterior end, left the gut, and occupied the ovary and oviducts. In many ways the piroplasma resembled the development of the malarial parasite, but in the former the zygotes seldom went through division into sporozoits in the cell originally invaded, and the sporozoits when formed were more or less disseminated through the tissues. The concise history showed that a parasite in the gut of the adult tick enlarged and became a motile club-shaped body which left the gut and penetrated an ovum where it became a zygote. The zygote enlarged and broke into sporoblasts which disseminated in the tissues of the larva. In the glands of the nymph miniature sporozoits had collected and in the glands of the adult mature sporozoits were found.

Dr. GEORGE A. WILLIAMSON (Cyprus) contributed

A Further Note on Bilharzia (Schistosomum) Disease in Cyprus.

In 1902 Dr. Williamson reported a case of bilharzia in Cyprus and from the same district of the island three persons came under his notice during March, 1907. At Morphou he found an endemic centre of the disease; of eight children at the local school five were found to have blood and ova in their urine; the villagers at Morphou stated that the disease occurred in persons who bathed, waded, or fished in the water in the bed of the river Syrianokhori. Amongst females who did not frequent the river no infection was found.

Lieutenant-Colonel C. BIRT, R.A.M.C., from observations during eight years in South Africa related his experiences of

South African Diseases.

Enteric fever was widely prevalent and differed in no detail from that met with in Europe. Kaffirs suffered severely from typhoid fever. Abortive typhoid fever causing fever lasting for from two to 10 days had been proved to exist not infrequently, the Widal reaction in each case proving positive; these mild cases were dangerous, as the patients frequently went about and thus disseminated the disease by infecting watercourses. Flies and ants no doubt served also to spread enteric fever. Lieutenant-Colonel Birt spoke favourably of Wright's typhoid vaccine; not only was the incidence of the disease reduced by half but when typhoid fever did occur the mortality of the inoculated was just half that of the un-inoculated. The use of inoculations during typhoid fever was also advocated. Dysentery and diarrhœa caused nearly one-fourth of the total number of deaths in Johannesburg. Shiga's bacillus was found in half the cases examined; amœbic dysentery was proved in one of the 55 cases reported upon. Multiple hepatic abscesses were found in 28 out of 58 necropsies of dysenteric fatalities. Lieutenant-Colonel Birt found anti-dysenteric serum efficacious in many cases of dysentery. Pneumonia was very prevalent amongst Kaffirs and tuberculosis was responsible for about one-sixth of the total mortality among Kaffirs. Bilharzia was endemic in Northern Nigeria. Mediterranean fever was endemic in many districts of the Orange River Colony where goats provided the milk-supply. Malaria was rarely met with in Harrismith, Bloemfontein, or Pretoria.

Lieutenant-Colonel BIRT also contributed a paper on

Mediterranean Fever in South Africa.

He regarded subcutaneous inoculation of minute doses of micrococcus Melitensis vaccine as highly beneficial in Mediterranean fever and quoted several other observers who supported its efficacy.

Dr. CHARLES BEGG (Bath) sent a paper on

Complications Found in Chronic Cases of Sprue.

He regarded sprue as an invasion of the mucous membrane of the intestinal canal by microbes causing a chronic form of destructive inflammation and considered pancreatitis a frequent complication. Careful analysis of the fæces and urine showed that the pancreas was the cause of the intestinal disturbance and the pancreas could often be felt to be enlarged, more especially in the left hypochondrium. A second frequent complication was chronic appendicitis, and in a third the liver and gall-bladder became involved.

Mr. JAMES CANTLIE (London) said that he found ipecacuanha a most trustworthy and efficient remedy in sprue. The drug was given as for dysentery and ipecacuanha above-described method are invalidated, or liable to be invalidated, by leakage of air into the vacuum pump. This is not the case if due precautions are taken. The pump must be in such good order that no appreciable leakage occurs when it is left vacuous for several days, and it must be kept vacuous for a week or more before use, for if air be left in it a small amount attaches itself to the glass walls of the apparatus and only escapes slowly when the pump is made vacuous again. Air likewise attaches itself to the walls of the boiling flask, but it is got rid of by the preliminary boiling of the dilute acid previous to the introduction of the oil. In all analyses of gases, whether in oil, water, or salt solutions, such a preliminary boiling was invariably adopted, and by taking these precautions many hundreds of analyses have been made without invalidation of results by leakage of air. I have elsewhere[9] recorded nearly a hundred analyses of the gases in sea water, and the mean nitrogen values then obtained are almost identical with the nitrogen absorption values determined by Dittmar.

The bearing of the above recorded results upon many phases of caisson disease is probably a direct one. The commonest symptoms observed in caissoniers consist of joint and muscular pains, and in paralysis, the latter being the result of injury to the spinal cord. Thus in necropsies on caissoniers Bert observed softening of some inches of the spinal cord in the dorsal region. Von Leyden, in a case of death 15 days after decompression, observed signs of myelitis and small irregular fissures in the mid-dorsal cord, probably produced by the escape of gas. Necropsies on divers have shown necrobiosis and hæmorrhages in the spinal cord[10] and distension of the blood-vessels by air bubbles.[11]

Chemical analysis shows that spinal cord and peripheral nerves contain nearly 20 per cent. of fat and fat-like substances. Adipose tissue contains about 83 per cent. of fat, and yellow bone marrow (as distinct from red marrow, which is poor in fat) contains no less than 96 per cent. of fat (Gorup-Besanez). If these tissues were saturated with nitrogen at, for instance, four atmospheres of atmospheric pressure, 100 cubic centimetres of them would contain, instead of the $0{\cdot}975 \times 4 = 3{\cdot}90$ cubic centimetres of dissolved nitrogen present in an equal volume of water, about 7 cubic centimetres in the case of the spinal cord and nerve and 20 cubic centimetres in the case of yellow bone marrow. On sudden decompression, therefore, the volume of nitrogen bubbling off in a gaseous form might be from two to six times as much as that from the non-fatty fluids and tissues of the body.

It has been found that the severity of the symptoms developed by caissoniers is influenced greatly by the time of exposure to increased pressure. In sinking the foundations of a bridge at St. Louis a pressure reaching at a maximum to 50 pounds above normal was used and a large proportion of the workers were affected. As the depth of the caissons increased the shifts were shortened from four hours to one hour, with the result that the serious accidents were reduced to *nil*.[12] Presumably, therefore, the body tissues were not so fully saturated with nitrogen in the shorter as in the longer period. On the other hand, Hill and Greenwood[13] found that on exposing themselves to a pressure of from 30 to 45 pounds their urine became saturated with the theoretical amount of nitrogen in from 10 to 15 minutes. This quicker saturation must be due to the blood flow through the kidney being much more rapid than that through the spinal cord, and very much more rapid than that through adipose tissues. Even if it were as rapid through fat-containing tissues as through the kidney, the fats, in virtue of their greater solvent power, would take longer to become fully saturated than the fluids of non-fatty tissues.

Conclusion.—At body temperature fats dissolve more than five times as much nitrogen as an equal volume of water or blood plasma. The special tendency of the fat-containing tissues (such as subcutaneous tissues, spinal cord, and peripheral nerves) of caisson workers and divers to suffer injury from the liberation of gas bubbles after rapid decompression is dependent on this great solubility.

Oxford.

A CASE OF SELF-INDUCED (?) ABORTION.

By A. B. M. THOMSON, M.B., CH.B. EDIN.

THE occurrence of foreign bodies in utero is not so frequent as one might expect. Hellier[1] accounts for 127 cases in literature and records one of his own. As an additional case and also for its medico-legal interest the following is worthy of record.

The patient, a married II.-para, aged 30 years, was first seen on the evening of June 26th, 1906. Her illness was attributed to a hearty meal of fish, of which she had partaken a few days before. She had a history of persistent pain in the abdomen and vomiting; incidentally it was mentioned that she had aborted. The product of abortion had been disposed of, but I was assured that "everything had come away." The peculiar odour of a purulent post-partum discharge was distinctly noticeable in the room. The patient's temperature was 102° F.; her pulse was 130, small, and running; in addition she had the icteric tint and the apathy which are associated with septicæmia. Her abdomen was slightly distended, tympanitic, and tender, more especially in its lower part. On examination per vaginam a thin rod was found projecting for about 1 inch beyond the patulous os. Considering the gravity of the case I asked my colleague, Dr. John McDonald, to see the patient in consultation, to which request he very kindly acceded. When we removed the foreign body it was found to be an ordinary bone penholder, 4 inches in length, the rounded and pointed end of which had been introduced into the cavity of the uterus. The patient, although vague in her other statements, maintained repeatedly that she herself had induced the abortion. She died on the morning of the 27th, just 12 hours after being first seen.

Necropsy.—The brain was normal. The left lung was emphysematous and the pleura was adherent along the lateral border of the chest wall, evidently the result of a past pleurisy. On opening the abdomen the bowel was found distended with flatus; there was no evidence of peritonitis either general or pelvic, although a few loops of small intestine lying in the pouch of Douglas were red and injected. The spleen was much enlarged and semi-diffluent so that its removal intact was a work of some difficulty; it weighed 28 ounces. Before dissecting out the organs of generation *en masse* it was noted that the uterus was moveable and enlarged. There was a purulent discharge coating the walls of the vagina, but there was no sign of laceration. The uterus measured 6 inches in length, 4½ inches in breadth at the fundus, 2 inches in depth, and its walls were ¾ inch in thickness. The os was patulous but without trace of any recent wound. On opening the uterus the placenta was found on its posterior wall; it was greenish at the margins with a dark, punctured wound in its centre. The end of the penholder fitted into this wound in the placenta. The left ovary contained a corpus luteum. The size of the uterus confirmed the patient's previous statement that she was between the third and fourth month of pregnancy.

The question which called for decision was whether this was in reality a case of self-induced abortion. Is it possible for a woman to introduce into her uterus, without causing injury to the vaginal walls or to the os, a straight rigid rod four inches in length? The only answer one could give was that in this case it was possible but very improbable. There was no condition present, such as prolapse, which would have rendered the introduction of the rod easier. If the patient herself introduced the penholder she must have become an adept, because there was no trace of violence having been used to insert it into the proper axis of the uterus, which was normal. On the supposition that this case was self-induced, another interesting point arises. The penholder had been left in utero to act as a bougie. This is unusual in cases of instrumental criminal abortion. The object, as a rule, is simply to "draw blood" from the uterus, and rarely is the instrument left *in situ*.

Perhaps, in conclusion, I may be permitted to express the opinion that instrumental criminal abortion is fairly frequent, judging from the number of cases of septic gaps a century ago, are now of no avail. A simple man-of-war's man in the making costs the country hundreds of pounds and years of laborious training. Even humble lower deck ratings rise in value with startling rapidity. The skilled marksman is an asset who any day may be priceless to his country. Once lost he cannot be replaced while a modern war is in progress. How he is put out of action—whether by the enemy or by disease—matters not; he is gone all the same. Our bluejackets are our heart's blood. When it must flow, it is surely our sacred duty to see to it that we at least shall not be responsible for wastage.

---

[1] Practitioner, February, 1906.

Fleet-Surgeon A. GASKELL, R.N., communicated a paper on the

Treatment of Wounded in Fleet Actions.

He contended that a hospital ship should be built during peace time so that experiments could be made and the men trained. Two types of hospital ships would be probably wanted—an ocean-going type and one for coasting service. A dry antiseptic large dressing was required for a first aid dressing for use in the navy; it should consist of a pad of modified Gamgee tissue nine inches square, with a four-inch roller bandage made of Lister's carbolic gauze, and a large safety-pin, the whole being wrapped up in a calico envelope. The ordinary brown haversack of the gunner's stores was suitable for holding a supply of first-aid dressings, and one of these sacks should be hung behind each gun and in other convenient places. In regard to medical preparations for battle he suggested, if time allowed, that everyone in the ship should receive a hot antiseptic bath and should have served out to him a complete war clothing consisting of non-inflammable flannel impregnated with double cyanide salt. As much as possible of the body surface should be covered, even to the extent of wearing flannel masks with openings for the mouth, nose, and eyes. That war clothing could be sterilised and stowed away for use in war time. The Japanese in their last war ordered the men to bathe and to wear clean clothing before going into action. He thought that the ideal station for medical officers was an armoured receiving room capable of holding 6 per cent. of the ship's company. Such a receiving-room would have to be thought of during the time of constructing the ship. In ships already built he suggested that a large space should be cleared near the bottom of the ship and approached through one or more large armoured tube-like hatchways. During a fierce action the wounded should not be moved. The details of moving the wounded when feasible should be settled at the time by the principal medical officer.

Lieutenant-Colonel A. M. DAVIES, R.A.M.C., contributed a paper on

Enteric Fever: its Spread by Personal Infection, and Preventive Measures on Active Service.

He discussed the spread of enteric fever by personal infection and quoted from Osler, who admitted that "the possibility of direct transmission through air from one person to another must be acknowledged." If that assumption were granted it would be found to explain a large proportion of the incidence of enteric fever under active service conditions. In regard to preventive measures, *the stools and urine being the obvious channels of infection*, the chief care in regard to disinfection and disposal should be directed to the excreta. But the date of commencement of infectivity was not known with certainty in the case of urine or stools, nor was it known precisely when they ceased to be infective. To deal with a convalescent so as to insure that his stools and urine were not a danger to others might be tedious but it was not very difficult. It was not intended that there should be any relaxation of the means at present acknowledged to be necessary for safeguarding or purifying water and food supplies and keeping the camp clean. There were, however, certain special lines on which rational enteric prophylaxis should be carried out on active service, and these he summarised as follows: No enteric case and no man suspected to be suffering from enteric fever should remain in camp—that is, under "at the front" conditions (even in field hospitals) if enteric epidemics were to be stopped at their commencement. All concerned should be constantly on the look out for a suspicious case; all such cases should be immediately segregated, and a diagnosis should be arrived at as quickly as possible with the modern methods now at their disposal. All diagnosed cases and all suspicious cases should be removed to an environment where thorough treatment such as would prevent their being a source of infection to others could be carried out.

Fleet-Surgeon P. W. BASSETT-SMITH, R.N., read a paper on

The Frequency of Aneurysms in the Royal Navy.

He furnished statistics and details of the aneurysms he had noted at Haslar Hospital during the last seven years, and observed that the greatest frequency in incidence was found in the stoker ratings and next in the petty officers, who were predisposed by their more advanced age and by the strenuous life led in attaining their positions. He remarked that although it was generally held that syphilis and alcoholism were common predisposing causes of aneurysm, nevertheless in the histories of his series of cases he had been unable to find any definite proof of the constant occurrence of either one or the other. It was evident that the conditions of life under which men worked in the navy favoured very markedly the development of aneurysms and it was to be hoped that the system of developing the body by means of the Swedish drill under medical inspection might have a beneficial effect.

Staff-Surgeon G. E. DUNCAN, R.N., gave a demonstration of a Form of Oral Filter to be worn during operations.

THURSDAY, AUGUST 1ST.

Surgeon C. K. BUSHE, R.N., read a paper on the

Treatment of Syphilis Afloat.

He described the system which he had introduced into the Royal Naval Barracks at Devonport. He observed that in the majority of cases of recent venereal sores it was not possible to make a definite diagnosis of constitutional syphilis and the appearance of further signs had to be awaited before a diagnosis could be made. The patient was placed on the sick list and the sore was treated with a non-specific local application, usually iodoform. The patient received no specific treatment internally. If the sore healed without constitutional manifestations appearing the patient was discharged to duty but continued under weekly observations for three months, his name being entered on the syphilis observation list. Men on that list had to present themselves each week for examination by the medical officer. If men on that list were drafted elsewhere they were followed up by a reference sheet addressed to their commanding officer with the request that the men might be brought to the notice of the medical officer and a few particulars of the case were also furnished. It was admitted by most of the leading syphilographers that the plan of waiting for secondary symptoms to appear did not influence detrimentally the subsequent cure of the disease or detract from the chances of a cure being effected. All men placed on the syphilis observation list were warned of the reasons for their being kept under observation. When a diagnosis of constitutional syphilis was made the man was put on the sick list under specific treatment and on an unstinted diet until all active signs of the disease had disappeared, when they were discharged to duty; but they remained on the syphilis treatment list. The men were made acquainted with the nature of the disease and the necessity for continuous treatment over a long period. When iodide of potassium was given it was administered by the mouth with ammonia largely diluted and in conjunction with mercurial intramuscular injections.

Staff-Surgeon H. L. NORRIS, R.N., communicated a paper on

Wireless Telegraphy and Hospital Ships,

in which he pointed out that the necessity of hospital ships for naval warfare had been widely recognised and these ships could be fitted out so quickly on the outbreak of war that the various navies would be well provided with them in the next naval war. For the thorough performance of her duties a hospital ship must be on the scene of action as soon after a battle as possible, so that it was essential that she should be furnished with some means for keeping in touch with the fleet. In consequence of the provisions laid down by the Hague Conference it was advisable that hospital ships should carry a wireless telegraphy installation, but such means of communication might on the outbreak of war be declared contraband. It was to be hoped in case of war that this means of communication would be granted to hospital ships, otherwise their efficiency would be seriously impaired.

Lieutenant-Colonel R. CALDWELL, R.A.M.C., read a paper on

Enteric Fever during Active Service.

He declared that the causation of epidemics of enteric fever was closely connected with the faulty disposal of excremental matter. He described how in an outbreak of attacks vary infinitely in different persons they are always or nearly always similar in the same patient; and that the incomplete attacks and the initial symptoms of the complete attacks are identical." The different stages of the fits, the various types of fit, and the varieties of warnings are carefully described, and the sequelæ are considered in detail. Among the types of the disease, major, minor, and combined forms are differentiated and the severer types of serial epilepsy and status epilepticus are separately described, the former being regarded as a mild and modified form of the latter.

An important chapter deals with the mental states found in epilepsy, comprising the pre- and post-paroxysmal psychoses, with special references to acute dementia and mania. The psychical epileptic equivalents are also discussed in some detail and presented in a clear and satisfactory manner, the classification given being a very useful one. The relations of epilepsy to other neuropathic conditions, and its association with other morbid states are next considered. A chapter on the Pathology of Epilepsy, by Dr. John Turner, is a valuable addition. Dr. John Turner discusses in detail the morbid changes observed by himself in a number of cases and compares them with those found by other authorities. He describes changes in the meninges, in the neuroglia, in the nerve cells, and in the blood-vessels. Notably, he finds that atrophy and sclerosis of some part of the central nervous system occurs in more than half the cases of idiopathic epilepsy. It is, however, to the changes in the blood-vessels that he attributes the greatest significance—viz., intravascular thrombi, either of hyaline or granular material. He believes that the immediate cause of the fits is cortical stasis resulting from obstruction to the blood supply by intravascular clotting in a defectively developed nervous system; that the blood platelets play an important part in this clotting, and that the atrophy and sclerosis are late results of the vascular changes. This view is ingenious and is supported by very careful observations, but it appears to us difficult to reconcile in its present form with Herpin's law previously enunciated as to the identity of type of the fits in a given case.

The various bio-chemical and other theories of the genesis of epilepsy are critically considered in a separate chapter, and the conclusion arrived at is that some types of epileptic paroxysm may probably be the result of auto-intoxication. Lastly the diagnosis, prognosis, and treatment of epilepsy are given in detail. The remarks on treatment are especially valuable as the various forms of treatment are given, with practical details and with statistical tables as to their utility. Some interesting remarks in regard to epileptic colonies are appended and there is a useful paragraph on epilepsy and life assurance, with especial reference to the insurability of a person subject to fits.

Dr. Aldren Turner's book is a very notable addition to the literature of epilepsy and we have read it with interest. It should serve as a very useful work of reference.

Differential Diagnosis and Treatment of Disease: A Text-book for Practitioners and Advanced Students. By AUGUSTUS CAILLE, M.D., Fellow of the New York Academy of Medicine; Member and Ex-President of the American Pædiatric Society; Professor of Diseases of Children, New York Post-Graduate Medical School and Hospital; Visiting Physician to the New York Post-Graduate and German Hospitals, &c. With 228 illustrations in the text. London: Sidney Appleton. 1906. Pp. 867. Price 25*s.* net.

To present the methods employed in the diagnosis and treatment of disease in such a manner as to be readily available for the practitioner and to include a description of those procedures originally worked out and employed by the specialist has been the task which Dr. Caillé has set himself in writing the book before us. He deprecates the arbitrary division of diseases into medical and surgical groups and desires to "re-establish the relations of internal medicine, surgery, and the several specialties." In his introductory remarks he outlines his views as to the position of the general practitioner in relation to the community on the one hand and to those practising as consultants on the other. He should be "the trusted family counsellor in all matters concerning health and sickness." To insure the confidence of those among whom he practises, thinks Dr. Caillé, it is necessary, above all things, that he should be a sound diagnostician and a master of physical diagnosis; he should have had some laboratory training and be capable of making a thorough clinical examination, employing all the ordinary methods of investigation; and he should further possess a good knowledge of hygiene and dietetics, be an adept at minor surgery, and be able to perform emergency operations.

Dr. Caillé's book is written primarily for the general practitioner and for the advanced student to supply them with the means of making a diagnosis and of ordering treatment. The first chapter is devoted to clinical methods and gives directions for the general, regional, and special examination of the patient with clear and practical accounts of the ordinary laboratory methods as applied to the investigation of the urine, fæces, gastric contents, sputum, exudates, puncture fluids, blood, and calculi. The second chapter deals with the general therapeutic management of patients, with direct reference to various methods of treatment, especially those involving manipulative measures such as lavage, rectal feeding, and baths, which are carefully described in considerable detail with explanatory figures, many of them reproductions from photographs. The third chapter, one of the longest and at the same time one of the best in the book, is devoted to pædiatrics. It practically constitutes a small treatise on the diseases of children. It includes directions for the general management of the sick child with a careful and detailed account of the various methods of infant feeding. This chapter bears the impress of the author's practical experience, especially in regard to treatment. Seven chapters are then given up to a consideration of diseases of the digestive organs. The first of these deals with food and dietetics, and here various dietaries are described and long lists of food substances are given, but without sufficient details as to their selection and to the quantity which should be given. The diseases of the various parts of the alimentary canal are separately considered in the other chapters; the methods employed for diagnosis are described and in many cases illustrated, including such processes as trans-illumination of the stomach. Some conditions, notably diseases of the pancreas, are very superficially considered and in others the directions as regards treatment are too general and frequently inexact. Diseases of the circulatory system are next discussed. In this section, again, some important subjects are dismissed with but short consideration. To give an example, the diagnosis of aneurysm, especially of aneurysm of the aortic arch, is very briefly described, while the treatment of aneurysm in general occupies eight lines. It is further stated that if the physical signs of aneurysm are not conclusive an exploratory needle puncture may be made, a procedure which we must emphatically describe as certainly useless and possibly dangerous. The treatment of the various blood diseases is also far from being as complete as it might be. In describing the conditions giving rise to lymphadenitis and to enlargement of lymphatic glands they are all classed under the general term lymphoma, which is liable to give rise to considerable confusion, that word being usually restricted to the enlargements of lymphadenoma or Hodgkin's disease.

Diseases of the respiratory organs are dealt with next, and

THE PATHOLOGICAL MUSEUM.

A wise mountaineer pauses from time to time to survey the prospect, to examine his immediate surroundings, and to take his bearings in relation to the path already traversed and the best route by which to reach his objective. So also is it wise for a seeker after truth to pause occasionally, to take stock of his position in relation to established *facts, to grasp* the bearing of his researches upon the practical workaday world, and the lines best suited for future investigation. The annual Pathological Museum of the British Medical Association affords an unequalled opportunity for such a survey of the situation. Moreover, to many practitioners this is the one occasion each year when they can refresh their early teaching, keep in touch with the recent advances of medical *science*, and bring these advances to fruition by improved methods of treatment in their own practice. We have repeatedly dwelt on this aspect of the museum and cordially congratulate the medical profession in Exeter, the museum committee, and the honorary *secretaries (Dr. R. V. Solly* and Dr. G. P. D. Hawker) *on* the excellence of this year's museum. The labour involved in collecting, classifying, and labelling material from distant parts is far greater than the uninitiated would imagine, and greater than that in any other section of the Association. The special subjects selected for demonstration this year were diseases of the breast, the brain and spinal cord, the *liver* and gall-bladder, tropical diseases, cancer, and radiograms of fractures and dislocations. Of the first named there were 90 specimens (60 from St. Bartholomew's Hospital, London, and 30 from the Cancer Hospital, London, Cambridge, Bristol, and other places), the finest series we have seen in one place outside the Hunterian Museum, collected and classified mainly by the energy of Mr. E. H. Shaw and Mr. W. S. Handley. The other series were also very good. Some years ago we advocated informal demonstrations of the specimens by their exhibitors and this year fixed demonstrations were given by Dr. F. W. Mott and Dr. E. F. Bashford on syphilitic lesions and on cancer respectively. Several of the exhibitors were at hand to describe their specimens and we believe it would add to the interest of visitors if all exhibitors could be urged to attend and give informal demonstrations as far as their other engagements would permit.

Syphilis and Parasyphilis of the Central Nervous System.

On Thursday at 9.30 A.M. Dr. Mott demonstrated this exhibit. The first case was one of multiple gummata of the brain in a woman, aged 35 years, with symptoms resembling general paralysis of the insane. Histological lantern slides exhibiting the granulomatous deposits of syphilis and syphilitic endarteritis were shown. Specimens were also demonstrated from a case of syphilitic gummatous meningitis in a girl, aged 16 years, who presented Hutchinson's teeth and other signs of congenital syphilis. Attention was drawn to the likeness of the lymphocytic and plasma-cell infiltration in these cases to the infiltrations met with in sleeping sickness in man and dourine in horses, a point of much interest when it is remembered that syphilis is coming to be regarded as due to one form of protozoon, the spirochæta pallida, and the two last-named diseases to another and closely related protozoon, the trypanosome. Specimens from cases of juvenile general paralysis of the insane, which has been shown by *Dr.* Mott and others to be a parasyphilitic disease (i.e., a disease due to the remote effects of syphilis), were next exhibited, and the characteristic changes in the cerebral cortex were demonstrated. The pyramidal and other cortical cells become gradually *destroyed* and the peripheral processes become corkscrew-shaped by reason of their severance from the attachments at their cortical surface. Tabes dorsalis is another parasyphilide, and cases of tabes in the husband and of general paralysis of the insane in the wife were shown on the screen. It was mentioned that it had been shown that the antibodies of the syphilitic toxin are present in the cerebro-spinal fluid of patients suffering from both of these diseases.

Cancer.

On Friday Dr. Bashford demonstrated the specimens and charts exhibited in the museum. Clinical, pathological, and histological investigations had defined the essential characteristic of cancer to be the power of proliferation possessed by circumscribed groups of cells. These methods of investigation had failed to solve the problem *they* had defined and resort to experiment became necessary. The starting point of experiment was the transference of cancer from one animal to another and the determination of how it was effected. There was no doubt that the experimental transference of cancer simply meant *the* continuation of the growth of the cells *transferred and not* the development of cancer *ab initio.* The method of transference was explained in *detail.* A chart of the clinical course of a primary (spontaneous) tumour of the mamma was exhibited. It showed that recurrence had followed two attempts to remove it completely. *After* the first, *recurrence took* place within a fortnight, after the second only after three months. Owing to the short duration of *life in mice the relief* thus afforded represented a period of many years' freedom in the case of the longer-lived human subject. Dr. Bashford explained that it was only by surgical means that relief could be given to mice suffering *from spontaneous or implanted* cancer.

The results of implanting the tumour removed at each operation and at death were also exhibited on the same chart. This showed that in some mice the implanted fragments progressively increased and ultimately attained enormous sizes. In other mice they grew for a time, after which growth ceased either temporarily or permanently (spontaneous cure). In yet other mice the implanted fragments did not grow at all. The tumours which developed were represented in natural size so that a marked contrast was evident between the amount of growth which took place in the inoculated animals and that which occurred during the same time in the original mouse. The chart brought out very clearly the enormous proliferation following the distribution of fragments of a tumour over a large number of normal animals. Dr. Bashford explained that the experimental study of cancer resolved itself really into the study of growth which was the only property common to malignant and benign tumours. Features in growth which pointed to the alternation of phases of increased and diminished energy of proliferation of the cells were described, and their apparent bearing on the clinical course of cancer in man was alluded to, attention being especially directed to the sudden manifestation of enhanced degrees of malignancy in the case of tumours previously growing slowly. The fact that spontaneous cure certainly occurred in mice was not to be used as implying that mouse cancer and human cancer differed materially, but to be taken as implying that the reports of the disappearance of malignant tumours in man were worthy of more credence than had usually been given to them.

A number of slides were shown illustrating the features of cancer of the mamma in mice in cases of spontaneous and experimental tumours. Particular attention was directed to slides of an epithelioma capable of transplantation from mouse to mouse with retention of its typical epitheliomatous structure. It was claimed that the parallel in the behaviour between the two groups of tumours dissipated all doubts that the mammary tumours were not cancerous. For the rest Dr. Bashford's demonstration covered the ground of a paper by himself and Dr. J. A. Murray in our columns of March 23rd of this year,[1] together with a discussion of the nature of cancer and of the protection which can be conferred on mice, reported in our columns on July 6th.[2]

In a corner of the museum, *too late for cataloguing*, were six microscopic specimens and coloured sketches bearing on experimental production *of* cancer and its histological transformations after transplantation, exhibited by Professor Ehrlich (Frankfort): (1) Chondroma nine times transplanted *from* mouse to mouse; (2) a carcinoma transplanted 56 times from mouse to mouse; (3) fusiform-celled sarcoma produced by transformation of a mammary carcinoma in a mouse; (4) colonies of a sarco-carcinoma in process of transformation by artificially treating the inoculating media; (5) sarco-carcinoma; and (6) mixed-celled sarcoma produced by transformation of a mammary carcinoma *of* a mouse. It has long struck pathologists that the histological divisions of the carcinomata and sarcomata are *artificial* and these specimens emphasise this view. No wonder histologists differ as to the precise nature of a *microscopic specimen* and may even be unable to agree whether a certain growth is malignant or non-malignant.

study of the subject of gynæcology and who require guidance in their actual practice. The first part of the book is devoted to a discussion of what may be termed generalities, such as the consideration of the meaning and practice of asepsis and antisepsis and the relative advantages of each method. Then follow chapters in which the various methods of examining gynæcological patients are discussed, including a description of the different positions employed. Special care has been taken in the descriptions of the minor operations of gynæcology, which are described in detail, as is, too, the treatment of the patient subsequently to operation. The affections of the vulva, vagina, Fallopian tubes, and ovaries are next considered in order. In discussing herpes of the vulva the author mentions the interesting fact pointed out by M. Fournier that this disease is very constantly met with in cases of chancre of the cervix. Indeed, in any cases of herpes of the vulva, for this reason, the cervix should be examined with special care. In the section on diseases of the vagina the various methods of treating troublesome cases of cervical endometritis are described very fully. A good deal of space is also devoted to the interesting and important question of congestion and sclerosis of the uterus. A good point in each section dealing with the different diseases is the large amount of attention which is given to the indications for the various forms of treatment recommended and the great value which is assigned to strict conservatism in the operative procedures recommended. In the chapter on the treatment of retro-deviations of the uterus by operation statistical tables are given, showing the immediate and remote results of such operations as ventro-fixation, shortening of the round ligaments, and vagino fixation. In comparing the two tables of the results of total abdominal hysterectomy and subtotal abdominal hysterectomy for fibroid tumours of the uterus it is interesting to note that the mortality of the 823 cases of the former operation is 72, or 11·4 per cent., while the mortality of the latter operation amongst 2426 cases is 191, or 12·7 per cent. These results are in agreement with the opinion held by many surgeons at the present time that there is very little to choose between the mortality of these two procedures. After a very careful examination of the advantages and disadvantages of the abdominal route in the treatment of cancer of the cervix the author comes to the conclusion that abdominal hysterectomy for this disease is only justifiable in certain conditions—namely, when the vaginal operation is contra-indicated by extreme narrowness of the vaginal canal or when it is probable that a cancer which has to a slight extent invaded the tissues outside the uterus possibly may be entirely removed by the abdomen when this could not with certainty be accomplished by the vagina. This book undoubtedly gives a full and clear account of the important facts of gynæcology; it is based very largely on the teaching of Professor Richelot, who contributes the preface.

LIBRARY TABLE.

Medical Lectures and Clinical Aphorisms. By SAMUEL GEE, M.D.Lond., F.R.C.P Lond., Honorary Physician to H.R.H. the Prince of Wales and Consulting Physician to St. Bartholomew's Hospital. Second Edition. London: Henry Frowde and Hodder and Stoughton. 1907. Pp. 307. Price 5s. net.—We would especially draw the attention of our readers to the discourse on "The Nature of Asthma." The remarks formed a lecture given before the Royal College of Physicians of London on March 23rd, 1899. After a careful survey of the various theories which have been suggested as to the pathology of asthma, Dr. Gee arrives at the conclusion that the doctrine of spasmodic asthma is very imperfectly supported by facts, and he believes that "all asthma" is merely a peculiar form of bronchitis and that there is no need for any hypothesis of spasm in order to explain the phenomena of the disease. He considers that in all probability the "bronchia" are obstructed both by secretion and swelling. There are other questions, however, to which he gives no answers, in reference to certain points connected with the "asthmatic tendency." In what does it consist? Why are some persons prone to asthmatic catarrh and others not? Why does the disposition run in families? What is the bond which in so many cases connects the several diatheses of asthma, eczema, and gout? Until these problems receive attention we cannot agree with Dr. Gee in his theories as to the nature of the disease, although his remarks are highly suggestive. The "Clinical Aphorisms" afford interesting reading. They will probably be more interesting to the senior members of the profession, though some of them may well be taken to heart by younger practitioners. Patients are naturally desirous of obtaining an exact prognosis. It is often difficult, however, to turn from physician to prophet, and most observers will agree with the following: "Never give a definite opinion as to how long a patient suffering from phthisis will live, for the only certainty is, that if you do, you will be wrong."

The Relation of Man to the Animal World. By Sir SAMUEL WILKS, Bart., M.D. Lond., F.R.S. Hampstead: The Priory Press. Pp. 34. 1s. net.—The author of this pamphlet may well be called the "Grand Old Man of Medicine" on account of the unfailing interest he displays in the progress and well-being of his profession, an interest which the passage of the years has in no whit diminished. When we consider that he was the contemporary and fellow-worker of Addison, and like that great physician bore a distinguished part in the unprecedented advance in medicine in the Victorian era, it serves to increase the pleasure with which we find him still defending the methods of scientific research which alone made that progress possible. The pamphlet is a convincing statement of the state of affairs which the most determined of antivivisection propagandists tacitly allow as being the normal relations between man and the lower animals, and from his statement of them the sanction for experimental research upon animals for the benefit of mankind stands irrefutably proved. We recommend these words of a scientist, a naturalist, and a true lover of animals to all interested on either side of the vivisection controversy; they were originally delivered at a church congress at Folkestone, and we trust that they have already borne good fruit amongst their clerical hearers.

The Microscope and How to Use it: a Handbook for Beginners. By T. CHARTERIS WHITE, M.R.C.S. Eng., L.D.S., F.R.M.S.; and A. MAURICE AMSLER, M.B., B.S.Lond. London: Robert Sutton. Pp. 160. Price 3s. net.—As an introduction to the study of microscopy, whether as a means of recreation or for more serious purposes, the beginner could hardly have a better book than the one under notice, which is now in its third edition and has been revised and enlarged. In it some extremely useful hints are given for the examination and capture of insects, and the suggestions with regard to the mounting of objects, the making of cells, and so on, are exactly what the beginner in microscopy requires. By following attentively the instructions the ingenious student will be able to devise means to overcome the various difficulties with which he is sure to meet if he pursues the study of microscopy with the enthusiasm which that study usually engenders. Another matter worthy of note is that the reader is not confused by too many formulæ. Diatom mounting is dealt with simply and practically, and there are valuable chapters on the delineation of objects and microphotography. This latter subject is one to which Mr. White has devoted special attention and the instruction which he gives is precise and practical. With regard to the delineation of objects, however, some account of the use of the stage micrometer ought to have been included, for no

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 7, 1907.

The Royal Commission on Human and Animal Tuberculosis.

Since the late Sir Michael Foster and his colleagues on the Royal Commission which is investigating the relation between human and animal tuberculosis made their well-known second report at the beginning of the present year certain developments of the question have arisen to which attention may usefully be drawn. In a leading article in The Lancet of Feb. 9th we pointed out that although the Commission continues to be engaged on further inquiries which are of the utmost importance, their second report is of itself sufficient to put beyond any doubt the serious danger of contracting tuberculosis to which the community is daily exposed by means of the milk of tuberculous cows; and we insisted that in this important respect the way is now clear for the adoption of practical preventive measures. The matter is one which requires Government action in the interests of the country as a whole. The fact that certain municipalities have obtained some powers under "tuberculous milk clauses" in local Acts to protect the inhabitants of their own districts, and that in the session just concluded the London County Council has obtained similar powers, in no way lessens the obligation which rests on the Government to take comprehensive action in the interest of the whole population. The degree of security which individual municipalities can obtain is at best small, and has to be secured by methods which are necessarily cumbrous and costly. When the public health department of London or Liverpool has succeeded in finding out that a cow is giving tuberculous milk at a farm 100 miles away, their powers only enable them to exclude the milk from the town concerned. The same milk thereupon may go elsewhere and imperil the lives of children in localities which are less fortunately situated.

The findings of the Royal Commission have caused a widespread desire for reform. During the past six months the agitation in favour of purer milk has grown considerably in force. The question has been raised by medical officers of health in almost every part of the country. It has been freely written about in the lay press and discussed at public meetings and sanitary conferences. Various other considerations besides the prevention of tuberculosis have been imported into these discussions, such as the necessity for "clean" milk as a means of lessening infantile mortality, the importance of securing more wholesome methods of storage and transit of milk, and the need for applying the Sale of Food and Drugs Acts to milk in such a way that the interests of the consumer receive as much consideration as the interests of the producer. From the statement lately on behalf of the Government in the House of Lords it would appear that the various questions of legislation and administration which have arisen in regard to the wholesomeness and quality of the milk-supply are to be considered during the recess by the Local Government Board in consultation with the Board of Agriculture. The fact that the principal medical officer of the Local Government Board, Mr. W. H. Power, is also chairman of the Royal Commission on Tuberculosis should be of great advantage to that department in devising administrative measures to deal with the milk question. Legislation will no doubt be needed and we trust that Mr. Burns, who has already given substantial proof of his desire to secure better protection to the public where dangerous foodstuffs are concerned, will see that the necessary measures are formulated and pressed upon Parliament without delay.

With one exception, all the promised supplementary volumes to the second report of the Royal Commission are now available. They leave no room for questioning the thoroughness and comprehensiveness of the work which has been undertaken during the past five years, under the Commission's direction, by the several investigators at the Commission's farms in Essex. The volumes relate to the following subjects: (1) The Pathogenic Effects of Bovine Viruses, by Dr. A. Stanley Griffith; (2) (published in two parts) the Pathogenic Effects of Human Viruses, by Dr. L. Cobbett; (3) (yet to be issued) on various comparative observations; and (4) Comparative Histological and Bacteriological Investigations, by Dr. Arthur Eastwood. To attack these five bulky Blue-books is a task from which the ordinary reader may well shrink, and in a brief series of articles, one of which appears in this issue, we have endeavoured to select some of the more salient observations in each. But we trust that no one will be deterred from obtaining and studying these volumes from consideration of their size. In each instance the material has been so skilfully arranged that the scheme and method of the volume can be apprehended *at once.* The principal observations and conclusions of each investigator are appropriately grouped, and tabular statements are given by means of which the reader who is in doubt regarding the evidence on which particular conclusions are based, or who wishes independently to study some special branch of the subject, can at once find his way to the facts. It may be noted that the Commission has left no uncertainty as to the meaning of negative results. In describing pathological appearances, for example, they are not content with such general phrases as "other organs normal;" the accounts given show in each instance what appearances were ascertained and what organs were examined. The volumes should find a place in every pathological library, and it is satisfactory to find their price moderate by comparison with some other Government publications which include many diagrams and illustrations.

Readers of the Commission's second report who also study these supplementary volumes can hardly fail to realise how many important questions connected with the etiology of human and animal tuberculosis have been opened up by these researches. These questions call for further investigation, either by the Royal Commission, if its members are able to continue for a sufficient period to give their ungrudging and unpaid assistance to the State, or directly branches is delivered daily except Fridays and Saturdays at 5.15 P.M. Classes are also held in otology, laryngology, ophthalmology, radiography, anatomy, nervous diseases, microscopy, urinary analysis, gynæcology, practical bacteriology, mental diseases, hygiene and public health, and operative surgery. Extra classes in any subject are formed to suit the convenience of practitioners unable to attend those already provided. Special tutorial classes are held for practitioners reading for the higher examinations. A complimentary ticket available for three successive days will be issued to any practitioner upon presentation of his visiting card. A monthly journal, the *Polyclinic*, recording the work done in the college, is issued free to subscribers and members. The annual subscription for medical practitioners of either sex, holding qualifications granted in any British dominion, is one guinea. Full information can be obtained from the medical superintendent at the college, 22, Chenies-street, Gower-street, W.C. The autumn session commences on Monday, Sept. 10th.

Charing Cross Hospital.—Classes for post-graduate study are held on each Tuesday throughout the sessions of the medical school at Charing Cross Hospital. The fee for each complete course is £1 1*s*. The first of the two winter courses this year will commence in October. Short courses of instruction in special subjects (otology, laryngology, &c.) will be arranged if a sufficient number of gentlemen give in their names as wishing to attend. Further information as to the dates and subjects can be obtained by communicating with the honorary secretary (Dr. Bosanquet) at the hospital.

The Hospitals of the Seamen's Society.—In connexion with these hospitals there are two post-graduate schools—viz., (*a*) the London School of Tropical Medicine; and (*b*) the London School of Clinical Medicine.

(*a*) *The London School of Tropical Medicine.*—The school buildings, laboratories, museum, library, &c., are within the grounds of the Branch Hospital Royal Victoria and Albert Dock (Station Connaught-road, Great Eastern Railway). Opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the service or going abroad. In the hospitals of the society are to be found cases of tropical diseases such as may be met with in actual practice in the tropics. There are three courses in the year, each lasting three months, beginning Oct. 1st, Jan. 15th, and May 1st respectively. The laboratory, museum, library, &c., are open daily and clinical instruction is given daily in the wards of the hospitals. The School Course is recognised by the University of Cambridge for their Diploma of Tropical Medicine and Hygiene. Classes are arranged for advanced Helminthology, Protozoology, and Entomology. The lecturers in the school are: Sir P. Manson, F.R.S., Dr. Andrew Duncan, Dr. L. Westenra Sambon, Dr. J. M. H. Macleod, Professor R. Tanner Hewlett, Mr. James Cantlie, Mr. E. Treacher Collins, Dr. F. M. Sandwith, Mr. Goadby, and Professor W. J. Simpson. The Director is Dr. C. W. Daniels. Certificates are granted after examination to those who complete a full course. Resident chambers are available for students, who must be qualified or in the *fifth* year of their medical studies. Prize: the Craggs prize of £50 is awarded yearly.

(*b*) *The London School of Clinical Medicine* (for qualified practitioners only).—The lecture rooms, pathological laboratories (two), museum, and operative surgery class-rooms, are in the *Dreadnought* Hospital at Greenwich, and the whole hospital of 250 beds with its Out-Patient Departments is open to students from 10 A.M. till 5 P.M. Medical, Surgical, and Special Department In-patient Cliniques are held upon every afternoon except Saturday by the senior members of the staff and operations are performed daily, whilst out-patients in the Medical, Surgical, and Special Departments are demonstrated by the assistant physicians and assistant surgeons daily in the forenoon. Practical classes are arranged three times a year in the following subjects: The Practice of Medicine; the Practice of Surgery; Diseases of the Eye; Diseases of the Throat, Nose, and Ear; Diseases of the Skin; Diseases of the Nervous System; Operative Surgery; Clinical Pathology, Microscopy, and Bacteriology; Mental Diseases; Radiography; Dental Surgery; the Administration of Anæsthetics; Hygiene and Public Health; Gynæcology; Surgical Diseases of Women; Surgical Diseases of Children; Medical Diseases of Women; Medical Diseases of Children; Applied Anatomy; and Midwifery. Three sessions of three months' duration are held in each year, beginning on Jan. 15th, May 1st, and Oct. 1st. Every variety of disease may be studied in the wards and out-patient rooms of the hospital, at the dispensaries, and at the affiliated hospitals. Male patients chiefly are received as in-patients by the Seamen's Society but arrangements have been entered into with the Royal Waterloo Hospital for the reception of graduates who desire instruction in diseases of women and children; with the Bethlem Hospital for those who require tuition in mental disease; and with the General Lying-in Hospital, York-road, for the prosecution of study in midwifery. These hospitals are situated on the south side of the river, are directly linked to the *Dreadnought* by both railway and tramway, and are affiliated to the London School of Clinical Medicine. The certificates of the School are recognised by the Admiralty, the War Office, and the University of London (for the higher degrees). The supply of material affords exceptional facilities for practical instruction in operative surgery and in pathology on the cadaver. The hospital also offers a wide field for the study of venereal diseases and there is a special department with open-air wards for the treatment of tuberculosis. The teaching staff is: Sir Dyce Duckworth, Dr. Frederick Taylor, Dr. J. Rose Bradford, F.R.S., Dr. R. Tanner Hewlett, Dr. Guthrie Rankin, Sir William H. Bennett, K.C.V.O., Mr. Albert Carless, Mr. William Turner, Mr. Lawrie H. McGavin, Mr. L. Vernon Gargill, Mr. Malcolm Morris, Dr. StClair Thomson, Dr. James Mackenzie Davidson, Dr. S. Russell Wells, Dr. A. Ernest Jones, Mr. Harold Burrows, Mr. E. Rock Carling, Mr. Stephen Mayou, Dr. Wilfrid Fox, Mr. A. Lawrence, Dr. Maynard Horne, Dr. Cecil Hughes, Dr. Vivian B. Orr, Dr. R. E. Delbruck. The extra-mural lecturers are: Dr. James Taylor, Dr. W. H. B. Stoddart, Dr. W. J. R. Simpson, Dr. James Cantlie, Dr. William J. Gow, Dr. Herbert Williamson, Mr. Russell Howard, Mr. Herbert S. Pendlebury, Dr. Alexander Haig, Dr. Robert O. Moon, Dr. Charles O. Hawthorne, Dr. Thomas D. Lister, Dr. William Radford Dakin, Dr. Robert Boxall, and Mr. W. Johnson Smith.

The prospectuses, syllabuses, and other particulars of both schools can be obtained on application to the Secretary, Seamen's Hospital, Greenwich, S.E., or from the Medical Superintendents at the Schools.

West London Post-Graduate College, West London Hospital.—The West London Post-Graduate College was started in 1895 and three years later its basis was enlarged by the provision for the post-graduates of lecture-, reading-, and waiting-rooms, &c., while owing to the continued growth of the college these were transferred in 1901 to a building especially constructed for the purpose. Over 1300 post-graduates have been enrolled since its establishment, the yearly entry being now about 200. The hospital, which contains 160 beds, is in the main Hammersmith-road, about three miles from Hyde Park Corner, and very accessible by omnibus, tram, or train. The physicians and surgeons attend daily at 2.30 P.M. Post-graduates accompany the staff and the junior staff on their visits to the wards. Instruction is given in the out-patient department daily at 2.15 P.M. by the assistant physicians and assistant surgeons. The out-patient department has recently been enlarged and there is now ample accommodation for post-graduates to see and examine the patients in all the special departments of the hospital. Clinical assistants for special work are appointed from among the post-graduates, and practical classes, limited in number, for instruction in special subjects, as well as in medicine and surgery generally, are held as required. Operations are performed daily at 2.30 P.M. Post-graduates are allowed to stand close to the table and can see the operations perfectly. The surgeons often avail themselves of the assistance of post-graduates at operations. Instruction is given in the administration of anæsthetics by the anæsthetists on the operating days and post-graduates are allowed to administer anæsthetics under their superintendence. Post-mortem examinations are performed at 12 noon, and demonstrations on recent pathological specimens are given on Mondays at 12 noon during each session in the pathological laboratory. Practical lectures and demonstrations are given each afternoon (except Saturdays), at 5 P.M., during the session. Included in this course are lectures by outside specialists on Mental Diseases and on Public Health, and in connexion with the former instruction is also given in certain asylums. The college is licensed for the teaching of operative surgery. The fee is £4 4*s*. each member in a class of four. The practice of the hospital is well adapted to the needs of medical officers of the Royal Navy and officers of the Royal year, p. 89. The serum is obtained from asses after they have been subjected to a combined active and passive immunising treatment—that is, to a simultaneous inoculation with serum and with virus. After many experiments on other animals Dr. SCLAVO found the ass to be the most suitable and his process was fully described in 1897. Dr. LEGGE, in the paper above referred to, said that Sclavo's serum had then been used in 158 out of 164 cases which had come to his knowledge, and that the mortality in these cases had been 6·09 per cent., as contrasted with 24 per cent. of all cases occurring in Italy, or with 26 per cent. in 211 cases in this country. Dr. IVO BANDI has since published the histories of two cases of great severity which recovered after injections of the serum; and Dr. G. SULLI, of Palermo, has reported a similar experience in the number for Jan. 20th last of the *Gazetta degli Ospedali e della Cliniche*. It would seem, indeed, as if the efficacy of the serum were fairly comparable, in anthrax, to that of antitoxin in diphtheria, an efficacy which Sir ALMROTH WRIGHT has told us recently is much in excess of the ordinary results of serum treatment. It seems evident, however, that, pending the attainment of some trustworthy and harmless method of disinfecting raw materials, an effort should be made to protect the workmen employed about such materials by immunising injections; and after the experience of PASTEUR in protecting sheep and cattle it is remarkable, not only that so little should have been even attempted in this direction, but also that the little in question should have been attempted in India. PASTEUR, it will be remembered, protected sheep and cattle by inoculation with anthrax cultures grown at from 42° to 43° C. and attenuated. In the years 1892 and 1893 he reduced the previous anthrax mortality among French cattle from 5 to 0·34 per cent. and that among French sheep from 10 to 0·94 per cent. Dr. LEGGE now quotes from a report by Dr. LINGARD, Imperial bacteriologist to the Government of India, a statement that a severe outbreak of anthrax having occurred among prisoners working in wool in the Bareilly jail the medical superintendent at his suggestion undertook to use anti-anthrax serum both to treat the persons affected and also to confer immunity upon those exposed to the contagium. Although the serum treatment of those affected was not employed with sufficient promptitude its effects appear to have been decidedly beneficial, for out of 60 men who had been in contact with the contaminated wool, and to each of whom it was thought desirable to administer five cubic centimetres of serum subcutaneously as a prophylactic, no untoward symptoms occurred in 59. 14 days after the injections the sixtieth man contracted the disease and recovered, all the 60 having in the interval been much exposed to danger, as they were employed in cleansing the woolsheds in which the infected material was stored. It would surely not be impossible for the Bradford board and Dr. EURICH to induce some of the more intelligent workmen of the district to submit to preventive inoculation, and thus to set an example which in time might be extensively or universally followed among those who are exposed to infection. It would also seem as if there were room for a very strong recommendation from the Home Office with regard to the kind of "serum" which should be used in the treatment of occurring cases, and with regard to the necessity for promptitude in its employment. The details given in the report appear to show that valuable time was lost in more than one instance, and they render it only too apparent that time thus lost is not easily regained.

* * *

The Council of Southend-on-Sea and their Medical Officer.

THE municipal council of Southend-on-Sea has just engaged in a conflict with the medical officer of health of the district, Dr. J. T. C. NASH, of such a nature that its issue may not impossibly exert an abiding influence upon the conditions of municipal sanitation. Dr. NASH, who is M.D. and C.M. of the University of Edinburgh and holds the D.P.H. of Cambridge, has been medical officer of health of Southend for more than six years, having been appointed and reappointed for a triennial period; and he has been eminently conspicuous for the thoroughness with which the duties of his office have been discharged, as well as for the amount of skill, care, and knowledge which he has brought to bear upon them. Southend is a large and growing health resort with a population of something like 60,000, this figure being based on the estimated residential population of over 50,000, which is swelled by a constant influx of trippers and tourists. Here we have an inevitable tendency towards the establishment and multiplication of influences injurious to health. Among these influences not the least has been the existence of oyster and cockle beds in situations not sufficiently protected against contamination; and these were said not only to have been causes of typhoid fever in Southend itself but also to have occasioned outbreaks in places where the molluscs had been sent as presents by visitors, or where those partaking of them on the spot had returned. There have also been transactions concerning the sale of food-stuffs and concerning the existence of premises unfit for their purposes, in connexion with which persons of local influence have not on all occasions set an entirely creditable example to their neighbours. The general result of the conditions has been that Dr. NASH, as an active and zealous officer, although his work has been fully appreciated by the right-minded, has incurred a good deal of ill-will in quarters in which the existence of such a feeling is the highest possible testimonial to his merits.

At the ordinary meeting of the town council on August 20th, the term of Dr. NASH'S appointment having expired on the preceding evening, a motion for its renewal had been placed as a matter of routine on the agenda, apparently with no expectation that it would be opposed. His enemies, however, had been on the alert and, possibly availing themselves of the circumstance that several of the members of the council were absent on their holidays or from other causes, one, Councillor WRIGHT, moved as an amendment that the reappointment should be for one year only and at a salary reduced from £600 to £500. This amendment was carried, and was afterwards carried as a substantive motion, nobody seeming to know that it was *ultra vires*. The council had a perfect right to re-elect Dr. NASH for the old period and on the old terms, but it blood, diphtheria, tuberculosis, agglutinins and agglutination methods, precipitins, and hæmolysins. If a large enough number of names are sent in a course in pharmacology (Dr. W. E. Dixon) and a series of lectures and demonstrations on protozoal diseases (Dr. G. H. F. Nuttall) can also be arranged. The pathological and pharmacological laboratories are open to advanced students and graduates. Applications for information should be made early in the year to Professor Sims Woodhead.

Leeds.—For the past two years a course of post-graduate demonstrations has been held by members of the staff of the Leeds Public Dispensary. The course has been well attended, but the desire being that the instruction should be eminently practical and demonstrative rather than didactic, the attendance has been fixed at a maximum of 20. On each occasion the number of applicants to attend the class has been in excess of this, and the class will in consequence of this encouragement be continued and developed. Very great facilities are afforded in the pathological and physiological departments for work in connexion with the D.P.H. diploma and for private research, and there are always some qualified men dissecting in the anatomy department. During the summer a class on applied anatomy is held by the professor of anatomy and this forms a useful means of qualified men keeping up a knowledge of anatomy.

Liverpool.—At the University of Liverpool the department of Bio-chemistry is devoted entirely to post-graduate teaching and research upon chemistry in relationship to biology and medicine. The laboratory is open daily for research, and courses of laboratory instruction in those parts of the subject most closely related to medical work are given for medical practitioners by arrangement with Professor B. Moore. A course of lectures and demonstrations in comparative bacteriology and parasitology is given during the autumn and Lent terms by Professor H. E. Annett, who also conducts a course of lectures and demonstrations in comparative pathology during the summer term. By special arrangement a practical course in clinical bacteriology and hæmatology is given twice weekly during the summer term by Dr. W. B. Warrington and Dr. E. E. Glynn. The Thompson Yates and the Johnston laboratories are open for post-graduate research in pathology and physiology during the winter and summer sessions under the supervision of Professor Sir Rubert Boyce and Professor C. S. Sherrington. A course of lectures in cytology is given in the summer and another in the winter by Mr. C. E. Walker. These are free to post-graduates. Courses on special subjects are given by other lecturers of the University during the summer session by arrangement with medical practitioners. At the Liverpool Royal Infirmary special arrangements exist whereby medical practitioners can keep in touch with the most recent methods adopted in hospital practice. Three courses annually are given in Tropical Medicine and Parasitology in the Liverpool School of Tropical Medicine in the University, and a Diploma in Tropical Medicine is granted.

Manchester.—The plan adopted a few years ago of having special courses of lectures on medicine and surgery for qualified medical men has since that time been considerably modified. Classes are now held and lectures given on various special subjects, as, e.g., diseases of the heart, diseases of the respiratory organs, of the kidney, and so on, and the same obtains as to surgical matters. These lectures are designed to meet the wants of senior students and practitioners. The public health department, presided over by Professor Delépine, is largely attended by medical men, as are also the lectures on bacteriology given in the College course by Dr. Sidebotham. There is no difficulty in Manchester in the way of any practitioner who wants to have his recollections revived or his knowledge enlarged and brought up to the present standard in accomplishing his wish.

Sheffield.—At the University of Sheffield post-graduate courses are held annually. The subjects vary from time to time and include bacteriology, physiology, applied anatomy, surgery, operative surgery, ophthalmic surgery, diseases of ear and throat, dermatology, &c.

Newcastle-upon-Tyne.—At the University of Durham courses of instruction are given in chemical and physical laboratory work and lectures are delivered on comparative pathology and practical bacteriology for the Diploma in Public Health and the Degree of Bachelor in Hygiene.

SCOTLAND.

Aberdeen.—Although there is no special provision at Aberdeen for post-graduate study such as exists in London, still there are some facilities for doing work of this nature at the University. There are fully equipped laboratories in anatomy, anthropometry, bacteriology, botany, chemistry, pharmacology, physics, physiology, public health, and zoology. Graduates or others desiring to engage in special study or research may be admitted by the Senatus to prosecute such study or research in any of the laboratories in accordance with certain provisions. Research students are exempted *from payment of laboratory fees but are required to matriculate* each year, paying the ordinary matriculation fee (£1 1*s.* for winter and summer; 10*s.* 6*d.* for summer). Forms of application for admission as research students may be had from the secretary of the Senatus. The fees are £3 3*s.* for six hours per week in winter or nine hours per week in summer, 10*s.* 6*d.* and 7*s.* being charged for every extra hour per week in winter and summer respectively. The fee for the Public Health Laboratory for six months is £6 6*s.*, and for the bacteriological laboratory for three months is £4 4*s.*, £3 3*s.*, and £1 11*s.* 6*d.* being respectively charged for a half course or any less time. At the Royal Lunatic Asylum, accommodating above 700 patients (fees, £2 2*s.* for three months), arrangements are made for extra teaching in the higher departments of medical psychology and cerebral pathology for graduates who desire it or wish to obtain the certificate of the Medico-Psychological Association of Great Britain and Ireland. Clinical work may be done at the following places:—(General Hospital): Aberdeen Royal Infirmary (accommodating 200 patients, perpetual ticket £6, or first year £3 10*s.* and second year £3, thereafter free); Sick Children's Hospital (75 patients; first year £2 2*s.*, then £1 1*s.*); City (Fever) Hospital (100 beds; £1 1*s.* for three months); General Dispensary and Lying-in and Vaccine Institution (10,000 out-patients per annum; perpetual fee, £3 3*s.*); and Ophthalmic Institution (16,000 patients per annum, fee £1 1*s.*). During the summer session (April to June) special classes, each costing £2 2*s.*, are held at the Royal Infirmary, the subjects being Diseases of the Skin, Medical Electricity, Dental Surgery, Anæsthetics, Ophthalmology, and Gynæcology. Lectures on Diseases of the Ear and Throat are given at the dispensary and on Tropical Medicine at Marischal College. In Tropical Medicine the course embraces attendance on (1) the ordinary course of Bacteriology (Systematic and Practical) as required for M.B., Ch.B., or D P H.; and (2) special course of 25 lectures on Tropical Medicine. A detailed account it given of malarial fevers, including hæmoglobinuric fever, yellow fever, plague, dengue, Malta fever, heat stroke, and other fevers found in the tropics, beri-beri, cholera, dysentery, sprue, tropical liver diseases, leprosy, yaws, oriental sore, filariasis, and parasites generally, and mycetoma.

Edinburgh.—The arrangements for this course have been completed. The course begins on Monday, Sept. 2nd, and lasts until Saturday, Sept. 28th. The composite fee for the four weeks' course is £5 5*s.*, or £3 3*s.* for either the first or second fortnight. A special additional fee of £1 1*s.* is charged for the following classes which will be limited in numbers: Diseases of the Blood (elementary and advanced); Bacteriology (elementary and advanced); Gastric Methods; Pathological Methods; Ophthalmoscopy; Errors of Refraction; Diseases of the Ear, Throat, and Nose; and X Ray and Electrical Work. Places in the limited classes will be allocated in the order in which the names are received. The other courses of instruction which will be supplied are: Applied Anatomy, Anæsthetics, Diseases of Children, Dietetics, Diseases of the Heart, Infant Feeding, Infectious Diseases, Neurology, Diseases of the Skin, Surgical Pathology, Surgery of the Urinary Tract, Tropical Diseases, Examination of the Urine, Venereal Diseases; while in addition Medical and Surgical Clinics will be given in the wards and some special lectures will be delivered. In addition to the foregoing an Operative Surgery Class has been arranged for, the fee for which is £5 5*s.* in addition to the composite fee for the course. The detailed prospectus of the course can be obtained by applying to the Secretary, Medical Faculty Office, University New Buildings, Edinburgh.

Glasgow.—At Glasgow the possibilities for post-graduate work are considerable and in almost every department graduates have opportunities for acquiring more special knowledge or carrying on original work. In pathology, courses bitter enemy of the medical profession we venture to think, would be found to accuse the members of the medical profession of a tendency to discourage any measure intended to promote the saving of human lives, and Mr. Burns, who has commented on the profession's action in this matter adversely, has not understood the point at issue. The earlier notification of births will do much towards the saving of life and the lowering of the present high infantile mortality, but we protest against the obligation of notification under the pain of a penalty being thrown on the medical man, as it undoubtedly will be in a large majority of the cases. That a medical man should be called upon to perform, under pain of a penalty, what is essentially a civil duty and above all a duty which should be incumbent especially on the parents, is a condition against which we consider the profession is quite justified in protesting. That the State should demand from a medical man what is a public duty without providing any adequate remuneration for such a service is hardly equitable. That medical men would undertake such a duty voluntarily we believe, but that they should be required to do this under compulsion is a different matter. Nor, indeed, is this the only objection to the Act as it relates to the medical profession. Cases may well occur from time to time in which the professional relationship between the medical man and his patient may well render him loth to send such a notification even if he does not feel it his duty actually to keep silence. The amendment which was moved by Lord Robert Cecil in unfortunate terms to relieve medical men from the obligation to notify under the Act would have been passed if its supporters had made the professional view clear.

THE DUTY OF GIVING PUBLIC MEDICAL ADVICE.

IT is a penalty of belonging to the medical profession that each member adopts responsibilities of a gravity far exceeding those of most other walks in life. We individually and collectively owe duties not only to our patients but also to the world at large. Directly or indirectly we are the arbiters of the health of the people, and we are responsible for their education in those matters of personal and public hygiene upon which their health depends. It is true that much has already been done and is being done by the profession in this respect, but it cannot be denied that much yet remains to be done, more particularly in educating the public to saner views upon the treatment of minor ailments, many of them the result of the strain of modern civilised life. We are too prone to shirk this responsibility and to leave the laity, ignorant in these matters, to obtain instruction from dubious sources. Hence the prevalence of quackery in its protean manifestations, many of them insidious in their quasi-religious features, others openly unashamed, and all flourishing like a green bay tree. It may be some consolation to us to condemn these things in the medical press and elsewhere when opportunity arises, but permanent benefit can be assured only by educating the public to realise for themselves the fallacies and absurdities of the claims of charlatans. We may agree with Carlyle that the population is composed chiefly of fools, but if so it is the duty and the privilege of our superior knowledge to make every effort to relieve their ignorance. That many are willing and anxious to learn is shown by the avidity with which they absorb the tainted medical pabulum provided for their gratification by the lay press. Like the average English schoolboy who acquires his knowledge of sexual physiology from obscene sources, often to his lifelong regret, the public learn their pseudo-medicine from catchpenny paragraphs and old wives' tales Is it any wonder that the vendor of preposterous nostrums flourishes whilst the general practitioner starves or is ill-requited for his services? It is difficult to suggest remedies for this state of affairs. Those best qualified to deal with the matter shrink from the publicity involved, dreading above all things the stigma of self-advertisement even if they are willing to devote the necessary time without hope of remuneration. It is true that occasionally the acknowledged leaders in the profession are heard upon the philanthropic platform on questions of school hygiene, and so on, and sometimes their opinions, veritable or alleged, find their way into the lay press. Rarely, indeed, is an accurate and sensible book or pamphlet written without *arrière pensée* purely for the instruction of the laity. A collection of such papers on "Eye Strain and Eyesight" has recently been published by Messrs. J. and A. Churchill, written by Dr. J. Grimshaw,[1] a general practitioner. The material is excellent on the whole, but while the author is inclined to inveigh against the specialist, some minor errors would not have crept in if the articles had been written by an ophthalmologist. Nevertheless, we cannot but think that such a book will do good, and we hope that the general public will read it, and mark, learn, and inwardly digest its contents. The fact, moreover, that the author is not a specialist has its significance; the censorious cannot suggest that the work was published with self-interested motives. An ophthalmic surgeon might have improved the text in a few details, but he would have been compelled to withhold from the book the authority of his name.

THE CIGARETTE HABIT.

THE smoking of cigarettes is increasing and the reasons why this form of indulgence in tobacco is outstripping the use of pipe or cigar are interesting to the medical man. A really good cigar is expensive and to be appreciated it must be smoked at leisure. However good the cigar may be the smoke is strong, heavy, and lingering compared with that of the cigarette. Medical men have not much time and often not much money to spare, while the less permanent the odour of their tobacco is the more convenient for them. The pipe, of course, can be taken up at any time, but the use of the pipe involves some preparation and entails also a larger armamentarium. The pipe-smoker must carry with him besides his pipe his tobacco in a pouch. Before he can smoke the pipe must be carefully filled and even then something may go wrong with the combustion, smouldering may proceed irregularly or some difficulty may be found in keeping the "fill" well alight. All these sources of trouble are avoided in the cigarette. The cigarette is at once ready to smoke, it only requires lighting, and, as a rule, once alight it burns regularly. The smoker of the cigarette reaches his aim more quickly and with less trouble than does the smoker of the pipe, and if smoking is to be a soothing habit there must be nothing mentally irritating connected with it. It is thus that the cigarette habit is encouraged and eventually established among medical men just as much as among the public, and once that is so the habit becomes confirmed and both cigar and pipe are neglected. The worst of the cigarette habit is that the smoker consumes more tobacco in that form than he would in any other. The cigar and pipe soon satisfy the tobacco craving, the cigarette smoker is rarely warned in time of his excess. The cigarette appears as a mild form of smoking of which the smoker never tires and cigarette replaces cigarette with practically little intermission throughout the whole day. Few can deny that such a practice is very injurious to the health and the slaves to it find it hard to break

THE
BRITISH MEDICAL ASSOCIATION.

MEETING AT EXETER.

THE SECTIONS.

PATHOLOGY.

THURSDAY, AUGUST 1ST.

THE proceedings opened with a communication on

Experimental Chemotherapy in Trypanosome Infections

by Dr. CARL H. BROWNING (Glasgow), who stated that the greatest promise of successfully combating diseases due to trypanosomes seemed to lie in specific chemotherapy, hence the value of experimental investigation on this subject. He referred to the results which he had obtained in the laboratory of Professor Ehrlich at Frankfort-on-the-Main. The scope of his very extended series of experiments was considerable and embraced the treatment of highly virulent nagana infections in mice by means of the acetyl and paroxybenzaldehyde derivatives of para-amidophenylarsenic acid (of which acid, as had been shown by Ehrlich and Bertheim, atoxyl was the sodium salt), and in this part of the investigation a remarkably high percentage of permanent cures was ultimately obtained. Dr. Browning proceeded to discuss an extremely interesting phase of his experimental work, the gradual development, during the administration of these drugs, of chemo-resistant strains of trypanosomes which are no longer susceptible to the influence of the drugs employed. He then showed amongst other further properties of these chemo-resistant strains that the resistance to any one or more specific drugs was transmitted almost without diminution to succeeding generations of parasites, but that trypanosomes which had been immunised, so to speak, to one *group* of chemo-therapeutic agents remained susceptible to other groups; in other words, each group of chemo-therapeutic agents combined with different chemo-receptors of the protoplasm of the parasitic trypanosomes, thereby establishing the reason for the efficiency and the efficacy of the combined treatment by a variety of groups, as compared with the results obtained when only one group was exhibited. These observations were received with great interest by the members present, and in reply to a query from the PRESIDENT (Professor R. MUIR of Glasgow) Dr. Browning stated that his opinion was that the resistance exhibited by the trypanosomes to drug groups was a natural, though but slightly marked, characteristic which was merely accentuated by certain methods of treatment.

Dr. H. BAYON (London) read a paper on

Endotheliomata and Peritheliomata and their Position in Oncology.

He said that the conclusions drawn from the study of endothelial and peritheliomatic growths were that the name "endotheliomata" ought to be exclusively reserved for those growths which really showed similarity in disposition, position, and general morphology to the genuine endothelium which was the lining membrane of blood-vessels and lymphatics, and that from a purely *morphological* standpoint it was inadmissible to make use of the expression "peritheliomata" to designate growths of a peculiar class. The simple morphological expression "perithelioma" (in order to mark the principal peculiarity in the appearance of the growth) was alone requisite, because, with the single exception of growths of the carotid body, a somewhat indefinite cellular element was the subject of investigation. Among the growths which might be called of a definite cell type—that is, growths which showed the smallest degree of anaplasia—the hypernephroma or growth peculiar to the adrenal body must be accorded the most prominent place. Growths which appeared to originate from the lining membrane of the pleural, the pericardial, or the peritoneal cavity could with exactitude be considered as endotheliomata, but required to be classed by themselves. Similar treatment should be accorded to growths peculiar to the hypophysis, thyroid, so-called parathyroid glands, and adrenal bodies. Dr. Bayon concluded that though his attitude remained unchanged so far as concerned the opinion that carcinoma was carcinoma from the very earliest beginning, he could not maintain a similar radical [illegible]oint regarding sarcoma.

Dr. B. H. SPILSBURY (London) regarded peri- and endotheliomata as essentially similar histologically. The layer of structureless hyaline material which lay between the tumour cells and the endothelium lining the vessel in peritheliomata, and which alone served to distinguish them from endotheliomata, varied considerably in thickness and often could only be distinguished with difficulty. Endotheliomata and peritheliomata were probably closely related to sarcomata, into which they exhibited a marked tendency to merge, and this change was well illustrated by the development of congenital pigmented nævoid tissue in the skin into melanotic sarcoma.

Dr. BAYON in his reply disagreed *in toto* with these views.

The previously arranged discussion on

Phagocytosis and Bactericidal Action

was then introduced by Dr. GEORGE DEAN (London), who, having first alluded to the great importance of Metchnikoff's theory of phagocytosis, remarked that even while upholding the cell as the essential factor, Metchnikoff and his pupils could not long overlook the part played by the body fluids in the processes of protection. The work of Nuttall, Pfeiffer, and others showed that the blood serum alone in the absence of cells had powerful bactericidal properties. It soon appeared, however, that bactericidal effects of serum due to bacteriolytic action could not be demonstrated in the case of all organisms—e.g., staphylococcus and streptococcus. According to Metchnikoff this bactericidal action did not play an important part in the living body under normal conditions, and the bactericidal substance had its origin in the phagocyte and was set free by its death during the process of clotting or, in the case of the living animal, when phagolysis was produced by an excessive dose of bacilli injected experimentally. Bacteriolysis, therefore, was a secondary phenomena to phagolysis. On the other hand, in the case of immune animals there were present in the blood substances which played an important function in aiding phagocytosis. These latter bodies were thermostable, unlike the substance previously referred to, the cytase or complement, readily destroyed by a temperature of 56° C. Two forms of activity had been attributed by Metchnikoff and his pupils to these thermostable bodies: (1) a *stimulin* action; and (2) a *fixative* action. When a highly virulent organism was injected into a normal animal the leucocytes did not show any great disposition to attack the invader. The virulent organism tended to repel, or at least not to attract, the phagocyte. In an immunised animal, on the other hand, no sooner did the virulent organism find an entrance into the body than the leucocytes crowded to the site of infection, surrounded the invaders, and if the immunity was sufficient englobed and destroyed the enemy. Dr. Dean described experiments proving that this property was due to something in the plasma or serum and not to properties of the leucocytes acquired by education or otherwise. Substances which heightened the activity of the leucocytes Metchnikoff had designated "stimulins." In the second view the serum was conceived as acting primarily not on the leucocyte but rather on the microbe, on which a change was produced so that it no longer repelled but rather attracted the phagocyte; in other words, its negative chemiotaxis was converted into a positive chemiotaxis. Owing to the impossibility of detailing even the chief of the earlier contributions on the subject, the speaker referred the members of the section to a brief *résumé* which he had already published in a former paper, and continued that fresh interest in these questions had been awakened especially in this country by the work of Wright and Douglas, who had made a number of observations emphasising the importance of the serum in the mechanism of phagocytosis, and showing for the first time in an unequivocal manner the fact that normal serum as compared with other fluids such as normal salt solution had a powerful action in preparing the microbes for phagocytosis in cases where no bacteriolytic or bactericidal action was apparent. The substance in serum which had this action was found to be thermolabile and was designated by them "opsonin." Dr. Dean then proceeded to review the recent work on these lines, including its clinical application to vaccination for furunculosis, tuberculosis, &c., and detailed a number of his own experiments bearing on the subject. The bulk of the evidence as sifted from the literature and deduced from his own experiments along with those of others, drove him to the conclusion that *opsonin* was not a new substance having a separate activity. The opsoninising action was due, he

Journal of the American Medical Association, the worst flaws in the system of medical education in the United States are the generally prevailing low standards of preliminary education and the down-grade competition of bogus systems of medical education. "It is," says our excellent contemporary, "as much the duty of the medical profession to demand laws protecting the public from the ignorant and poorly prepared physicians which are being turned out each year by the number of low grade institutions which are parading as medical colleges as it is for them to decry the adulteration of foods and the designs of advertising quacks. To fulfil that duty requires that a public demand be created for laws which will insure the adoption and enforcement of higher standards." On the whole it would appear that a decided advance has been made in medical education in the United States during the past few years. An immense amount of money has been forthcoming for purposes of research and for erecting hospitals and other buildings connected with medicine. It is a most hopeful sign, too, that during the past year no less than 40 medical colleges have voluntarily raised the standard of entrance requirements, while three State examining boards have taken similar action. It may be stated that there are in the United States very nearly 130,000 medical men. The following ten States have the largest number of medical men in proportion to their population: District of Columbia, 1 to 258; Oklahoma, 1 to 284; Colorado, 1 to 351; California, 1 to 388; Vermont, 1 to 510; Washington, 1 to 516; Indiana, 1 to 519; Illinois, 1 to 521; Missouri, 1 to 531; and Ohio, 1 to 544. North and South Carolina and Minnesota have the least number of medical men in proportion to their population. Criticism from outside sources is not easily borne by those countries against which it is directed, and we are glad to find ourselves recording the views of Americans. In the case of medical education in the United States it seems that the medical profession as a whole and all the responsible medical papers are agreed that the standards are too low. Some of the States have a very good system of medical education but other States are very backward, and while there are medical schools in America which are equal to any in the world there are others in which the education given is almost farcical. In a few cities the multiplication of medical schools is carried to an absurd extent, as in Chicago and in St. Louis. All who have considered these points admit that an equally high standard of medical education in all the States of the country would be the only complete remedy, but it is clear that such a remedy is not yet attainable.

THE MEDICAL EXPLORER.

ZONE after zone in Central Africa is in course of annexation under the civilising imperialism of Great Britain, the latest being that just south of Lake Bangweolo, now occupied by the Livingstonia Mission on the invitation of the administrator of N.E. Rhodesia. An appeal in the February of last year to the United Free Church of Scotland for funds required for the new station met with the substantial response of £3000 and in the October following the mission work was started under Mr. Malcolm Moffat (grandson of the well-known Dr. Moffat and nephew of Dr. Livingstone), with Dr. Alexander Brown, an Aberdeen graduate, as his coadjutor. Having reached Chitambo, the scene of their labours, in May last, they settled provisionally at Serenje, the Government station, and in June made a pilgrimage to the monument erected on the spot where, on Mayday, 1873, was laid to rest the mortal part of David Livingstone. There they had an interview with the local chief, Chitambo by name, who narrated what he had heard from his father of the last hours of the "Engelesa" (Englishman) as the great medical explorer was called, details too extended for citation here, but redolent of the love and veneration he had inspired among the native tribes. "He was sick," said Chitambo; "he was here just one day and another day. His boys built him a 'msasa' (booth or hut) under the 'mupundu' tree and it was there that he died. His men took his body; they buried the heart and other parts; but his body they kept. They buried them under the mupundu tree; the body they dried in the sun. They stayed three moons drying the body; and the old Chitambo called the people from all the country round and they brought forth the drums, and they wailed the Engelesa. ...... Three months his men stayed in the village and they dried his body and put it in a box, and they tied it round and round, and Chitambo said, 'Engelesa has died here; it is his country now.' Then Engelesa's men brought forth much cloth, and gave it to the people, and they went away with the body to the north." Mr. Moffat, from whose graphic letter this narrative, quite Hebrew in its simplicity and power, is taken, has more to tell us of the reverential love in which Livingstone's memory is cherished in those regions; as, for instance, how the present Chitambo added: "I was a young boy when the old men brought me to the tree and told me of 'Engelesa,' and they said, when the white people came, take them to this tree and tell them about Engelesa." Livingstone's conquests were more than those of science; they were conquests of humanity. "This is his country now," said the old Chitambo who witnessed his death and burial. It is indeed "his country"—a country which, like its first explorer and occupant, knows no distinctions of race or creed or colour, but belongs to the ever-extending area of liberty and enlightenment whose pioneers, from the Portuguese missionaries downwards, have made the healing art a first weapon of conquest and the arts of peace a second.

INTESTINAL OBSTRUCTION.

THE *Johns Hopkins Hospital Bulletin* for August contains an important article on intestinal obstruction by Dr. Joseph C. Bloodgood, the result of a careful clinical and pathological summarising of the experience of Dr. Halsted's clinic. Two forms of obstruction are recognised—strangulation ileus and obturation ileus. In strangulation ileus, in addition to obstruction to the lumen of the intestine there is also interference with the mesenteric blood-supply; in obturation ileus there is no interference. In obturation ileus the period of survival from the onset of obstruction to operation is longer than in strangulation ileus, but in both forms early operation gives the best results. Dr. Bloodgood insists that intestinal obstruction from its onset should be looked upon as a surgical condition and that no conservative treatment should be adopted except washing out of the stomach and high rectal enemata. These should be used only in the early hours and if relief is not immediate laparotomy should be performed. All food, liquid or solid, and cathartics by the mouth are contra-indicated from the onset. Morphine should not be given unless operation has been decided upon. These rules, which are now generally taught, simple as they are, are not always followed in the cases of patients admitted into hospital. Too often drastic purgatives are given and symptoms are masked by opium. In strangulation ileus it is interference with the blood-supply that causes the acute symptoms of onset—intense pain, peritoneal shock, and primary reflex vomiting. Secondary vomiting, fæcal in character, and distension are due to the obstruction of the lumen of the intestine and are late symptoms which should not be waited for in order to make the diagnosis. As shown by Lennander[1] the intestine is insensitive and the pain of conjunction with Dr. James Miller. He said that in considering the phenomenon of the negative phase three explanations suggested themselves—viz., firstly, for the moment there might be a diminished output of opsonic substance; secondly, an undiminished output might be associated with an increased consumption due to more active phagocytosis; and thirdly, the opsonic substance might be eliminated by the excretory organs. The results of his experiments, so far as they related to patients suffering from pulmonary tuberculosis, showed that tuberculo-opsonic substances were eliminated in the urine in amounts capable of estimation; that the amount present in the urine of an inoculated person is for the most part less than that found in the same person's blood; that in fully 40 per cent. of the cases in which systematic observations were made during the negative phase the amount of opsonin present in the urine varied inversely as the amount present in the blood; and, finally, that tuberculo-opsonic substances were eliminated in the sweat. The obvious conclusion suggested by these results was that the fall in the index recording the amount of opsonic substances in the blood was due to an increased activity on the part of the various excretory organs in removing these substances from the blood. One practical outcome of this work related to the treatment of the "sweating" of pulmonary tuberculosis which Dr. Lawson suggested should no longer be allowed to go on unchecked, but which should be controlled, as it used to be some years ago, by the exhibition of atropin, &c.

---

[1] THE LANCET, August 17th, 1907, p. 465.

After some remarks by Dr. L. C. PEEL RITCHIE (Edinburgh),

Dr. F. G. BUSHNELL (Brighton) communicated some observations on

Phagocytosis in Myelocythæmia.

He stated that he had been attempting to determine the essential features of the rôle played by the leucocytes in the phagocytosis of bacteria. His experiments showed that there was a distinct and practically constant diminution of the power of phagocytosis of the patient's leucocytes from a patient suffering from myelocythæmia when estimated under comparable conditions to those of several workers in the Ralli Memorial Laboratory, and myelocytes had a still lower phagocytic power. He concluded that leucocytes differed in their phagocytic power in a functional sense.

Professor J. M. BEATTIE (Sheffield) next discussed

The Source of Antibacterial Substances in the Blood.

Referring to the presence of substances which were injurious to bacteria in the inflammatory exudates met with in the peritoneal cavity and the coexistent increase in polymorphonuclear leucocytes in the same situation he considered that there was no proof of such a close correlation of these factors as would suggest that the anti-substances were the products of the leucocytes. On the contrary, certain reactions pointed to the mononuclear cells—the endothelial cells of the omentum, &c.—as being the ultimate source of these substances. Further, he pointed out, phagocytosis was much more active in "citrated" blood 12 hours after its removal from the body than it was at two hours, greater still at 24 hours, and asked where, then, did that substance which assisted phagocytosis arise? The only conclusion he could offer was that it was derived from the cells, either by secretion or by phagolysis, which latter, it should be remembered, was diminished only and not by any means avoided entirely by the process of citration.

FRIDAY, AUGUST 2ND.

There being no pre-arranged subject for the morning's discussion, the attention of the section was directed to the reception of several highly interesting communications. The first of these was a paper on

The Relations between the Thyroid and the Parathyroid Glands,

by Dr. DAVID FORSYTH (London) who, after detailing the history of the study of the parathyroid glands, said that the investigations on which the present paper was based began with a series of operations on rabbits and cats. This line of research, however, was abandoned as the fallacies of the operation were found to be great. No conclusive data were available as to the number of parathyroids or their anatomical positions. Further, it was found to be a matter of great difficulty to identify these structures on the operation table from accessory thyroids, lymphatic glands, or thymic residues. A detailed investigation was therefore made of the glands in man and in more than 70 different species of animals (mammals and birds). As a result it was discovered that the parathyroids normally secreted a colloid material resembling thyroid colloid both physically and microchemically. Histological examination of the thyroid and parathyroid glands showed that while there was, as a rule, no difficulty in distinguishing the two structures, not a few instances were met with where the thyroid possessed in part or wholly the features of a parathyroid, and intermediate stages between the two bodies were comparatively common. Dr. Forsyth gave examples of several animals possessing thyroids with parathyroid characters, which pointed strongly to the identity of the two organs.

Immediately following the reading of his paper Dr. FORSYTH demonstrated a striking and convincing series of lantern slides prepared from sections of the various structures he had already referred to, showing the gradual transition from the vesicular formation of the thyroid to the glandular structure without colloid-filled vesicles of the parathyroid.

In the discussion which ensued Dr. BATON held that Dr. Forsyth's conclusions were not supported by the evidence of clinical observations and quoted five cases of congenital absence of the thyroid where the parathyroids had certainly not assumed the functions of the missing gland as the patients all exhibited the typical symptoms of cretinism.

The PRESIDENT of the section referred to the severe and serious immediate results of the experimental removal of the parathyroids as contrasted with the comparatively trivial symptoms following experimental thyroidectomy as militating against identity of function of the two structures.

Dr. FORSYTH, in a brief reply, reminded the members of the section of the difficulties attending removal of the parathyroid and attributed the severe effects following parathyroidectomy to *injury* of the thyroid (in which gland the parathyroid was imbedded) during the operation.

Dr. A. R. FERGUSON (Cairo) then gave an exhaustive lantern demonstration of

Lesions produced by Bilharzia in the Genito-Urinary Tract,

which was arranged in two parts. The first, comprising some 19 slides, illustrated the naked-eye changes resulting in the ureter (five slides), bladder (seven slides), liver (one slide), and colon (six slides) from invasion of the tissues by the ova of the parasite and the inflammatory response on the part of the tissues affected, in the case of the bladder and the colon, to the secondary septic infection of the ulcerated mucosæ by bacteria. The second part of the demonstration illustrated the histology of the earlier stages of bilharzia infection of the ureter (three slides) and of the bladder (five slides). Particularly interesting were those longitudinal sections of ureter showing the adult sexually mature worms *in situ* in the veins, the male inclosed in the gynæcophoric canal of the female, and illustrating the progress of the worms towards the lumen of the ureter.

Next followed a lantern demonstration of microscopical preparations and schematic drawings upon which were based a somewhat remarkable

Account of the Life History and Development of Spirochætæ,

by Dr. ALEXANDER MCLENNAN (Glasgow). The series included photographs of the spirochæta of yaws and of the spirochæta refringens showing what was stated to be spore formation. Many of the contentions put forward by Dr. McLennan and the interpretations which he placed upon many of his observations appeared alike open to question.

Dr. MCLENNAN then read a paper on

The Place the Spirochæta Pallida occupies in the Diagnosis of Syphilis,

in which he stated that the recognition of the spirochæta pallida was considered to amount to a diagnosis of syphilis. The discrepancy between the intensity of the disease and the numbers of the spirochætæ was held to be due to the probability of the protozoa causing syphilis assuming forms other than the spirochæta type at some stages of their life cycle. The methods available were by examination of a smear, either in the fresh state or after staining, and the examination of sections after the tissue had been treated by Levaditi's method. The presence of a single typical spirochæta in the stained smear went a long way towards making a diagnosis. It was considered that the recognition of the pallida was the difficulty, and in the living state it was not possible to differentiate the pallida from certain types of the refringens. If the presence of the may occur, for instance, by a person making contact simultaneously with two live conductors at different pressures, but more usually they result from the victim merely touching one conductor whilst being in contact with the ground. Momentary contact may not produce a serious shock, but a person who happens to grasp the conductor may be quite unable to release his hold and the shock is prolonged until assistance comes. In such circumstances a shock may prove fatal in a few seconds. The dividing line between conditions which on the one hand will render the shock trifling and on the other fatal is so narrow that it is necessary to provide that no shock will be received at all. The regulations are subject to further consideration and for the most part provide for efficient insulation and for the fencing off of "live" wires, terminals, switchboards, and so forth.

BRONCHIECTASIS ASSOCIATED WITH THE INFLUENZA BACILLUS.

The causal relation of the influenza bacillus to certain chronic pulmonary affections is not sufficiently recognised. In 1903 Dr. Lord of Boston isolated the influenza bacillus in a large number of cases of subacute and chronic "cough." In 1905 Dr. Boggs, house physician to Professor William Osler at the Johns Hopkins Hospital, reported six cases (in two of which there was a necropsy) which ran a course like that of chronic pulmonary tuberculosis, but the repeated examination of the sputum showed absence of the tubercle bacillus and the presence in large numbers of the influenza bacillus. In the *Montreal Medical Journal* for August Dr. E. T. F. Richards and Dr. F. B. Gurd have reported the two following cases. A Russian, aged 45 years, was admitted into the Montreal General Hospital complaining of pain in the left side and epigastrium, cough, expectoration, weakness, and loss of appetite. These symptoms were of some weeks' duration. On admission he was found to be poorly nourished. The skin was moist and he perspired frequently. There was severe cough with profuse, fœtid, yellowish-green, watery, purulent sputum. The cough was most marked in the morning and upon change of position, especially when he turned from his back to his right side. The chest was very emphysematous. Over the left lung posteriorly from the fifth rib downwards the percussion note was impaired and metallic blowing breathing, accompanied by loud blowing moist râles, was heard. Throughout both lungs the breathing was very harsh and there were numerous loud moist râles. At times the blowing quality of the breathing over the left lung was absent and was replaced by distant breath sounds. After violent attacks of coughing and expectoration the blowing breathing became more distinct. Repeated examination of the sputum showed no tubercle bacilli. The patient gradually failed and died, extremely emaciated, six weeks after the beginning of the illness. The necropsy showed firm adhesions over the posterior and external surface of the left lung and thickening of the pleura on the posterior surface. On section the lung tissue was airless and friable. The cut surface was of a reddish-grey colour, studded with small greyish-white nodules which were surrounded by a zone of hyperæmia. Many of the nodules had broken down into small abscesses. In the posterior part of the lower lobe, just above the root of the lung, were several small irregular cavities communicating with one another and with the large bronchi. These cavities were found to be sacculated dilatations of the bronchi, and they communicated with smaller cavities in the upper lobe. The posterior half of the right lung was consolidated. The surface was studded with innumerable small irregular nodules varying from three to six millimetres in diameter and surrounded by a wide dark red zone. Many of the larger nodules were broken down into abscesses. Examination of the lungs for the tubercle bacillus was negative but the bacillus influenzæ was found. Other organisms—staphylococcus aureus and albus, streptococcus, pneumococcus, and the micrococcu catarrhalis—were also found. Microscopic examinatio showed no evidence of tuberculosis but the characterist lesions of broncho-pneumonia and miliary abscesses. In th second case a poorly nourished man, aged 52 years, cam under observation. He had suffered from cough and feve for eight months. The lungs showed signs of consolida tion and cavity formation. There was severe cough, espe cially on change of position. The sputum was fœtid an nummular, the small masses being suspended in watery pu Repeated examination showed absence of the tubercle an presence of the influenza bacillus. There was dulnes from the fifth dorsal spine and seventh rib in th posterior scapular line to the base. Over this area breat sounds were diminished and accompanied by numerous lou moist râles. That the influenza bacillus was the cause of th lesions in those cases cannot be stated definitely. How ever, its presence in large numbers in chronic pulmonar conditions is usually taken as suggestive of its being th primary infecting organism. The course of these cases an of those previously recorded in which the influenza bacill was found is in many respects the same as that of chron pulmonary tuberculosis. There is usually much fœtid sputu hæmoptysis is not uncommon, and there may be a history chills and sweats, with progressive emaciation. The physic signs are those of acute bronchitis with cavity formation an consolidation.

A TUBERCULOSIS EXHIBITION.

We congratulate the Women's National Health Associati of Ireland, established in March last by Her Excellency t Countess of Aberdeen, who is the first President of t society, on the very practical step it has taken in foundi the Tuberculosis Exhibition referred to in the letter from o Irish correspondent. The object of such an exhibition in t present universal campaign against tuberculosis is to spre abroad among the people much-needed information in ref ence to the means for preventing, as well as the measures f securing the arrest of, the disease, especially in its early stag The exhibition, through its various sections, aims at educati the people, by objective teaching and demonstrations, to the prevalence, distribution, varieties (both surgical a medical), occurrence in men and animals, causes, cost, p vention, and cure of tuberculosis. By means of mode specimens (both human and animal), photographs, char diagrams, appliances, and so on, the main facts in regard the disease, its prevention and cure, will be taught in a w that it is hoped will be vastly superior to leaflets, papers, ordinary lectures. The plan has been adopted in Germa but it has been specially successful in America, wh apparently the first exhibition of this kind was held Baltimore in 1904, under the auspices of the Maryla Public Health Association. In the next year, 1905, tuberculosis exhibition was organised by the Natio Association for the Study and Prevention of Tuberculo and by the Committee for the Prevention of Tuberculosis the Charity Organisation Society of New York. During t last two years the Tuberculosis Exhibition has been sent over the States in North America, local medical men in t various centres using the exhibition as a means of educati the public as to the prevention and cure of t disease. It is calculated that close on three-quart of a million of people have visited these exhibitions the United States of America. In a country like Irela where up to the present no decline whatever has taken pl in the occurrence of the death-rate from tuberculo resembling the decline in other countries such a step the instruction of the people as this exhibition will afford specially called for, but we believe similar aids would

TROPICAL DISEASES.

FRIDAY, AUGUST 2ND.

Discussion on the Hæmoflagellates.

Professor E. A. MINCHIN (London) introduced the subject of the Hæmoflagellates by remarking that the duty of zoologists was to study animals and animal life with a view to establish their place in nature and their affinities and relationship with other organisms. Medical men were, however, interested directly only in those departments of zoology which appertained to disease, so that a clue to methods of treatment or prevention of disease might be evolved. The naturalist and physician, however, found a common interest in studying the life cycle and development of parasites. Hæmoflagellates were comprised under that class of protozoa which had as organs of locomotion one or two flagella and were parasites in the blood of vertebrated animals. The two most prominent genera of hæmoflagellates were the trypanosoma and the trypanoplasma, the former characterised by possessing an undulatory membrane along the edge of which runs a flagellum projecting at one end, whilst the trypanoplasma has an additional free flagellum. The trypanosomes were parasites of vertebrates, the trypanoplasmata of fish; the former caused serious diseases in men and animals, the latter were looked upon as harmless. In the digestive tracts of insects were found two genera at least, herpetomonas and crithidia; they possessed flagella, but the undulating membrane was either absent or rudimentary. Of insects it was especially amongst the blood-suckers that these genera were met with, a circumstance which was highly suspicious, pointing to their being possibly only stages in the life-history of trypanosomes. It must be noted, however, that the Herpetomonas muscæ domesticæ—i.e., the parasite as met with in the domestic fly—was an independent species. Its presence in the fly had given rise to the theory that the house fly was at one time a blood-sucker. The question of including the spirochætæ amongst the hæmoflagellates and not amongst bacteria is still being debated, but the weight of evidence was now towards the belief that they were really protozoa. It must be noted, however, that a trypanoplasma might become a trypanosoma by the loss of the flagellum which was not connected with the undulating membrane, and a trypanosoma might be derived from a herpetomonas by shifting backwards the origin of the flagellum. The occurrence of herpetomonas forms in the developmental cycle of many species of trypanosomes might be interpreted as an indication of descent from a herpetomonas-like ancestor. Professor Minchin traced the life cycles of hæmoflagellates. Dealing with the herpetomonas of the house fly, he stated that the parasite lived in the intestine of the fly and became encysted in the hind gut, whence the cysts escaped and contaminating the food of other flies were swallowed by them, germinated, and were finally set free as parasites which at once commenced to feed and multiply. He called this the casual or contaminative method of infection as distinct from the direct and indirect transmission methods of infection as accomplished by blood-sucking flies. In direct transmission the parasite was taken up and handed back by the blood-sucking fly without having undergone any change or development; examples of this method were seen in nagana disease of horses and cattle and sleeping sickness in man. Indirect transmission signified that the parasite in the body of the blood-sucking insect underwent a series of changes before being given back again to a new vertebrate host; the malarial parasite in its passage from man to mosquito and back again from mosquito to man was the best known example.

Professor HANS ZIEMANN (Cameroons) stated that the fresh trypanosoma infections amongst animals in Lower Guinea were met with only during the rainy season. It was highly probable that the greatest number of fresh trypanosomal infections must be produced by the young brood of the blood-sucking flies which came out in the rainy season. Professor Ziemann said that as the enlarged spleen served as a basis for formulating the malarial index in man, so palpating the glands of animals, such as sheep, goats, and cattle, when possible would serve as a trypanosomal index in countries where trypanosomiasis prevailed; he found also that where sleeping sickness existed there would animals be found infested with trypanosomes, at any rate in the countries with which he was acquainted.

Dr. ANDREW BALFOUR (Khartoum) pointed out sources of error in insect examination as evidenced by the discovery of crithidia when looking for an extra-corporeal stage of the hæmogregarines of jerboas in fleas; he also mentioned Christophers's discovery of what was probably a coccidial cyst when searching for a similar stage of the hæmogregarine of Indian jerbils in lice; he stated that similar cysts had also been found in fleas in the Soudan. Dr. Balfour found a typical herpetomonas in Tabanus socius, the commonest serut of the Nile, and one which might possibly be the carrier of the trypanosome of the camel, at least in certain parts of the Kordofan Provinces. The stomoxys might not, according to recent evidence, prove to be the carrier of trypanosomiasis in the Soudan.

Sir PATRICK MANSON (London) considered that parasites evolved *pari passu* with their hosts and when these hosts diverged into species, genera, and families the parasites adapted themselves to the altered conditions; the genesis of parasites requiring two hosts dated, therefore, possibly from ancestors which in the history of evolution antedated the differentiation of the arthropods from the vertebrata.

Classification of the Hæmoprotozoa.

Sir PATRICK MANSON brought forward a Classification of the Hæmoprotozoa drawn up by Dr. Sambon. Dr. Sambon divided the hæmoprotozoa into four families: I. Hæmogregarinidæ, with one genus hæmogregarina. II. Plasmodidæ, with two genera, (*a*) plasmodium and (*b*) laverania. III. Spiroschaudinniidæ with three genera, (*a*) leucocytozoon, (*b*) spiroschaudinnia, and (*c*) treponema. IV. Hæmoproteidæ: (1) sub-family Hæmoproteinæ, with one genus hæmoproteus; (2) sub-family Trypanosminæ, with four genera, (*a*) babesia, (*b*) leishmania, (*c*) trypanosoma, and (*d*) trypanoplasma. Dr. Sambon based his classification upon the changes in the oökinete. In the hæmogregarinidæ and plasmodidæ the oökinete encysts, but in the spiroschaudinniidæ and hæmoproteidæ the oökinete remains free.

Dr. LOUIS W. SAMBON maintained that in sleeping sickness Glossina palpalis acted as a true alterative host and not merely in a mechanical way as suggested by Colonel D. Bruce, R.A.M.C., and Professor Minchin. Reproduction of the disease by inoculating the blood from the fly's gut, notwithstanding the presence of many active trypanosomes, had failed, proving that forms in the gut of the fly were gametes that must undergo a special development and were unable to reproduce by schizogony. In the clear fluid in the bulb of the proboscis Koch had found numerous trypanosomes; these were evidently the forms ready to be inoculated into a fresh vertebrate host, leaving by the proboscis and not by the intestine. Brumpt and Leger had shown also that trypanosomes of fish went through a sexual cycle in leeches and each species had its specific leech host. Until the part played by Glossina palpalis was thoroughly worked out it was impossible to formulate an efficient prophylactic system.

Dr. W. C. PROUT (Liverpool) contributed a paper on

Blackwater Fever.

In blackwater fever a history of repeated attacks of malaria fever was to be obtained. Amongst the signs and symptoms it would be found that during the stage of hæmoglobinuria the quantity of urine passed was increased, but diminished as the urine cleared. Dr. Prout instanced cases of acute nephritis with hæmaturia mistaken for blackwater fever. Bilious remittent fever and jaundice had also been diagnosed as blackwater fever. The prognosis was not so universally unfavourable as was generally supposed. In regard to treatment the first indication was to get rid of the morbid products by means of the various excretory organs of the body. Calomel was the best purgative. Intravenous injection of normal saline solution was the most efficacious of remedies in very bad cases. The second important step was to counteract the malarial element in the attack; quinine should be given when malarial parasites were found, at least in one dose, watching effects. Supporting the strength and alleviating any distressing symptoms by every available means were urgently called for in all cases of blackwater fever.

Dr. F. W. MOTT and Dr. HELEN G. STEWART (London) contributed a paper entitled

Some Further Observations on the Cell Changes in Dourine and Sleeping Sickness.

After sketching the work already done in elucidation of the nervous system changes in sleeping sickness the writers stated that from further investigations of the tissues already examined and reported upon they had found in a dourine it is not constant and in adults it must be regarded as pathological. A further interesting proof of the occurrence of hæmolysis in typhoid fever was afforded by the investigation of the lymphatic apparatus at the necropsy of a young man, aged 25 years, who died from a severe attack of typhoid fever, bacilli having been found in the blood during life. No intestinal hæmorrhage occurred and there were no indications of a hæmorrhagic diathesis, but in addition to an intense deposition of hæmosiderin in the liver and spleen a similar deposit was found in nearly all the lymphatic glands except the mesenteric, as well as in the tonsils. The hæmosiderosis was very marked in the retroperitoneal, parapancreatic, axillary, and cervical glands. The Berlin-blue method gave blue staining of the lymph channels throughout their course, the pigment being deposited in the large cells which crowded these channels and not in the actual parenchyma of the gland. That this formation of hæmosiderin was of recent date, and indeed in actual course of progress, was proved, since in addition to the cells containing that substance and others with iron-free pigment granules, red corpuscles and cells with ingested red corpuscles were abundantly present in the perifollicular lymph paths, especially in the cervical and axillary glands. These observations were confirmed in three cases subsequently examined. From these appearances Professor Schmidt infers that in typhoid fever the red corpuscles which have suffered damage in the general circulation are taken to the lymphatic glands either by the blood stream or lymphatic channels in order to undergo some further change. These observations are of considerable interest, not only from the light they throw upon the action of the toxins of the typhoid bacillus but also from their importance in connexion with the processes of hæmolysis in general.

AFFECTIONS OF THE OPTIC NERVE.

THE oration before the American Academy of Ophthalmology and Oto-Laryngology, delivered in September, 1906, by Mr. R. Marcus Gunn, senior surgeon to the Royal London Ophthalmic Hospital, has recently been published.[1] Mr. Gunn's experience, with the special opportunities which he has enjoyed as ophthalmic surgeon to the National Hospital for the Paralysed and Epileptic, may be gauged by the fact that he has seen over 900 cases of choked disc. A paper which reviews all too briefly such ripe experience will be read with unusual interest and profit. The various causes of disease of the optic nerve are first enumerated, stress being laid upon peculiarities of structure and development which help to explain the lesions. It is suggested that the afferent pupillary fibres are collaterals of the visual fibres, a view which is supported by the loss of reflex constriction of the pupil in the Argyll-Robertson phenomenon, for it has been shown that in tabes the collaterals of the fibres of the posterior columns of the cord suffer first. Mr. Gunn agrees with many modern observers in thinking that primary destruction of the retinal ganglion cells is commoner than was formerly thought. Examples are to be found in amaurotic family idiocy, probably in tobacco amblyopia, and possibly in cerebral diplegia, abiotrophy, and so on. Primary affection of the myelin sheaths is instanced in disseminated sclerosis, the early visual signs of which are best explained by defective insulation and rapid exhaustion. The theories of the choked disc of intracranial disease are reviewed. As Mr. Gunn picturesquely remarks: "The field is notoriously slippery; there are occasional pitfalls, too, and false lights play upon what appears to be a path to the gateway of knowledge." He adheres to the original theory of von Graefe, which attributes the condition to disturbance of the circulation produced by increased intracranial pressure. He rightly emphasises the fact that the condition is primarily an œdema, true inflammatory signs being present only in later stages. The relative infrequency of choked disc in myopic eyes affords evidence of the importance of local anatomical factors, and the most likely one is the mode of ending of the intervaginal space. Obstruction to the return of blood from the papilla by pressure on the pial veins is a contributory cause of papillitis in these cases. We have sufficiently indicated the scope of the oration, and we hope that Mr. Gunn may elaborate his opinions and publish them in some more permanent form.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN London during the last fortnight a few cases of epidemic cerebro-spinal fever were notified from widely-separated districts, including Battersea, Shoreditch, and Woolwich. In Scotland during the week ended August 31st there were ten deaths from this cause registered in Glasgow, two in Dundee, one in Aberdeen, and one in Paisley. In Glasgow the weekly report issued on August 30th showed that there were at that time 38 cases under treatment. In Belfast during the week ended August 31st there were seven deaths registered as being due to this cause.

LIQUID AIR IN DERMATOLOGY.

IN the *Journal of the American Medical Association* of August 3rd Dr. Henry H. Whitehouse gives his personal experiences in the use of liquid air in dermatology. A mild and short exposure of the normal skin to a spray of liquid air produces blanching, followed by a moderate congestion; a longer exposure freezes and anæsthetises the part. In applications by means of a swab of cotton wool the resulting inflammatory swelling varies in degree according to the amount of liquid used, the pressure applied, and the location and character of the tissues. The pain produced is very slight and rarely lasts long. In pathological conditions liquid air relieves pain after a few applications and lessens discharge and odour; it diminishes tendency to hæmorrhage and encourages healthy granulation. It produces very little reactionary effect on scar tissue, hence it is of distinct diagnostic value in epithelioma. Dr. Whitehouse points out that extravagant claims were at first made for liquid air in the treatment of many disorders which may be more conveniently treated by simpler methods, including abscess, bubo, boils, carbuncles, ulcers, and warts. It is unnecessary, also, to resort to liquid air for the production of local anæsthesia. There are, however, many disorders in which better results may be obtained with liquid air than with other remedies, particularly in pigmentary, hairy, and vascular nævi, angiomata, lymphangioma circumscriptum, lupus erythematosus, lupus vulgaris, and epitheliomata. Dr. Whitehouse suggests that the secret of success with liquid air lies in the technique. The cotton swab is applicable to all conditions and with a little experience can be used with great precision. Fine sticks of sufficient length to reach the bottom of a Dewar bulb, and so shaped that the liquid may be applied in any quantity, are bound at the end with absorbent cotton to form a flat, round-pointed, or paddle-shaped pad. The excess of liquid should be shaken off and scabs should be completely removed from all lesions to be treated, a thin layer of gauze intervening between the applicator and all mucous or denuded surfaces, otherwise the scab will freeze fast. The factors governing the effect produced are the degree of saturation of the swab, the accuracy of contact, the amount of pressure exerted, and the duration of the exposure. The success of the treatment depends upon a thorough appreciation of these factors coupled with correct judgment respecting the interval allowed between exposures.

---

[1] Ophthalmology, January, 1907.

sine emetina seemed well-nigh as efficacious as the ordinary drug. With ipecacuanha he expected by the third day to find the tenderness of the tongue, the ulcers on the tongue and mouth, the febrile state when present, and the bulk and frothiness of the stools to disappear. As an intestinal injection he used warm sea-water one pint every second day. The lactic acid treatment recommended on theoretical grounds by Metchnikoff was detrimental, as it increased the acid fermentation already present. Mr. Cantlie advocated entire exclusion of milk from the diet, and found meat and fresh vegetables, such as vegetable marrow, stewed celery, and seakale, with fresh or cooked fruit the suitable diet in sprue.

Dr. P. J. CAMMIDGE (London) stated that in 14 cases diagnosed as sprue he had found pancreatitis in six. The urine gave well-marked "pancreatic" reaction. Urobilin and indican were present in abnormal quantities. The fæces were acid as a rule. In cases of sprue associated with pancreatitis there was, as a rule, a somewhat higher proportion of unsaponified fat than in uncomplicated cases. It would seem that in almost 50 per cent. of cases of sprue the disease spread to the duct of Wirsung, causing first a catarrhal and subsequently an interstitial pancreatitis.

Dr. W. H. DE SILVA (Ceylon) gave

An Account of the Climate of Ceylon,

and claimed that as a winter resort for invalids, especially those suffering from bronchial troubles and those requiring a thorough rest, Ceylon offered many advantages. The best months to spend in Ceylon were from December to March. There could be no doubt that in the upland districts of Ceylon there were most desirable places of residence, where climate, scenery, and environment had many attractions.

Dr. H. RADCLIFFE CROCKER (London) contributed

Some Observations on the Cases of Tropical Skin Diseases

which had come under his observation. He stated that tropical ringworm was not always of the same type, and that in Britain the signs and symptoms apparently disappeared in winter and recrudesced in summer. Discussing elephantiasis, Dr. Crocker said that in the tropical variety the trunk lymphatics were blocked and the skin was smooth and unchanged, whereas in the streptococcic elephantiasis the surface was affected with granulation growths and epidermic thickenings.

Mr. CANTLIE gave

An Account of 100 Consecutive Cases of Liver Abscess

which he had operated upon. Of the number, 82 recovered and 18 died. 90 of the cases he had operated upon transthoracically by the trocar and cannula and syphonage method of treatment. 47 of the cases were of the class suprahepatic, three subhepatic, and the remainder intrahepatic.

Mr. CANTLIE also read a paper on

The Anatomy of the Sigmoid Flexure,

showing that at the upper and lower end of the sigmoid flexure there existed normally a pylorus or gate of entrance and of exit respectively. Here the circular muscular fibres were thickened and the longitudinal bands of muscular fibres approached each other constituting an anatomical and physiological gate, pylorus, or valve. In chronic lesions of the lower bowel these were the seats of congestion, ulceration, granulation growths, and stricture of a fibrous type. The conditions which these lesions caused were: mucous casts, mucous colitis, chronic diarrhœa, and a condition resembling, or identical with, chronic dysentery. Mr. Cantlie treated cases of the kind by dilatation with rectal bougies introduced through the sigmoidoscope, applying the principles of treatment of urethral stricture to sigmoid stricture. The treatment had proved eminently successful.

NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, JULY 31ST.

Inspector-General J. PORTER, R.N., the President of the Section, delivered

The Introductory Address.

He said: I feel I cannot let this occasion pass without warmly congratulating the Army Medical Service on the vast, the revolutionary, strides it has made in recent years towards complete efficiency. This appears to have been rendered possible by a happy combination of many fortunate circumstances. 50 years ago a great War Minister, Sidney, Lord Herbert of Lea, planned and strove with all his might for most of the reforms which have only now been introduced. He fought a brave fight, but the forces arrayed against him prevailed. His biographer tells us how the Treasury, the bureaucracy of his own department, soldiers, and medical men, hide-bound in tradition and seniority, obstructed in their several ways and hastened this noble statesman's end. The service rolled on in the old grooves undisturbed till 1882 when our little wars in Egypt began. History repeated itself; a medical breakdown led to an outcry in the country. The usual official inquiry was held and with the old result. No one was to blame except a few medical small fry who failed to show initiative or to take responsibility under a system which had given them no authority over, or training in, war duties during peace. Once more things went to sleep, and so it came about that South Africa told practically the same sad medical tale. But at last the hour had come and with it the men who were to translate Sidney Herbert's work, and much besides, into reality. Conspicuously to two War Ministers (Mr. Brodrick and Mr. Haldane), to Earl Roberts, and to Sir Frederick Treves the country and the army owe the medical position of to-day. Promotion by merit has been established through all ranks of the Army Medical Service. Its officers have been given a career. The paralysing blight of seniority has been swept away and healthy development has been assured. There is no room for the idle, the ignorant, the incompetent—the man now exists for the office and not the office for the man. Already in all around the strenuous life is in evidence. To take two examples: The monthly *Journal of the Royal Army Medical Corps* is a publication of which any body of professional men might be justly proud. The corps specialists, too, are forging ahead. The detection by Colonel Bruce of the micrococcus Melitensis has, to quote a recent newspaper article, led up to the crowning discovery of Major Horrocks "that goats and their milk are the chief means by which Mediterranean fever is spread." Thanks to the magic effect of this revelation Malta and the Mediterranean, for long our deadliest foreign stations, are becoming exceedingly healthy. A few months ago the Secretary of State for War took a step of the first importance when he ordered that the principles of sanitation and hygiene should become an integral part of the training and essential qualifications of all combatant officers. In the medical service of the Royal Navy many improvements have been made during the past decade. New hospitals have been built and old ones extensively reconstructed. Modern fittings and equipment have been supplied afloat and ashore. Dental surgeons have been attached to the great hospitals at our principal home ports, and, what is of the highest value, medical officers in steadily increasing numbers are being given courses of study at civil hospitals. (The President referred to the recent war in the Far East and after describing the hopeless inefficiency of the Russian medical service under the old system and its deadly effect on the health and morale of the forces, proceeded:—) Let us turn from this to the other side and we see what years of careful study, judicious outlay, and patient practice accomplished for Japan. The lucid articles of Surgeon-General Suzuki, Admiral Togo's principal medical officer, are a perfect gold mine of information. Nothing was left to chance. Did time permit they contain much that one would love to dwell upon. Tsushima was won by our allies at the small cost of 113 killed and 424 wounded, many due to burns. At the recent Red Cross Congress in London Dr. Nagas Ariga stated that the Japanese in their late war had to deal with 220,812 wounded and 334,073 sick soldiers, exclusive of 77,809 Russian prisoners—that is, roughly, for every three sick there were two wounded, a very different ratio compared with anything we have ever known. To quote an example within my own experience, in 1884-85 I was for a year in the field on active service with a battalion of marine infantry. It was maintained at a strength of about 500 officers and men, and during the year approximately 1500 joined. The enemy accounted for less than 100 in killed and wounded; the remaining 900 were accounted for by deaths and invalidings. We owe it to our sailors and our soldiers, it is our duty to our country, to strive with all our might after the standards of medical efficiency with which our gallant allies have surprised civilisation. My brother officers, I know, realise that we cannot afford to, we simply must not, have medical blundering in our next war. South Africa showed us that to some extent the soldier can be replaced by the Empire in arms, but with the sea service it is otherwise. Press-gang, conscription, merchant service, which filled the

REPORTS OF THE ROYAL COMMISSION ON HUMAN AND ANIMAL TUBERCULOSIS.[1]

I.

Dr. A. S. Griffith's report "On the Pathogenic Effects of Bovine Viruses" forms the first of five volumes which record in detail the work done by different members of the scientific staff of the Royal Commission on Tuberculosis at the farms and laboratories at Stanstead. Dr. Griffith had charge of the experimental work on bovine viruses which was carried out at the Walpole farm and kept strictly apart from that done on viruses of human origin at the neighbouring Royalcote farm. The main objects of the experiments described in the volume were (1) to provide a basis of comparison for the experiments with tubercle bacilli of human origin; (2) to ascertain whether the different viruses obtained by the Commission from naturally occurring bovine tuberculosis varied in virulence; and (3) to test the susceptibility of different species of animals to the bovine tubercle bacillus. The material employed was obtained from 30 different bovine animals. The cases were representative of the ordinary forms of natural tuberculosis met with in the ox and included cases of severe general tuberculosis, slight general tuberculosis, and tuberculosis limited to certain glands. Dr. Griffith's account of the experimental work is classified according as these bovine viruses were tested by inoculation or by feeding. The inoculation experiments are set out in the first portion of the volume, each virus having a chapter to itself, with its appropriate genealogical table showing the various animals which received doses of bacilli belonging to the virus in the course of the protracted series of experiments which were made in each case. Inoculations were made partly with emulsions of fresh tuberculous material and partly with cultures obtained either direct from the original material or from one of the animals (usually a guinea-pig) which had been inoculated with the virus. The culture medium was pure serum, usually ox serum.

Estimation of the dose of tubercle bacilli administered.—Approximate estimation of the bacilli in the infective material administered was, of course, essential to the work. The method of estimating the number of bacilli present in emulsions is described in detail by Dr. A. Eastwood in a preliminary chapter. The samples of emulsion were received in the laboratory in sealed test-tubes. A preliminary film is examined to see whether dilution with normal saline is desirable, a proceeding which in the case of tissue emulsions is rarely necessary. Five cubic millimetres are measured on to cover-slips by a Nabarro's pipette. Each film is stained for at least 20 minutes and after staining is discoloured by 25 per cent. HCl. Counting by the method described takes from 40 minutes to two hours for each film. Dr. Eastwood has found it nearly always practicable to count the bacilli when these occur in clumps: groups containing from 50 to 70 bacilli have been common, but groups containing more than 100 have been very rare. In the case of cultures the emulsified bacilli are centrifugalised and their bulk is measured. A cubic millimetre of centrifugalised bacilli is reckoned as equivalent to a milligramme of tubercle bacilli. In the case of serum-grown bacilli a cubic millimetre, according to Dr. Eastwood, may be taken roughly as containing from 4000 to 5000 millions. The great majority of culture inoculations have been far richer in bacilli than inoculations with even the largest dose of tissue emulsions.

Results obtained by inoculation of bovine viruses.—The principal value of the large series of inoculation results obtained with each bovine virus consists in providing standards and contrasts with the results of corresponding series obtained from human viruses, which Dr. L. Cobbett describes in the second of the volumes now issued by the Commission. These contrasts have been fully brought out in the Commission's second report. Looking at the results of inoculation of bovine viruses by themselves it is seen that *cultures* (whether from the original material or from lesions in animals inoculated with the original material) produced in calves when given in 50 milligramme doses general tuberculosis of all the organs and glands of the body. This general tuberculosis is usually of a very acute type, and in the greater proportion of instances kills the animals within 50 days. Even five milligrammes of culture produced fatal general tuberculosis in a calf, although in one series of calves injected each with ten milligrammes, one case occurred in which inoculation produced only a "minimal" form of disease. The result of injections of *emulsions* of tuberculous lesions, in which the dose of tubercle bacilli was much smaller than when cultures were employed, was not dissimilar. Generalised disease was frequently produced in bovines so inoculated. Instances are noted in which, when a "minimal" lesion was produced in a calf by the injection of an emulsion, a virulent culture was afterwards obtained from this lesion. Injected into rabbits, cultures of the bovine bacillus produced general tuberculosis in doses of 0·1 milligramme; emulsions always produced general tuberculosis in whatever dose given. The contrast of these results with the effect of the human virus on the rabbit is a point on which the Commission laid special stress in their second report. Other animals—pigs, goats, and monkeys, readily acquired general tuberculosis by inoculation with the bovine virus. Rats, on the other hand, were highly refractory.

Dr. Griffith draws attention to instances where a virus taken direct from calcareous and retrogressive bovine lesions produced very much less effect than the same virus after it has been passed through the body of the guinea-pig, although in each case the number of bacilli inoculated has been the same.

Immunity experiment.—One of the calves inoculated with a tissue emulsion was made the subject of an immunity experiment. This animal made an apparently complete recovery after inoculation, at the age of 15 weeks, with an emulsion from the tuberculous prescapular gland of another calf, the dose being about 100,000 tubercle bacilli. The calf was re-inoculated 159 days later with a large dose, 25 milligrammes of culture from bovine material. After disturbances comparable to those produced by the inoculation of tuberculin into a tuberculous animal the calf again recovered. Subsequent inoculations of 50, 100, and 229 milligrammes of culture (enormous doses) at intervals of 215, 481, and 566 days after the primary inoculation respectively produced nothing more than a local swelling and transient illness.

Excretion of bacilli in milk.—A cow in which generalised tuberculosis was set up by inoculation of a large dose of culture was ascertained to excrete milk which caused tuberculosis in guinea-pigs, although the udder was normal to the naked eye. In this instance, however, Dr. Griffith concludes from the results that only a small number of tubercle bacilli were excreted with the milk, notwithstanding that the quantity of bacilli circulating in the blood stream must have been exceptionally large.

Results obtained by feeding with bovine viruses.—The feeding experiments made with bovine viruses described in the second part of the volume contain many points of interest. Dr. Griffith draws attention to various conditions which may influence the result of introducing tubercle bacilli in this way, particularly when the administration is effected by giving a single dose of infecting material. Among these are catarrh of the mucous membrane which, by hastening the expulsion of the intestinal contents, may result in the animal escaping infection; and structural differences in the alimentary canal of different species of animals. Bacilli can be very readily absorbed from the alimentary tract in pigs, for example, but much less readily in guinea-pigs. As a whole, the experiments bring out certain facts as to susceptibility of different species of animals which are confirmed by subcutaneous injection. The animals used in the investigation could be classified into three groups: (1) animals in which the bovine virus, however small the dose, almost invariably gives rise to general progressive tuberculosis—chimpanzee, baboon, rhesus monkey, lemur, rabbit, and guinea-pig; (2) animals in which general progressive tuberculosis can be set up, but where its occurrence depends upon the dose of the infecting agent and the age of the animal—pig, goat, calf, cat, and dog—of these the young pig is the most susceptible and the adult dog the most resistant; (3) animals apparently insusceptible to tuberculosis by feeding—rats and fowls.

The course of infection in feeding experiments.—This is a matter of great importance in its bearing on human tuberculosis, and Dr. Griffith points out that tubercle bacilli often have been found to pass through the pharyngeal or intestinal enterio fever in the 17th Lancers at Meyrout, the dry earth latrine system was discontinued in the regimental lines and a 2 per cent. solution of crude carbolic acid was substituted, a supply being put into each pan to receive the fæces. As a result of this the flies at once disappeared from the latrines, although neighbouring native latrines where dry earth was still used contained as many as ever. Bearing the above facts in mind the extreme importance of covering fæcal matter could be appreciated, especially if some system of latrine accommodation was used which comprised the reception of such matter in a liquid medium. The realisation of such a system would appear to be found in the latrine of the United States army which consisted of a portable latrine trough of galvanised iron. The trough was partly filled with milk of lime, solution of carbolic acid, or other liquid of like nature, and emptied when required into an air-tight cart by means of a suction pump. The official report of the United States Government stated that medical officers were aware of the fact that that method of disposing of fæcal matter would be attended by increased cost, but they were confident that it would greatly lessen the number of cases of typhoid fever. It was evident, according to Lieutenant-Colonel Caldwell, that the advantages of that system would not find their limitation in the disposal of solid excreta, but would also go far to eliminate the danger of the spread of enterio fever by infected urine. In regard to the spread of the disease by contact with the sick they found themselves confronted by the possibility that men who were not thought ill enough to be put on the sick list might be acting at the time as wholesale disseminators of epidemic disease.

Surgeon-Colonel P. BROOME GILES, V.D., communicated a paper on

The Position of the Volunteer Stretcher-Bearer.

He defended the retention of the present unit system of regimental stretcher-bearers for the following reasons: 1. In war the actual fighting zone, where the first line of medical assistance was immediately wanted, was not protected by the rules of the Geneva Convention. The exhibition of the honoured Red Cross flag was not respected under fire. If it were so the temptation of temporarily exhibiting it upon strategical positions would be irresistible. 2. All the other lines of medical assistance were protected under the Geneva Convention. They could not have the Royal Army Medical Corps protected one moment and liable to be fired upon the next. 3. There was the sentimental but not the less true idea that men fought better when they knew that should they fall they would be as speedily as possible succoured by their own comrades; that comrades would at all risk help each other. 4. Recent wars, especially those in South Africa and Manchuria, had amply proved: (*a*) that the frontal area of their attack had enormously extended and at the commencement of an action the ranks were not so crowded as formerly but that the persistent fire was far more effective, each ridge of ground being bullet-riven for hours; (*b*) that often in battle hours, even days and nights might elapse before the fight passed by or was ended. To use trained men of the Royal Army Medical Corps as regimental stretcher-bearers would be a waste of material. They were too valuable to be exposed in the fighting line. No doubt in the future men of the Royal Army Medical Corps would be attached to units for sanitary duties. In his opinion the regimental stretcher-bearer must continue to exist, and if they used stretcher bearers such as were contemplated to complete the war establishment of the field ambulances they could only be employed efficiently after the battle was over.

FRIDAY, AUGUST 2ND.

Major N. FAICHNIE, R.A.M.C., read a paper on

Water supply in Camps, on the Line of March, and in Battle.

He was strongly of opinion that to prevent the occurrence of typhoid fever it was necessary to have a pure water-supply for at least two objects—namely, for drinking and for washing up. Any form of analysis required time; it was impossible even for an expert to say merely by looking at it whether a water was good or bad. There were certain facts about water which every officer and every soldier must understand, the most important being that all water must be considered bad and none that had not been purified should be used. The usual rules for protecting water must be strictly enforced, but in addition all water must be purified, not for drinking only, but for washing up as well. Every time a water-bottle or water-cart was filled with unsafe it became impure and remained unfit for use till sterilised. In Major Faichnie's opinion the regulation water-bottle co not be properly cleansed inside, and because of this in climates it became offensive; the outer covering of fe of the bottle should be attached to the sling, that the bottle could be drawn out and put directly on the fire, thus providing an alternative method o purifying both water and bottle; further, the mouthpiec became coated with dust, which was removed by an un washed hand or a dirty handkerchief. These defects, speaker contended, could be removed by the employment the water-bottle which he had devised. It was made aluminium and the lid containing the neck lifted completely, so that the inside could be thoroughly cleans by the hand when necessary. The bottle could be put o the fire. It had been refused by the War Office as unsuitable, but Major Faichnie still believed that the regulation water-bottle could be improved by the adoption all or any of the advantages which his water-bottle

Lieutenant-Colonel E. M. WILSON, R.A.M.C., read a on

The Necessity for Trained Male Personnel in the Medical Services on Mobilisation for War.

He said that of all things the most important to a genera was to get his fighting line cleared of sick and wounded and it was essential that the personnel should be trained, as trained team would carry a patient twice the distance with less fatigue and less suffering to the injured man than otherwise be the case. The nursing staff and all medi officers would gratefully bear witness to the splendid performed by sisters and nurses in military hospitals peace and in war, at home and abroad, but there other duties which must be performed in all hospital if the administration was to be satisfactory. The lines on which it was hoped that the medical might be organised in future expeditions were: (1) to place a sufficient number of non-commissioned office and men with the units in the field, trained in the fi principles of sanitation, and with some knowledge of the means and appliances for the purification of water, and thus to prevent disease; and (2) to increase the number of bearers with field ambulances, and thus more rapidly to remove non-effectives from the front. In this way it was believed that the percentage of sick be decreased and the number of hospitals required pro portionately diminished. The provision of these trained medical subordinates was, of course, a question for the War Office, but he thought that medical men in all parts of the United Kingdom might do something to assist. A scheme was under consideration for the St. John Ambulance Brigade to take over the charge of military hospitals at home on mobilisation when the Royal Army Medical Corps officers and men were withdrawn for active service. That could not be done successfully unless medical men resident in the locality would take an interest in the scheme and assist in the instruction.

Major R. J. BLACKHAM, R.A.M.C., read a paper on

The Teaching of Hygiene in the Army.

He said that the lines along which the teaching of hygiene might be further extended in the public military schools might be these: The training of quartermasters in hygiene and the institution of examinations in sanitation for officers of this class prior to promotion; the teaching of hygiene to soldiers in army schools as an essential subject for the various military certificates of education, and the adoption of hygiene as a compulsory subject for pupil schoolmasters at the Duke of York's School and for all steps in the schoolmaster's promotion; the training of army schoolmistresses in infant hygiene at military families' hospitals and the instruction of elder girls in army schools in the care of children; the opening up of certain staff appointments involving executive military duties to military medical officers; and the extension of the system of hygienic training adopted for regular troops to the voluntary or territorial forces and the appointment of regimental medical officers as sanitary rather than surgical experts.

Surgeon P. T. SUTCLIFFE, R.N., read a paper on the Treatment of Burns and Scalds Afloat, in which he advocated the use of a 5 per cent. solution of picric acid in place of carron oil.

may commit. It is pretty safe to assert that this attitude affords no security whatever to the public. The fact remains that material that may be no better than manure is being used for making bedding without any attempt being made to render it clean and wholesome by the scientific process of sterilisation by steam. There must be a number of filthy beds in the land and it is not improbable that this fact accounts for some mysterious outbreaks of disease.

We repeat that these circumstances demand immediate legislation and the application of an obvious and simple remedy—a remedy which some manufacturers already apply on their own initiative, though seriously handicapped by the silly demand for the cheaper, because untreated, material. It is also desirable that the public should not be beguiled into buying cheap bedding which is falsely described as "sanitary" or "purified" when the material has undergone absolutely no such cleansing process as is implied by the above terms. This species of fraudulent trading should, of course, be dealt with under the Merchandise Marks Act, which exists to suppress false trade description.

MEDICINE AND THE LAW.

The Case of a Trooper in the Yeomanry suffering from Chronic Urticaria.

On August 21st Mr. Horace Smith, sitting at the Westminster police court, dismissed a charge of an unusual character against a trooper serving in the Middlesex Imperial Yeomanry, but residing at Birmingham, based upon his absence from the annual training of his corps. The defendant had served in South Africa in Paget's Horse and since then had regularly attended the camps of his own corps, the Middlesex Yeomanry. This year he applied in April for leave to be absent from camp, which takes place in July, on the ground of business, but as he could not be excused without making a payment he prepared to attend. About the same time, finding that he was unwell he consulted his medical attendant and was treated for nettlerash. As it still gave him trouble when the time for the annual training approached he communicated with the Yeomanry authorities, and in consequence of a correspondence in which it was insisted that he ought to proceed to London and be examined by Mr. C. Stonham, the surgeon of his corps, he forwarded three certificates to the effect that he was suffering from urticaria and that he was not fit to go into camp. Apparently the fact that no mention of the chronic nature of the complaint was made, coupled no doubt with some want of explicitness in the information supplied as to his condition, caused the officers of the Middlesex Yeomanry, anxious to maintain their numbers in camp and to prevent what is known to military men as "skrimshanking," to regard the certificates sent with scant respect. The trooper was arrested and brought to London as a deserter, and after adjournments his medical witnesses were compelled to attend the court in support of their certificates. The evidence thus given was that Mr. Walter Flewitt, the usual medical attendant of the defendant, Lieutenant-Colonel S. E. Duncan, R.A.M.C., medical officer in charge of troops at Birmingham, and Mr. Edwin Gilbert Smith, senior surgeon to the Birmingham Hospital for Diseases of the Skin, had all personally examined the patient at the time when their certificates were given and had formed the opinion that he was not fit to go into camp where he would have to undergo a certain amount of exposure and hard work and where special treatment would be impossible. In the circumstances the charge was, as a matter of course, dismissed, and it seems a matter of regret that it should have been brought. Still the point is not quite as simple as it seems. Urticaria, as a rule, is little more than a temporary inconvenience; it gives rise to annoyance and discomfort for a few days or even a week or two, but with the elimination of the toxins which have produced it the whole trouble ceases. There is, however, a chronic form in which the irritation is very persistent and this may materially interfere with the work of the patient. Especially is this the case when the local vaso-motor centres are in that unstable condition to which the name of "dermographism" is given and this is what was indicated by one of the medical witnesses who said that the patient was suffering from "urticaria factitia." In this condition pressure on the skin may immediately produce a wheal. We can quite understand that this condition would materially interfere with active work in the Yeomanry. We do not know the exact form of the certificates given, but in all cases where a medical certificate is intended to state that a person is unable to perform his duties the certificate should be as explicit as possible, so that the condition of the patient should be clear to any other medical man.

Medical Men and County Court Procedure.

Some attention has been aroused on the county court circuit presided over by Judge Mulligan, K.C., owing to the attitude adopted by his honour towards a form of procedure which was sanctioned by his predecessor, Judge Willis, and which, though not universal, obtains elsewhere as well. Judge Mulligan will not allow debt collectors to appear before him to prove the debts owing to their clients. This is a matter which affects medical men generally because they are often obliged either to sue for fees or to lose them, while they have little time to appear as witnesses or to conduct their own cases in court. More particularly it also affects them because Judge Mulligan, in disposing of certain cases at a recent sitting held by him at March, Cambridgeshire, made special reference to those in which medical fees were sought to be recovered, to the effect that "professional gentlemen ought to know better than to employ the clerk of a firm of accountants to represent them in a court of justice." These observations we regret; they were passed upon gentlemen who were not present to explain their position, and who probably had never regarded the question from the point of view suggested, but had merely adopted a practice which had been recognised and universally pursued before the recent appointment of Mr. Mulligan, K.C., to his present post. The practice referred to appears to be as follows. In order to establish a claim against a defendant in a county court when it is disputed a solicitor is, or may be, employed who in turn may brief a barrister, and witnesses are brought to the court who can prove the facts by going into the witness-box and giving evidence. There are many debts, however, which are not disputed by those who owe them but in order to recover which the judgment of the county-court judge is applied for. Some of these debts may be very small, a matter of one, or two, or three pounds, a great deal less than the fee of the advocate and the cost of the witnesses. When the sum recovered is so small little or nothing is allowed for "costs." Even if the plaintiff is his own advocate, and if his evidence is all that is required, he loses time and has to undergo a good deal which is not agreeable. It has consequently been found of advantage to employ a debt collector who charges a fee fixed in proportion to the amount recovered and who proceeds in this way. He takes an assignment of the debt from the creditor and gives notice thereof to the debtor, thus enabling himself to sue as if he were the original creditor. He also approaches the debtor with a view of obtaining payment and in doing so gets from him an admission that he owes the debt. Thus armed he initiates county-court proceedings and goes to the court to prove the debt by means of the admission or, as in the case referred to above, sends one of his staff to represent the firm. In dealing with a large number of cases at March in which this course had been adopted Judge Mulligan did what he has done at other places on his circuit with a view to stopping a practice of which he disapproves. He carefully scrutinised the details of each case, insisted upon the proof that the necessary notices had been given and that the documents were in order, and in the case of those purporting to be assignments of the debts in question he ruled that they were not properly stamped. By the end of the day he had struck out a large number of claims of this kind and in the course of some concluding observations he used the words which have been quoted above. His reference to medical men as professional men who should have acted otherwise was no doubt not merited because, as we have suggested, the practice which the learned county-court judge seeks to do away with had been long recognised before he was raised to the county-court bench and is, we believe, permitted to a greater or less extent in other courts. It also has the merit of simplifying and of rendering inexpensive the recovery of just debts. His point, however, is worthy of consideration. He invited, though in undesirable terms, the attention of medical men to the position of lawyers, who have to earn their livings by their profession, and

Trypanosoma.

The important economic bearings of pathological researches were well illustrated by Mr. H. G. Plimmer's exhibit of trypanosoma. This protozoon has for many years been found in the blood of the natives of Africa and for a *long time was thought to be quite harmless.* This view was due to the length of the latent period and the chronic progress of that lethal disease "sleeping sickness" which is now known to be produced by the trypanosoma which invades the cerebro-spinal fluid in large numbers. The organism, which is a fusiform one with flagellated ends, has been found by Bruce in the blood of 75 per cent. of the natives of Uganda, one of our youngest protectorates, and "sleeping sickness" is now spreading from Uganda to the natives of the Soudan and of Egypt. It is almost certainly communicated by the bite of some insect, some fly or mosquito—which is not yet certain. At first regarded as innocent, various forms of trypanosoma are now found to be extremely deadly both to man and animals. To their ravages have been traced the following diseases: the "tetse-fly disease," which decimated our horses in the South African war; dourine (mal de coït), a disease in horses producing mucous plaques on the penis and vagina closely resembling syphilis and communicated in the same way; and surra, a disease which in India destroys thousands of agricultural animals annually. In India immense tracts of land lie uncultivated year after year owing to the lethal epidemics of surra which have destroyed every horse, sheep, and camel in certain districts. Apart from their scientific value it would be difficult to overestimate the economic potentiality of such researches. Investigations into the realms of the protozoa have recently made wonderful progress. Apart from the undecided question of a protozoon being the parasite of cancer, there are at least two species of protozoa which are now known as most ubiquitous and lethal, trypanosoma and spirochæta pallida (of syphilis), both of which, as above noted, give rise to an almost identical granulomatous lesion.

Several observers sent in their names to demonstrate the spirochæta pallida at this museum but they failed to exhibit them. There was only one specimen, a very good specimen, shown by Dr. H. Bayon (London) from the liver of a syphilitic child impregnated with silver nitrate.

It will already be understood from the foregoing that this annual museum affords an excellent opportunity for us in Great Britain to see what is being done by our professional brethren in Greater Britain, and many instances might be given. Professor A. R. Ferguson (Cairo) and Professor W. St. Clair Symmers (Belfast) showed an interesting series of specimens illustrating the lesions produced by the bilharzia hæmatobia, a nematode worm associated with hæmaturia. The bilharzia is almost confined to Egypt, South Africa, and the West Indies, and its pathological first cousin, the Chistosomum japonicum, is found only in China, Japan, and India. They both produce similar symptoms and lesions and it could be readily understood from the specimens shown how the papillomatous lesions of the bladder, the rectum, and the great intestine might easily be mistaken for carcinoma or for dysentery not only during life but after death even by the most competent observers. Without searching carefully for the characteristic monopolar eggs of the bilharzia it would be impossible to distinguish bilharziasis from these conditions with certainty. Bilharziasis is probably more common than is generally believed and many cases are certainly mistaken for these conditions. Specimens from the liver in such cases show a special and distinctive kind of cirrhosis—viz., islets of fibrosis presenting the appearance of a pipe-stem thrust through the liver substance involving the portal areas and not the hepatic veins. It is not the worm that harms the patient so much as the eggs, and Professor Ferguson's specimens showed that the sexually mature worm migrates from the subserous layer of the viscus and deposits its eggs in or upon the mucous surface. Apropos of the polypoid growths produced by the bilharziasis, it was interesting to see, in an exhibit shown by Professor J. M. Beatty (Sheffield), that a sporozoon (the precise nature of which could not be determined) was capable of producing an anal polypus in a patient from India.

Space prevents our referring to more than a few of the many excellent exhibits. A series of brains and cords illustrating cerebro-spinal meningitis were shown by Professor Robert Muir (Glasgow) and Professor Symmers, drawings of motile filaments in the cerebro-spinal fluid by Dr. Frank C. Eve (Hull), and an interesting series of cerebral tumours shown by Dr. T. Grainger Stewart (London), deserve mention. In the domain of gynæcology Mr. E. H. Shaw and Dr. R. V. Solly showed examples of that curious condition syncytioma malignum, and Dr. Cuthbert Lockyer the results of Wertheim's abdominal hysterectomy. In point of artistic merit and method of preparation nothing could be better than the series of subserous fibroids of the uterus, fibroids and carcinoma of the uterus, and fibroid cysts with inflamed appendages, with chronic metritis and other complications shown by Professor Strassmann (Berlin). These we imagine were mounted in gelatine; the arrangement of the parts and the oval or watch-glass front admirably revealed the characteristics of the diseases and preserved the colours of the tissues. The pathology and surgery of the gall-bladder were well illustrated by a series of 63 specimens exhibited by Mr. J. Bland-Sutton (London), Mr. B. G. A. Moynihan (Leeds), Mr. G. A. Wright (Manchester), and others. A series of seven specimens illustrating cirrhosis of the liver, associated with primary carcinoma, was shown by Professor Muir, who also included a specimen showing one of the consequences of neglected appendicitis—namely, necrotic areas in the liver due to a highly septic portal pyæmia supervening on appendicitis. Those who make post-mortem examinations only at long intervals in their practice would have been pleased to see the numerous small (sponge-like) cavities which may be produced in the liver by the bacillus aërogenes capsulatus in another specimen shown by this gentleman. Dr. William Hunter (London) exhibited a series of specimens illustrating his well-known views of the origin of pernicious anæmia in gastro-intestinal sepsis and consequent hæmolysis. His specimens showed, as he has elsewhere pointed out, that the inflammatory condition of the alimentary canal is overlooked on account of the bloodlessness of the gastric and intestinal walls. In this series were included also several tongues taken from subjects of pernicious anæmia, showing the rawness and denuded condition of the tongue which he mentions amongst the earliest symptoms of the disease.

Dental surgery was unusually well represented in this year's museum. The microscopic specimens and cultures of various spirilla and bacilli found in the mouth (Mr. K. W. Goadby); irregularities of teeth in man and animals (Mr. J. F. Colyer); tumours of the jaw (from University College, Bristol); and specimens illustrating dental diseases in children (from the Royal Dental Hospital, London) were all well worthy of study. Apropos of dental surgery, one of the magnificent series of x ray photographs shown by Mr. E. W. H. Shenton had a practical bearing of the highest importance. Facial neuralgia is one of the most troublesome maladies which we are called upon to treat, and in a case of this kind a radiogram had revealed the presence of stumps, hitherto unsuspected, imbedded in the lower jaw; upon removal of these the patient after years of suffering was completely relieved.

Messrs. Leitz of Wetzlar and London kindly lent 75 microscopes, most of which were fitted with a rack-and-pinion fine adjustment. This novelty may or may not prove to be advantageous but the excellence of the lenses was quite up to the high standard of these well-known optical instrument makers.

We cannot close this notice without mentioning that Mr. Jonathan Hutchinson, sen., was an exhibitor and a constant visitor to the museum. It was Mr. Hutchinson who founded this Annual Museum over five-and-thirty years ago and he must have been very pleased with the effort this year at Exeter. Several of the coloured sketches which he exhibited illustrated melanotic lentigo of the lips and mouth, a condition which Mr. Hutchinson believes may be a "family disease" allied to that lethal disorder lentigo juvenalis maligna (xeroderma pigmentosum). The collection of so many apparently bald facts in one place often evokes the criticism of *cui bono* from those who do not remember that no carefully and truthfully recorded fact is ever quite lost. Counting the stars might seem to be a profitless proceeding, nevertheless it was the minute and patient records of the heavenly bodies made by Bradley and Groombridge in the eighteenth and nineteenth centuries which have recently enabled the astronomers of the present day to deduce several important facts and amongst others that one set of stars moves one way and another set in another direction. Minute, truthful, and patient observations still remain the basis of all scientific progress.

upwards to 1·3 per 1000 in Birkenhead, in Liverpool, and in Sunderland, 2·3 in Bootle, 2·6 in Sheffield, and 3·1 in Aston Manor. The deaths from whooping-cough, which had been 85 and 92 in the two previous weeks, increased during the week to 99, the death-rate from this disease being 1·2 in Wigan and in Gateshead, 1·4 in South Shields. 1·5 in Grimsby, 1·8 in Bury, and 3·0 in Great Yarmouth. The fatal cases of measles declined during the week to 84, having been 94 and 102 in the two preceding weeks; this disease was most fatal in Cardiff, where 20 deaths, equal to a rate of 5·6 per 1000, were registered. Scarlet fever caused a death-rate of 1·0 in Wolverhampton; but the mortality from diphtheria or from "fever" was not excessive in any of the large towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had increased from 2658 to 3669 in the 15 preceding weeks, had further risen to 3687 at the end of the week; 440 new cases were admitted during the week, against 419, 466, and 430 in the three preceding weeks. One case of small-pox was admitted and remained under treatment at the end of the week. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 139 and 129 in the two previous weeks, further declined to 97 in the week under notice, and were 20 below the corrected average number in the corresponding period of the five years 1902–06. The causes of 38, or 1·1 per cent., of the deaths in the 76 towns during the week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 50 other of the 76 towns; the highest proportions of uncertified deaths were registered in Liverpool, Manchester, Birmingham, Sheffield, Gateshead, and Reading.

In 76 of the largest English towns 8455 births and 3617 deaths were registered during the week ending August 31st. The annual rate of mortality, which had been equal to 11·8 and 11·5 per 1000 in the two preceding weeks, rose again to 11·8 in the week under notice. During the past nine weeks of the current quarter the death-rate in these towns has averaged 12·0 per 1000, the rate in London during the same period being 11·9 The lowest death-rates in the 76 towns last week were 2·0 in Burton-on-Trent, 2·1 in King's Norton, 5·2 in Hornsey, and 5·9 in Tottenham and in Devonport; the highest rates were 17·8 in Hastings, 17·9 in Walsall, 18·7 in Sunderland, and 22·9 in Tynemouth. The 3617 deaths in the 76 towns were 74 in excess of the number in the previous week, and included 437 which were referred to the principal epidemic diseases, against 378, 407, and 432 in the three preceding weeks; of these, 194 resulted from diarrhœa, 76 from whooping-cough, 73 from measles, 36 from diphtheria, 35 from scarlet fever, and 23 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic disease was registered last week in Croydon, Brighton, Plymouth, Southampton, or in ten other of the 76 towns; the annual death-rate from these diseases, however, ranged upwards to 3·1 in Bootle, 3·4 in St. Helens, 3·7 in Sheffield, 3·8 in Tynemouth, 4·3 in Walsall, and 4·7 in Cardiff. The deaths from diarrhœa, which had risen uninterruptedly in the seven preceding weeks from 39 to 165, further increased to 194 last week; the highest death-rates from this disease were 2·2 in Walsall, 2·3 in St. Helens, 2·9 in Sheffield, 3·0 in West Bromwich, and 3·1 in Bootle. The fatal cases of whooping-cough, which had been 85, 92, and 99 in the three previous weeks, declined again to 76 in the week under notice, the death-rates from this disease ranging upwards to 1·1 in St. Helens and 1·5 in Stockport. The deaths from measles, which had been 102 and 84 in the two preceding weeks, further fell to 73 last week and caused a death-rate of 1·3 in Coventry, 1·4 in Merthyr Tydfil, 2·1 in Ipswich, and 3·9 in Cardiff. The 36 fatal cases of diphtheria were slightly fewer than the numbers in other recent weeks, the greatest proportional mortality being 1·3 in Reading and 1·9 in Tynemouth. The deaths from "fever," which had been 22 and 17 in the two previous weeks, rose again to 23 last week; the highest death-rate from this cause was 1·2 in Wigan. Scarlet fever was not excessively fatal in any of the 76 towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals and the London Fever Hospital, which had increased from 2658 to 3687 in the 16 preceding weeks, had further risen to 3737 at the end of last week; 557 new cases were admitted during the week, against 466, 430, and 440 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory system, which had been 139, 129, and 97 in the three preceding weeks, rose again to 129 in the week under notice, and slightly exceeded the corrected average number for the corresponding period of the five years 1902–06. The causes of 31, or 0·9 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, and in 56 other of the 76 towns; there were seven uncertified deaths in Liverpool, three in London, three in Huddersfield, and two each in Manchester, Birmingham, Nottingham, South Shields, and Handsworth (Staffs.).

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·8 and 12·6 per 1000 in the two preceding weeks, rose again to 12·8 per 1000 in the week ending August 24th, and was 1·3 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 8·7 in Leith and 10·1 in Edinburgh, to 14·0 in Glasgow and 15·0 in Perth. The 443 deaths in these towns showed an increase of seven over the number in the previous week, and included 65 which were referred to the principal epidemic diseases, against 75 and 52 in the two preceding weeks. These 65 deaths were equal to an annual rate of 1·8 per 1000, which exceeded by 0·5 per 1000 the mean rate during the same period from the principal epidemic diseases in the 76 large English towns; they included 22 which were referred to whooping-cough, 21 to diarrhœa, eight to diphtheria, seven to "fever," five to measles, two to scarlet fever, and not any to small-pox. The deaths from whooping-cough, which had been 30 and 18 in the two previous weeks, rose again in the week under notice to 22, of which 11 occurred in Glasgow, four in Edinburgh, three in Greenock, and two in Paisley. The fatal cases of diarrhœa, which had been 21, 22, and 15 in the three preceding weeks, increased again to 21 in the week ending August 24th, and included twelve in Glasgow, three in Dundee, and two in Paisley. The deaths from diphtheria, which had been four, two, and one in the three preceding weeks, rose again during the week to eight, of which four were registered in Glasgow and three in Dundee. The fatal cases of "fever," which had been 13 in each of the two previous weeks, declined to seven in the week under notice, and included five in Glasgow, and one in Edinburgh; of these deaths three in Glasgow and the one in Edinburgh were from cerebro-spinal meningitis. The fatal cases of measles, which had been six, six, and four in the three preceding weeks, were five in the week mentioned, and included three in Glasgow and two in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 68, 55, and 48 in the three preceding weeks, rose again to 53 in the week under notice, and slightly exceeded the number in the corresponding period of last year. The causes of 14, or 3·2 per cent., of the deaths in the eight towns during the week were not certified; in the 76 English towns the proportion of uncertified deaths did not exceed 1·1 per cent.

The annual rate of mortality in eight of the principal Scotch towns, which had been 12·6 and 12·8 per 1000 in the two preceding weeks, further rose to 13·7 per 1000 in the week ending August 31st, and was 1·9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·5 in Aberdeen and 12·8 in Glasgow to 16·1 in Greenock and 16·7 in Dundee. The 475 deaths in these towns exceeded by 32 the number in the previous week, and included 62 which were referred to the principal epidemic diseases, against 52 and 65 in the two preceding weeks. These 62 deaths were equal to an annual rate of 1·8 per 1000, which was 0·4 per 1000 above the mean rate last week from the principal epidemic diseases in the 76 large English towns; they included 19 which were referred to whooping-cough, 19 to "fever," 15 to diarrhœa, seven to diphtheria, one to measles, and one to scarlet fever, but not any to small-pox. The deaths from whooping-cough, which had been 18 and 22 in the two previous weeks, declined again to 19 in the by the Government on the lines which the Commission has already so well laid. The question of latency may be mentioned as a single example. The Commission's work brings out, time after time, the fact that in order to produce progressive tuberculosis in the experimental animal by feeding, even when virulent strains of bovine bacilli are in question, it is necessary to see that a considerable dose of infective material reaches the alimentary tract. From this point of view it might be concluded that the occasional ingestion of small doses of tubercle bacilli in milk is comparatively unimportant. But it is maintained by many authorities, especially in France, that tubercle bacilli localised in lymphatic glands and other tissues in childhood may remain "latent" there for many years until some intercurrent disease or special conditions of adolescent or adult life cause them to take on a new activity which results in progressive tuberculosis or pulmonary phthisis. Clearly, if "latency" and all its possibilities have to be considered, a small dose of bovine virus taken with milk in childhood, although it may produce no immediate obvious effects, may yet be attended by most serious consequences. On a matter of this kind it would be possible to speculate indefinitely; the need is to put the matter to experimental proof under conditions in which prolonged investigations and systematic records are possible.

The Increase of Anthrax.

THE annual report of the Chief Inspector of Factories and Workshops for the year 1906 contains, as is usual, the report made to him by the medical inspector, Dr. T. M. LEGGE, on the industrial diseases of the year and on the steps which have been taken to bring them under control. Dr. LEGGE, of course, deals with a variety of topics, and his narrative is full of interest; but we must content ourselves to-day with calling attention to his account of the increased prevalence of anthrax among workers engaged in the manipulation of hides, hair, wool, bones, and other products of possibly diseased animals. In 1905 there were in this country 59 cases of anthrax, with 18 deaths; and in 1906 these numbers rose respectively to 67 and 22, the highest recorded in any year since notification became compulsory in 1896. Dr. LEGGE calls attention to the excellent work that is being carried on by the Anthrax Investigation Board of Bradford and declares that the close investigation of individual cases by Dr. F. W. EURICH, bacteriologist to the board, with reference to diagnosis, to the nature of the material upon which the infected person had worked, to bacteriological examination of suspected material, and to experimental inquiry as to the possibility of so treating such material as to minimise danger without interfering with fitness for manufacturing purposes, has been of "most material assistance" to the department, and is bringing certainty to bear where before there was only surmise. As one result of the Board's activity Dr. LEGGE is enabled to report the cases which occurred in the Bradford district with an amount of detail and a degree of confidence previously unattainable, and contrasting strongly with the meagreness of information regarding cases outside the sphere of the Board's influence. In "seven of the 14 cases occurring in the Bradford district the disease is said by Dr. LEGGE to have assumed the internal form, and in only one of these was there recovery after the injection of 200 cubic centimetres of Sclavo's serum. The words quoted occur in the letterpress of the report, but in the appended tables only 12 cases, of which five were fatal, are referred to the Bradford district. We cannot decide between the two statements, but the detailed tables seem the more likely to be accurate, especially as we have noticed in the report one or two examples of what appears to have been hasty proof-reading.

The question of disinfecting the materials in which the bacillus of anthrax is conveyed to the workers is being actively investigated at Bradford, and we may reasonably hope that success in this direction, by the use either of heat or of chemical agencies, will ultimately be attained. Dr. EURICH has found that a 1 per cent. solution of formaldehyde is an efficient disinfectant of bales opened under the liquid, and that this efficiency is not lost even when the liquid has been used three times. In the case of bales that had been steeped unopened disinfection was found to be imperfect on three occasions. The question derives much additional importance from an aspect of it to which attention has been called by Dr. J. SINCLAIR HOLDEN, medical officer of health of the Melford Rural District, who, in reference to the danger arising from a horse-hair workshop in his district, states that valuable cattle have died from anthrax in the immediate vicinity. Waste water from the works had been discharged through a drain into a brook which flows through meadows used for grazing. Between August, 1904, and May, 1905, four bullocks, one milch cow, and one colt having access to these meadows and to the brook died from anthrax; and in November, 1905, a fifth bullock died from the same cause. The waste water was then conveyed to a pond within a walled inclosure, and it was found after a time not only that the water in this pond was abundantly infected with anthrax bacilli, but also that they had passed by percolation through soil to another pond on the other side of the wall. If we remember the experiments of PASTEUR and the manner in which anthrax bacilli from buried carcasses were brought to the surface after a long period of time, presumably by earthworms, and communicated the disease to animals suffered to graze over the spot, we shall not view with equanimity the existence of such arrangements as those which Dr. HOLDEN describes. At the place he mentions the waste water is now conveyed to pits sunk in the middle of a field with a subsoil of gravel, and is said all to be absorbed, but we cannot think it impossible that the bacilli with which it is loaded may still assert their presence, possibly at some comparatively distant place and in some unexpected and exceedingly unpleasant manner. We should be much inclined, before permitting the absorption of the subsoil, to add formaldehyde with a sufficiently liberal hand.

The detailed tables of cases which form part of the report describe or mention the treatment in each case. In many of them "serum" is said to have been used, in some "Sclavo's serum" is specified, and the quantity and the number of administrations are mentioned. An account of Sclavo's serum was given by Dr. LEGGE in 1904 to the Bradford Medico-Chirurgical Society and a report of his paper will be found in THE LANCET of the 9th of July in that

The Volunteer Officers' Decoration has been conferred on Captain David Smart, Liverpool Bearer Company.

IMPERIAL YEOMANRY

The King's Own Royal Regiment Norfolk: Surgeon-Captain J. F. Gordon Dill to be Surgeon-Major (dated July 14th, 1907).

Surgeon-General Sir Alfred Henry Keogh, K.C.B., Director-General, Army Medical Service, has been appointed a honorary physician to the King, vice Surgeon-General A. F. Preston. Sir Alfred Keogh entered the service as a surgeon in March, 1880, and was appointed Director-General in 1904. He is a Knight of Grace of the Order of St. John of Jerusalem.

AN INTERNATIONAL SOCIETY OF UROLOGY.

To the Editors of THE LANCET.

SIRS,—We are informed by the Representative Committee of the French Association of Urology that it is intended to form an International Society of Urology upon the same lines as the International Society of Surgery and to hold the first congress in the autumn of 1908 in Paris. With this object a preliminary meeting will be held at the Necker Hospital in Paris on Oct. 8th prox., for the purpose of making the necessary arrangements, at which various Eastern and Western nations will be represented. We are requested by our French colleagues to forward to you this information.

We are, Sirs, yours faithfully,
REGINALD HARRISON,
London, August, 1907. JOHN PARDOE.

⁂ The members of the Representative Committee are the following:—For Paris: Professor Guyon (president), Professor Achard, and Professor Albarran. For Lille: Professor Carlier and Professor Chauffard. For Bordeaux: Professor Pousson. The secretary is Professor Desnos of Paris.—ED. L.

INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

To the Editors of THE LANCET.

SIRS,—With reference to the remarks of Dr. Sidney C. Lawrence in your issue of August 17th, p. 478, concerning the part played by Sunday schools (and may I add Band of Hope classes and the like) in the spread of infectious disease, I should like to say that the question was dealt with somewhat fully in my paper on the Gloucestershire experiment of 1904 which appeared as an addendum to Section II. Owing, however, to the very limited time allowed I was able to read but a brief abstract, and this point, with many others, was perforce omitted. I found little difficulty in applying to Sunday schools, &c., such measures of isolation as were considered essential in the day school; nor is this surprising when it is recalled that often enough the head teacher or one of his assistants functions as the Sunday school superintendent.

I am, Sirs, yours faithfully,
MYER COPLANS.
August 19th, 1907.

SOME PHYSIOLOGICAL EFFECTS OF HIGH-FREQUENCY CURRENTS IN DISEASE.

To the Editors of THE LANCET.

SIRS,—In answer to Dr. S. Sloan's letter in your issue of August 24th (p. 555) I am inclined to conclude from its tone that it was not criticism he desired but approbation. In your issue of June 29th (p. 1805) I clearly defined the nature and scope which my criticism was to take by stating "that it was more the physical than the physiological aspects of his article that I desired to comment on, it being self-evident that the trustworthiness of the latter was dependent upon the accuracy of the former." Dr. Sloan, when replying to this, ought then to have taken exception to the form which I intended my criticism to take, and not have waited until he found that it was not favourable to his particular conclusions. Consequently, in order to prove that his conclusions were inaccurate, it was only necessary for me to demonstrate, and this I claim to have done, the self-contradictory nature of his data, and to show that he had placed a wrong interpretation on the phenomena observed by him while experimenting. Dr. Sloan cannot take more out of a thing than he puts into it, hence it is impossible for him to get 40,000 watts out of his apparatus when it only takes 1250 watts (average). The average output of current from the secondary circuit is only 16 milliampères and not 500 milliampères, as he states. This does not take into consideration the loss which occurs by transforming, as well as by the high tension of the current and the "open circuit." These, together with what I have formerly stated, are quite sufficient reasons (without entering into the question of how these factors can be otherwise verified) for maintaining that little or no current was being passed through the body. With reference to the spinthermeter experiments, the explanation given by me regarding them is sufficiently clear to enable anyone acquainted with the subject to put the matter to a practical test and prove that resistance does not cause a drop in potential or annul voltage.

If Dr. Sloan desires to put the spinthermeter experiments to a further test in another direction I shall be pleased to send him a specially constructed vacuum tube of my own used for the production of ultra-violet rays. The tube is constructed to withstand in ordinary working a sustained current of one ampère at 100 volts (100 watts) for 20 minutes at a time at a periodicity of 360,000,000 per minute. The tube when it is working under the above conditions can be handled with perfect safety. If this tube be placed in circuit with an apparatus which has a potential of 30,000 volts and with a current of 250 milliampères and the same periodicity it can, with certain precautions, be handled with safety. Upon first consideration one would be inclined to think that it caused a fall in potential in the circuit, but this is not the case and it admits of explanation. To suit his argument Dr. Sloan first ignores, and then in turn claims in aid, the factors upon which he based his experiments, for in his letter of July 13th (p. 111) he states that I must have observed that he had not dealt in his paper with the effects of high-frequency currents according to either their quantity, quality, or voltage, but simply as high-frequency currents. Finding it impossible to reconcile the discrepancies in his data he asserts that it is merely a matter of theoretical consideration which does not admit of practical solution and states that we know what they are and can think intelligently of them. Later, however, he states that no one knows exactly what they mean.

I am asked why, if a true estimate of the physiological effects of high-frequency currents is to be obtained, I use the term "wattage." The reason is that wattage multiplied into time equals the energy which the body is subjected to or has to contend with when it is being treated or experimented upon. The changes brought about in the body, as he must know, are due to the former, based (as it should be) on definite data without which it is impossible to accurately estimate these changes, the physiological effects produced being in direct ratio to the energy used. (The idiosyncrasy of the patient naturally has to be considered.) To do this work current is used; hence the reason why the "wattage" should be computed upon an ampèrage which is based upon current. As I have previously stated, in order to set the matter at rest, let the body be subjected for, say, 20 minutes to 300 watts, the wattage being made up as follows: 60,000 volts at five milliampères; and secondly, 100 volts at three ampères; and then let a comparison be made of the records. If this be done I venture to state that it will lead to a restatement of much that has been written regarding the physiological effects of high-frequency currents upon the body.

Dr. Sloan has no reason for assuming that it was my intention to draw him into an unnecessary discussion or that I had been guilty of diverting your readers' attention from the main issue. He invokes authority to uphold his position. I would rather be an iconoclast than sit at the feet of idols. However, if he persists in invoking the aid of authorities to uphold his theories let him definitely state the physical data upon which these authorities have based their experiments. When he states that the time has could not alter either the terms or the period without an intimation to the Local Government Board, and could not appoint under the altered terms without first announcing the vacancy by advertisement. Dr. NASH refused to accept the altered appointment, but inasmuch as his term of office had expired and there was no possibility of a valid election, he consented to the urgent request of the council that he would hold office for three months at the former salary in order to give time for permanent arrangements to be made. In the meanwhile the affair has been reported to the Local Government Board and the Board has applied to the Southend council for an explanation of the grounds of its action, an explanation which so far, we believe, has not been furnished.

The local newspapers contain reports of the proceedings of the council, which throw a glaring light upon the fitness of some of the persons composing it to be entrusted with the sanitary administration of a populous district. It would be difficult to determine whether some of the speakers on the different occasions were more remarkable for the simplicity of their manners, for their ignorance of conditions important to the public welfare, or for the malevolence which they displayed towards an officer whose duties had brought him into collision with themselves or their friends. Some councillors wished to "rub in" certain considerations upon others, and it did not seem to be disputed that, as one of Dr. NASH'S supporters alleged, the medical officer of health had "prevented people who came to Southend from being poisoned by bad food," had "shown fearlessness in carrying out what is right, although it may not have suited the pockets of some here," and "had been the means of stamping out typhoid fever from the town." A continental critic 50 years ago thought that he had indicated the extreme limits of incongruity when he described the British forces in the Crimea as "an army of lions led by asses," but the incongruity is surely greater still which permits such people as the councillors who opposed the re-election of Dr. NASH to sit in judgment upon gentlemen of scientific knowledge, of education, and of integrity. We virtuously congratulate ourselves upon improvement since the time when it was said "and wretches hang that jurymen may dine"; we none the less suffer the sanitary condition of great towns, the health of the rising generation, and the physical efficiency of the race to be dependent upon the greed or the caprices of persons elected to positions of municipal authority by voters often as ignorant as themselves.

It need hardly be pointed out that the position of a medical officer of health, who devotes his whole time to his duties and is debarred from private practice, is one of peculiar difficulty and hardship, and that reasonable security of tenure is essential to the proper discharge of the duties of the post. Every conscientious medical officer of health must now be prepared for martyrdom, and a continuous supply of martyrs is not to be expected from even the most unselfish and disinterested of professions. The medical officer of health who is displaced by such a body as the Southend council loses his professional livelihood. He has no practice and probably no local connexion of a kind likely to lead to one, and although he may in time have opportunities of becoming a candidate for similar office elsewhere, the electors before whom he has to appear will possibly contain some of the same type as those who have dispensed with his services elsewhere, and they will be little likely to regard the conscientious discharge of duty in the past as a recommendation for the future. TALLEYRAND'S famous injunction to the clerks of the French Foreign Office, "Surtout, messieurs, pas de zèle," will become the customary advice of medical officers of experience to those who desire to engage in their branch of the profession, unless before long some adequate guarantee of safety in the discharge of duty be conferred upon them. Boards of guardians long ago gave conclusive evidence of their unfitness to be intrusted with the dismissal of medical officers under the Poor-law, and were deprived of the power accordingly, with great advantage alike to the medical profession, to the poor, and to the public. But the time has clearly arrived at which the caprices of municipal bodies should be subjected to independent and impartial control. The present President of the Local Government Board has on many occasions displayed an eminent degree of impartiality and independence of mind, and there are few ways in which he could more advantageously signalise his term of office than by the introduction of a measure for extending adequate protection to the officers upon whose reports his department is so often called upon to act. To render such a measure complete, it should also be enacted that any councillor, or other municipal authority, who was convicted of an offence against the laws which it was part of his duty to administer should forfeit his official position and should, for some specified time, be ineligible for re-election. By such a provision, and, we fear, by such a provision only, the councillor who seeks office for the purpose of practising adulteration with impunity, or for the protection of insanitary property, would be gradually eliminated from the bodies of which he is at present a dangerous and numerically not an inconsiderable element.

Annotations.

"Ne quid nimis."

THE EARLY NOTIFICATION OF BIRTHS.

THE Early Notification of Births Bill has become an Act in circumstances which will provoke much comment. As to the utility of such a measure there can be no question and members of the medical profession were amongst the first to call attention to the great good which is likely to follow on its adoption. It is unfortunate, therefore, from this point of view that the Act has not been made compulsory on all county councils to adopt. Although we cordially approve of the principle of this measure and agree that adequate steps cannot be taken to preserve the life of children of whose very existence the local authorities only too often are quite ignorant, yet we are far from approving of the manner in which it is proposed that the necessary notification shall be carried out. It has been made incumbent, failing notification by the father, that whoever may be in attendance on the mother at the time of the birth, whether it be a midwife or a medical man, shall undertake this duty. Not only this but it is further enacted by the Act that a penalty shall be imposed for any failure to carry out such notification. No one, not even the most a wooden spoon and kept in a cool place in a jug with the lid off. One breakfast-cupful may be given every three hours warmed to 37° C. (99 7° F.) according to the age of the child.

The half-hour boiling includes the time the saucepan is on the fire, which should be a brisk one; the actual boiling is therefore about 20 minutes. Children will often digest and thrive on this food when on no other. At first they do not like it, as it tastes nasty, but this passes off after they have had to take it a few times. A change in the green slimy stools is noticed after a short time; they become of a natural yellow colour, the vomiting stops, the fever subsides, and the infant begins to pick up slowly. This food is much used by the Argentine and foreign doctors in the disease called in Spanish "Empacho," which is very prevalent and fatal among children under two years of age. It is also found equally useful when the symptoms of gastro-enteritis are associated with dysentery.

I am, Sirs, yours faithfully,
K. BRUCE BARNETT, M.B., F.R.C.S. Irel.,
Peking, North China, July 23rd, 1907. Major, R.A.M.C.

AN ASSOCIATION OF SHIPS' SURGEONS.

To the Editors of THE LANCET.

SIRS,—The suggestion contained in Mr. Metcalfe-Sharpe's letter to THE LANCET of August 24th *re* the formation of a Ships' Doctors' Association is one which I think merits the serious consideration of the profession. The benefits which such a society as that envisaged by Mr. Sharpe would confer upon the medical branch of the mercantile marine appear to be manifold. Those of our *confrères* who go down to the sea in ships have suffered much at the hands of the shipowner and his agents. Not the least important duty falling to such a society as Mr. Sharpe purposes to form is to acquaint the medical officer himself of his status and prerogatives—in short, the idea should supply a long-felt want.

I am, Sirs, yours faithfully,
H. B. SYMONS.
Matlock, August 26th, 1907.

TOBACCO SMOKING AND PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In your report of the discussion at the British Medical Association on tobacco smoking and phthisis you quote Dr. A. Newsholme as saying that my observations on the apparent immunity from phthisis of young persons under 22 years of age who were smokers as compared with non-smokers of the same age were fallacious, inasmuch as the vast majority of those under 22 years *did not smoke*.

Most of us who have learnt anything of vital statistics have been readers of Dr. Newsholme's book, and I should be ashamed of being such a sorry student of his as to have made a statement based on such misleading grounds. The persons whom I had noticed in the out-patient departments of the Dublin hospitals as non-smokers and suffering from phthisis were of the age of from 16 to 22 years and males. Of this class—males from 16 to 22 years—I think that it is no exaggeration to state that the vast majority smoke. If a majority of the same age who are suffering from phthisis do not smoke there is, I submit, sufficient ground for investigation as to whether tobacco smoke affects the incidence of phthisis.

To me it seems that no social habit of tuberculous patients is so remarkable as their general abstinence from tobacco. I do not imagine that a direct bactericidal effect can be the result of the inhalation of tobacco smoke, but it appears not unscientific to hold that the continued inhalation of the fumes into the respiratory tract may have such an effect on the membranes as to make it a less suitable soil for the bacillus tuberculosis.—I am, Sirs, yours faithfully,

J. C. MCWALTER,
M.A., D.P.H., F.F.P.S. Glasg., M D. Brux.,
Barrister-at-law.
Dublin, August 31st, 1907.

THE TRADE IN POISONS.

To the Editors of THE LANCET.

SIRS,—In your issue of August 17th, p. 438, under the heading "Medicine and the Law," you observed, referring to the Brinkley case: "This points to a dangerous state of affairs capable of existing in spite of the precautions prescribed by the law with a view to control the trade in poisons."

I have lately attended a case of narcotic poisoning, the patient being comatose for 48 hours. On searching I found a one-ounce bottle of chloroform (full) and a one-ounce bottle of laudanum (full), also a bottle of chlorodyne and a bottle which when full held 50 0·5 gramme tablets of veronal but which now contained but one tablet. The first two bottles bore the label of a large London "Stores" and it is conceivable that the other two came from the same place; they were ordered by post and delivered in due course, and I was informed that the patient was in the habit of receiving in this way three one-ounce bottles of chloroform per month. If, as I suppose, for I am ignorant of the wording of the Act, it is sufficient to give one's name and address *per post* instead of signing the book, then I fail to see what is to prevent anyone from obtaining as much poison as he or she pleases.

I am, Sirs, yours faithfully,
M.B. Lond.

THE TRIPPER'S LEAVINGS.

To the Editors of THE LANCET.

SIRS,—In a recent issue of THE LANCET under this heading you called attention to the hideous carelessness of some people in regard to the safety and comfort of others, instancing the habit displayed by certain trippers of leaving broken bottles in the grass near the site of an *al fresco* meal. Doubtless you had concrete examples in your mind, but here is another.

There is a golf course at Bexhill near the beach. On Saturday last I accompanied a small girl across some turf *leading up to* the golf club. I happened to be ahead and saw in the grass a smashed bottle exactly in the line where the child was just going to run. I was able to warn her. She had sandals on, which would not have protected her ankles or the side of her feet at all, and these she had only put on a minute before. The beach here is pullulating with barefeet children, any of whom might have wandered there. Your protest is a valuable one.

I am, Sirs, yours faithfully,
M.D.
Bexhill, August 29th, 1907.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Port Sanitary Authority.

AT a meeting of the Manchester port sanitary authority held the week before last Mr. W. F. Dearden reported that on June 12th a case of small-pox was found at a sailors' lodging-house, and that the patient had arrived by a vessel reaching the docks on the 6th. There were 15 persons on board, and of these three showed good vaccination and re-vaccination marks; the remaining 12 were revaccinated at once. The men were kept under observation, but there had been no spread of the disease. This incident shows the need for careful watchfulness and for all possible precautions against the introduction of infectious diseases, more especially of small-pox, the defences against it, in the present state of the vaccination question, being by no means as strong as they should be. Mr. Dearden also reported the existence of friction in connexion with the removal of condemned carcasses from the foreign animals wharf. It seems that the inspector of the Board of Agriculture first of all allowed the authority's steam launch to come alongside the wharf to take aboard the condemned meat, but later objected to this being done, referring the medical officer to the section of the Foreign Animals Order, 1903, governing the matter. Mr. Dearden did not think the regulation applicable to the using of the landing place as had been done. If condemned meat could be removed by the port authority it was difficult to understand why it could not be removed by water. It is unfortunate that anything should be allowed to interfere with the speedy and convenient removal of condemned meat. It was decided by the port authority to refer the matter to the Board of Agriculture for its ruling.—At a meeting of the authority held yesterday it was reported that during the past month two cases of enteric fever had occurred among seamen entering the port. The disease was supposed to have been contracted the chain which binds them. The ready-made cigarette is largely responsible for the enormous growth of this servitude, and to those who are conscious of having acquired an injurious habit of indulgence which they honestly are anxious to reduce, if not to abandon altogether, there is one piece of advice which we would urge upon them—we have hardly known it to fail. Let the inveterate cigarette-smoker give up the ready-made cigarette; let him buy pure paper and good tobacco; let him make his cigarette just before he smokes it; and he will find that he will smoke consequently fewer cigarettes and be all the better for it. Such a method, if honestly adopted, would make an end to the "chain" smoker who, when he has nearly finished a cigarette, immediately proceeds to light another from the expiring ember, and ends the day with an appalling consumption of 50 cigarettes or more.

THE STUDY OF EPIDEMIOLOGY.

THE study of epidemiology is not only fascinating but must be also one prolific of good results. So, much still remains to be done. Formerly in many lands, and more especially in India, outbreaks of cholera and enteric fever, for instance, were held to be due to the epidemic constitution of the air, a term aptly criticised by Dr. Billings of America as one merely expressive of ignorance. To seek for the causation of specific diseases in the air—that is to say, to try to search for the first cause of a specific disease in the air *per se*—is, of course, a futile proceeding, but, on the other hand, to study the condition of the atmosphere, of the temperature, or of the other natural conditions that form the environment of the organisms of the specific diseases—such a proceeding must be fraught with advantage. It is well known how these specific diseases occasionally burst out in aggravated form; often the reason of this can be recognised, as witness the outbreak of measles in Fiji in a population hitherto not having had experience of this affection; or the outbreak of small-pox at Leicester, of a comparatively recent date, due entirely to the foolish abstinence for years of the population from the beneficent operation of vaccination. But, on the other hand, the specific fevers may be seen to fluctuate without these or similar factors. Take scarlet fever as an example. Graves showed how in Dublin it was of a very benign type from 1804 to 1831, and then began to increase in severity, until in 1834 it assumed the form of a destructive epidemic. Considerable fluctuations in this disease have again occurred from 1859 to 1892. What are these fluctuations due to? The influence of isolation hospitals will hardly explain them. Diphtheria is another disease exhibiting these variations in virulence and prevalence, appearing at one time in widespread and fatal epidemics and at another in mere local outbreaks. In the East we are able to explain more fully the seasonal appearances of the epidemic diseases; this explanation rests on the vital peculiarities of the special organism. Thus as regards cholera extensive epidemics do not, as a rule, occur during the long dry season in the Panjab and Central Provinces of India for the reason that the cholera organism is rapidly destroyed by drying. The enteric fever organism, again, is much more able to resist drying than the cholera vibrio, and hence it is not so distinctly a seasonal disease as cholera. The study of epidemiology should include, therefore, besides the characteristics of the various specific bacteria and micro-organisms also the influence of temperature and humidity on their growth, the methods by which they are brought into the human organism, and the personal condition determining the furtherance or the decline of epidemics. Epidemiology is essentially that branch of natural history which treats of the micro-organisms to which the microbes of epidemic diseases belong. This definition emphasises the distinction between the old unreasoning aspect of epidemiology, that of the "epidemic constitution of the air," and the more enlightened modern view which, recognising the prime essential force of the micro-organisms as the originators of disease, seeks to determine the nature of the external environment influencing these organisms. Such a study as the latter must in the end reap a golden harvest.

MEDICAL EDUCATION IN THE UNITED STATES.

THE *Journal of the American Medical Association* of August 17th is the yearly educational number, and makes valuable reading for all of us who are interested in the enormously important subject of medical education. The very numerous medical schools of the United States are tabulated in alphabetical order in this issue. The total number of American medical colleges is 161. Illinois, with a population of 5,319,000, has 14 medical colleges, all of which are situated in Chicago; Missouri, with a population of 3,320,000, has 11 medical colleges, seven of which are situated in St. Louis; Nebraska, with a population of 1,000,000, has four medical colleges; while New York, with a population of about 8,000,000, has 11 medical schools, eight of which are in New York city. The total number of medical students in the United States for the year ending June 30th, 1907, was 24,276, a decrease of 928 below the year 1906 and a decrease of 1871 below the year 1905. Of this total number, 22,303 were in attendance at the regular medical schools, 1039 at the homœopathic schools, 545 at the eclectic schools, 97 in the psycho-medical, and 292 in nondescript schools. The number of medical students at the regular schools is the smallest since the year 1900, the decrease in students seeming to be at the expense of the scientific men, whose curriculum is properly standardised. The total number of graduates for the year ending June 30th, 1907, was 4980, a decrease of 384 below the year 1906, 626 below 1905, and 767 below 1904. The number of medical graduates in the United States this year is the lowest since 1890. The number graduated from the regular schools was 4591, or 250 less than in 1906. During the past year there were 928 women studying medicine in the United States, or 3·8 per cent. of all medical students, as against 3·5 per cent. in 1906. There were 211 women graduates this year, or 4·2 per cent. of all medical graduates. During the past year five medical colleges have ceased to exist, while five new ones were added to the list. Of the 161 medical schools in the United States 131 are regular schools, 17 are homœopathic schools, and the remainder are eclectic and nondescript schools. Of the 152 medical colleges in the United States which have graduates 97 are situated in cities of 100,000 or greater population, and these schools had 3730 graduates, while the 55 schools situated in cities of less than 100,000 population had 1250 graduates. The standard of medical education in the United States varies very considerably in different States, each State making its own laws in this respect. In New York State the supervision of all departments of education is in the hands of the regents of the University of the State, a body established in 1784. The regents have full control of the practice of medicine. A four-year course of high school education is required for admission to medical study and a four-year course in medicine is also required before an individual can be admitted to the examination for licence to practise. The State Board of Medical Examiners is appointed by the regents from the licensed medical practitioners of the State and the regents have the power of removing any member of this Board. There are nine medical schools which require for admission one or more years of work in a college. Of these colleges Johns Hopkins Medical School and Harvard University Medical School require a degree in arts before commencing the study of medicine. According to the was adopted by the corporation, and a sum of £300 was voted towards the expenses of the first year. It is to be regretted that at no time since this decision was arrived at has there been a pavilion entirely vacant, but rather than delay what is looked upon as a desirable undertaking the corporation has purchased a wooden building which has been used as a hospital during the past few years by Messrs. Aird while they were constructing the new Bristol docks at Avonmouth. It is anticipated that the cost per patient will not exceed one guinea weekly, in view of the fact that the establishment charges will be shared with the present hospital. In the decade 1870–79 the average annual death-rate from pulmonary tuberculosis in Newport was 2·5 per 1000, but during the past few years this rate has been reduced to 1 per 1000.

Vaccination Fees in the Clutton Union.

The public vaccinators in the Clutton union have agreed to accept the fees proposed by the board of guardians. These are 5*s.* for the first case and 2*s.* 6*d.* for other cases where the vaccination is performed in the same house within 24 hours after the first one. At the meeting at which the board discussed the question an attempt was made to reduce the higher fee to 4*s.* 6*d.*, and even 3*s.* 6*d.*, but the proposal met with very little support and the opinion was generally expressed that although the cost of administering the Vaccination Acts was greater than formerly the work of the public vaccinators had very considerably increased.

Indiscriminate Medical Relief Orders.

At the last meeting of the Weobley (Herefordshire) board of guardians Mr. R. I. Dansey, one of the Poor-law inspectors of the Local Government Board, drew attention to the too ready manner in which medical relief orders could be obtained. The union is an extensive one and the relieving officer, in order to save the time of those persons likely to apply for relief who lived at a distance, had been in the habit of giving blank orders to the persons in charge of some of the pay stations. These persons had been accustomed to receive applications for medical relief and had filled up the orders at their discretion. If this practice prevails in other unions it behoves Poor-law medical officers to see that it is discontinued. They are exploited quite sufficiently already and should not be saddled with further burdens.

The Milk Supply of the Rhondda Valleys.

It is satisfactory to find that the milk-dealers in the Rhondda valleys have decided to league themselves together with the avowed object of securing a pure milk supply. They propose to endeavour to secure a warranty with every consignment of milk instead of a yearly warranty as at present. Milk is not always diluted before it reaches the vendor, however, and one of the latter was recently fined at the Porth police court £10 for adding 30 per cent. of water to the milk he was distributing. His excuse to the magistrate before whom the case was tried was, to say the least, ingenious. He said that he sold it for pastry-making to a baker who required diluted milk.

Prosecution of an Alleged "Specialist."

At Brixham in Devonshire on August 22nd John Fee, a "machinist," of Torquay, was charged in custody "that on July 22nd last he, not being a registered medical practitioner, did unlawfully use the title of Doctor Maclaren, thereby implying he was registered under the Medical Acts." Evidence showed that the prisoner called at a house in Brixham and falsely represented that he was sent by Mr. W. J. Quicke of Brixham as a "specialist," and in consequence was allowed to see a female patient who was ill in bed. The prisoner pleaded guilty and attributed the offence to being in an intoxicated condition. The magistrates inflicted a fine of £10 or two months' imprisonment. The prosecution was conducted by the Medical Defence Union.

An Action for the Recovery of Medical Fees.

At St. Austell (Cornwall) county court on August 20th Mr. R. F. Stephens of St. Austell sued a local carrier for £12 for professional attendance. An accident happened to the defendant's wagoner and the defendant gave Mr. Stephens instructions to attend the man, adding that he would pay for the treatment. Three witnesses stated that they heard the defendant tell the plaintiff that he would pay him. For the defence it was contended that he had not employed the medical attendant, the defendant adding that the witnesses had spoken falsely as to his statement to Mr. Stephens. Judge Granger gave judgment for the amount claimed with costs, adding that the defendant had committed "most impudent perjury" and that he would consider whether it was his duty to send the papers to the Director of Public Prosecutions.

Sept. 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The West of Scotland Convalescent Homes, Dunoon.

THE thirty-eighth annual report of the Seaside Homes at Dunoon was submitted this week to a meeting of subscribers. During the year 4713 persons (exclusive of children under two years of age) were admitted to the homes and of these 4421 were restored to health, 178 were relieved, 87 did not improve, and five died. The total number of persons admitted since the homes were opened in 1869 has been 115,070. The patients come from all parts of the West of Scotland but principally from the great industrial centres of Lanarkshire and Renfrewshire. Since the last report a large addition, providing 50 beds, has been made to the buildings, thus making in all 300 beds and cribs available. The ordinary income of the institution for the year amounted to £7643 and the expenditure to £6724. The extraordinary expenditure, chiefly represented by the cost of the new wing, amounted to £5693. To meet this large outlay the invested funds were drawn upon and were thus reduced from £14,400 to £10,400. A satisfactory point about the financial statement is that of the ordinary income fully one-half was contributed by the working-classes who benefit principally by this institution. At the meeting it was pointed out by the chairman, Sir John Ure Primrose, that although much had been done in the way of providing convalescent homes for adults, very little had been done in that respect for suffering children. He suggested that the churches in various districts should coöperate and have a common convalescent home. They possessed all the machinery, and through their agencies and missions and otherwise they knew where suffering was. Thus by a little expenditure of effort and money homes could be opened for a host of little ones for whom as yet no adequate provision had been made.

Steeplejack's Terrible Death.

Last week a steeplejack met with a terrible death while engaged in his work at Glasgow. At the time of the accident he was repairing the top of a chimney stack in the chemical works of Messrs. Joseph Townshend and Co. when he fell to the ground. This chimney has the reputation of being the tallest in the world, measuring 468 feet in height, and thus the terrible nature of the man's fall may be realised. When picked up, nearly every bone in the body was broken. It is suggested that the unfortunate man may have been overcome by the fumes issuing from the mouth of the chimney.

Anthrax Outbreak in Kintyre.

A somewhat serious outbreak of anthrax has taken place in Campbeltown parish, two farms being involved. In all eight animals have been destroyed and the carcasses treated by burning.

Sept. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis in Ireland.

IN the annual report of the Local Government Board for Ireland covering the year ending March 31st, 1907, special reference is made to the present prevalence of pulmonary tuberculosis in Ireland, where in 1905 there were 12,000 deaths due to tuberculous diseases and particularly to pulmonary tuberculosis and that the death-rate from this particular form of disease stands at a far higher figure in Ireland than in either England or Scotland. The Board thinks many of the difficulties at present experienced in dealing with the problem of consumption would be overcome if power were given to county councils to establish and maintain, either singly or in combination, suitable institutions for the treatment of consumptives. They suggest a intestinal obstruction is due to stretching of the mesentery. Hence the pain is not always referred to the position of the strangulated gut. In two cases of volvulus of the sigmoid flexure Dr. Bloodgood found that the pain was referred to the region of the left kidney which corresponds to the origin of the nerves supplying the meso-sigmoid. When peristalsis takes place the pain becomes intermittent or colicky. Thus the most characteristic symptom of strangulation is sudden intense abdominal pain. If situated in the right iliac fossa it may suggest appendicitis; in the gall-bladder area, gall-stones; in the region of the kidney, renal colic. In the two cases of acute volvulus of the sigmoid flexure just mentioned the pain could not have been differentiated from that due to renal calculus, and in one it was referred to the testicle. A patient who complains of sudden abdominal pain of such intensity that he begs for relief should be examined critically and the possibility of an acute lesion demanding early operation should be considered. In the pain of strangulated ileus the shock is more marked than in that of appendicitis or of hepatic or renal calculus, but usually is not as severe as that of acute hæmorrhagic pancreatitis. The primary nausea and vomiting are not at all characteristic of obstruction and may be present in any acute abdominal lesion. In obstruction there are symptoms of shock, rapid pulse and pale face. The patient may say that he feels weak, as if he had been kicked in the abdomen, whilst the moment before the attack of pain he may have been in the best of health and strength. If the abdomen is carefully examined the localised tenderness and rigidity of early appendicitis and cholecystitis are not found but more general muscular rigidity without tenderness. Occasionally the distended loop above the strangulation can be palpated (von Wahl's sign). If this is situated in the pelvis it may be felt per vaginam or rectum. A palpable distended loop is pathognomonic of strangulation ileus, but it can be distinguished only in the early hours before general distension obliterates it. Another sign of strangulation is peristalsis. How often it can be made out cannot be said; it always is absent in the late stages when the intestines are distended. An important early sign of strangulation, first described by Cushing in Dr. Halsted's clinic in 1898, is leucocytosis. In a case of acute volvulus mentioned the count was 34,000 three hours after the onset. In obturation ileus the acute primary symptoms are frequently absent. The abdominal pain is more a general discomfort than an acute agony. Constipation first attracts attention, then distension, and then vomiting, which may in a case of delay be fæcal. If the obturation is in the small intestine peristalsis is a constant early symptom; if it is high, distension is slight or absent and fæcal vomiting is early. In obturation of the colon the distension may be extreme before vomiting takes place.

THE NEED FOR PUBLIC MORTUARIES.

Dr. Lovell Drage, the coroner for Hertfordshire, is a gentleman of extensive knowledge and of scientific caution, so that he is probably correct in the assertion which he is reported to have made, at an inquest held last week upon the body of Arthur Beaumont, to the effect that in a place where there is no public mortuary, the police are entitled to take a corpse to the private house of the overseer, and to deposit it there, in the drawing-room if they can find no place more suitable, pending the formalities which would precede interment. We are not surprised that a contemporary should speak of the coroner's announcement as embodying "a new terror to overseers," and the reported declaration of Police-Sergeant Defeher, the senior police officer at New Barnet, that in future he would "see that bodies were taken to the homes of the overseers pending inquests" reminds us of the well-known story of the commissariat officer in the Peninsula who angrily complained to the Duke of Wellington that General Picton had threatened to hang him if certain provisions were not forthcoming at an appointed place and time. The Duke sympathised, but advised the complainant to use all possible diligence because "General Picton was very likely to keep his word." Sergeant Defeher speaks as if he were not to be trifled with, and Hertfordshire overseers must clearly be prepared for the worst. With all deference to Dr. Drage we should have fancied that the provision of a mortuary was the duty of the district council or other local sanitary authority and that the overseer could not be held personally responsible for neglect, but we sincerely hope he may be right and that the law may indeed be such as to afford to overseers the strongest possible inducements for keeping sanitary authorities up to the performance of this most necessary duty. There are discrepancies between different reports of the inquest as to the nature of the place to which the body of Arthur Beaumont was actually conveyed, one report describing it as a railway tank-house, and another as "a stable infested by rats," but, even without the last-mentioned additional horror, the place was clearly unsuitable for the purpose to which it was applied. We have on many occasions spoken strongly with regard to the necessity of proper mortuary accommodation in all parishes, and, wherever the responsibility may rest, there is at least no doubt that every sanitary authority has full power to make the necessary provision. We would suggest that the houses of the chairmen of authorities in default would be even more suitable temporary resting-places for dead bodies than the houses of the overseers, and if the police have any discretion they might advantageously exercise it in the indicated direction.

THE HOME OFFICE AND FACTORY ELECTRICITY SUPPLIES.

THE Home Office has recently issued a draft copy of regulations which apply to the generation and transformation as well as the distribution and use of electrical energy on all premises under the Factory Act at pressures above 130 volts on a continuous circuit and 60 volts on an alternating circuit. Regulations were issued in 1904 having reference to the use of electrical energy at medium pressure. It was found, however, that although the requirements had been in force for some years as Board of Trade regulations many difficulties arose in regard to their enforcement under the Factory Act. In issuing the present regulations the Secretary of State, while realising that there may be danger at pressures below those we have quoted, has been guided by the fact that the serious accidents from shock which have come to his notice have been at pressures generally exceeding the limits now laid down. It appears that while in many electrical installations the utmost care has been taken to prevent unnecessary danger there are striking exceptions to this rule even in works recently carried out. In drafting the regulations the Home Office rules for the use of electricity in mines, the various Board of Trade rules, including those for the use of electrical energy at medium pressures, the rules of the Institution of Electrical Engineers, and those of the fire insurance offices have been consulted. Some of these prescribe details to a greater extent than would be possible in regulations applicable to such a wide field as now dealt with, and in many points it has been considered, in view of the rapid development of electrical engineering, more expedient to indicate broadly the dangers to be avoided and the nature of the precautions required, than to define particular means of insuring safety. The view apparently prevails that where the supply of electrical energy is at low pressure there is no danger of shock, whereas such is not the case. Fatal cases of shock at low pressures are by no means of rare occurrence. They

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

An Outbreak of Small-pox in Vienna.

AN alarming outbreak of small-pox occurred quite recently in Vienna, which, however, was soon checked, thanks to the prompt and vigorous action taken by the sanitary authorities. The primary causes of the outbreak appear to be recent immigration and the tourist season. Then the laxity with which the public is used to look upon the necessity of vaccination, together with the vaccination strike of the country practitioners who refused to accept the posts of public vaccinators at the very low rate of payment offered, were also causative factors. Moreover, it is notable that the last three years have seen a remarkable falling off in the number of vaccinations reported by the vaccination officers in spite of the slightly increasing birth-rate and the decreasing infant mortality. The crusade begun by the antivaccinationists has, however, quickly been cut short by the recent outbreak, and the people not only of the capital but also of the country have applied in large numbers for vaccination. Quite a scare came over the population when it became known that within eight days 64 cases of small-pox had been notified to the board of health and removed to the isolation hospital, whilst previously in the last ten years not more than 22 cases altogether had been seen in the town. The public vaccination offices were at once filled by hundreds of mothers with their babies. In order to deal with the urgency of the danger the authorities adopted very stringent measures. The "Epidemie Spital" used solely for epidemics of similar kind was opened at once, a strict supervision of all "suspects" and "contacts" was instituted, and the staff of the board of health has been augmented by a number of physicians who volunteered for the post as emergency physicians and vaccinators. Instructions as to the necessity of prophylactic vaccination, of absolute isolation and thorough disinfection in actual cases, together with a few words dealing with the recognition of the disease, were distributed and the population has willingly responded to the appeal from the authorities. As regards the medical aspect the disease generally runs a mild course, only three deaths having occurred till now in 64 patients. Taking the population of the city (2,000,000) into consideration the number of cases is very small, but were it not for the precautions taken undoubtedly the disease would have spread widely. So far 37 adults and 27 infants have been attacked and three infants have died. The type of the disease is the ordinary one and, as a rule, the fever is mild, so that the virulence of the supposed microbe is apparently not very great.

A Dangerous Hair-dye.

An interesting decision has been given by the Suprem Appeal Court of Austria in regard to the duties of a physician in prescribing dangerous drugs or preparations. A medical man had prepared a hair-dye and had given the sale of it to a hairdresser. But the analyst to the board of health found large quantities of copper, nitrate of silver, and antimony in the dye, and therefore the originator of the preparation was charged with negligence and punished severely. The court of appeal agreed with the judgment given by the lower court, because in prescribing drugs the use of which may be fraught with danger if used without control the physician must either control the patient himself or caution him to employ the services of another physician. Although the accused physician stated that the prescription he employed for making up this preparation was taken from a well-known author on diseases of the hair the court did not see its way to acquit him, as the sale of the dye by a non-medical man entitled the public to believe the preparation to be innocuous.

A Case of Spontaneous Gastro-cutaneous Fistula after Ulcus Ventriculi.

Cases of spontaneous fistulæ of the stomach leading to the skin have been of very rare occurrence within the last 25 years owing to improvements in surgical measures, but sometimes it happens that an ulcer of the stomach remains undiscovered and then a fistula may establish itself. Writing to the *Wiener Klinische Wochenschrift*, Dr. Mann records a case under his care of a woman, aged 40 years, who until her twenty-sixth year of age had enjoyed perfect health. Then acute pains in the abdomen began but did not prevent her from eating. She was treated in several places for hysteria and intercostal neuralgia but without much benefit; occasionally fresh attacks occurred and lasted for from eight to 14 days. There was neither vomiting nor blood in the motions. After 17 years of irregular pains the woman one day noticed a swelling in the left hypochondrium, which gradually increased in size and the skin above became red. One morning she noticed that from the centre of the swelling drops of a clear viscid liquid were escaping. In the hospital the case was thought to be osteoperiostitis of the ribs and an operation was advised. But when the skin was divided it was seen that the eighth intercostal space was open and that the escaping liquid contained particles of the patient's food. Thereupon the woman was taken to the surgical ward of the general hospital for an extensive operation. The examination of the emaciated patient at that time showed the following conditions. The edges of the wound were about two inches long, thickened, and permitted after slight stretching a view into a large cavity which was filled with a mucous liquid moving synchronously with the diaphragm. From time to time a quantity of the liquid was ejected on the wound edges; this liquid always coloured red congo paper blue. When the patient drank some water or milk it came out at once through the fistula, and the diagnosis of gastro-cutaneous fistula was established. The finger introduced into the stomach encountered much difficulty because of the shrinkage of its walls and the anterior wall was firmly fixed to the muscles and the skin of the abdomen anteriorly. No operation was performed but feeding through the mouth was stopped and rectal feeding begun. After a fortnight of this *régime*, which did the patient much good, the food was poured directly through the abdominal wound into the easily accessible pylorus and thence into the duodenum. Gradually the woman could swallow milk without losing any through the fistula. But the edges of the wound were almost always moistened by the acid liquid from the stomach and this irritation prevented closure of the wound. Cauterisation of the edges and protective ointments were of no use at all. Dr. Mann finally resolved to cover the edges and almost fill the fistula constantly with an alkaline powder, changing the constituents often so as not to irritate the wound by the powder as well. The results of this plan were excellent. The wound quickly diminished in size, the fistula got so narrow that after a few weeks only filiform bougies could be passed, and at present, although the fistula is not absolutely closed, hardly any leakage occurs. The patient is able to eat ordinary food and has gained 36 pounds in weight. She is still suffering from a hypersecretion of hydrochloric acid.

Visit of French Physicians to Austria.

A number of French physicians have recently made a tour through the most important health resorts and university cities of Austria and were received by a special committee consisting of university professors and mayors of the towns. In Vienna, after witnessing several operations at the large clinics, the scientific laboratories and the other institutes for research were visited by the guests, and a visit to the new vaccine institute terminated the excursion. The visitors took with them the impression of very exhaustive clinical work done in this city and the relations between French and Austrian medical circles will be greatly benefited by the tour.

August 27th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Death due to Nervous Exhaustion from Frequent Attendances at Spiritualistic Séances.

THE lay public as well as the medical faculty are at present much interested in the following case. A lawyer, 38 years of age, who died some two weeks ago, had enjoyed an extensive practice and was well known throughout Budapest for his charitable deeds. According to his medical man he some six years ago showed symptoms of neurasthenia, which symptoms were aggravated by attacks of religious mania. Following upon this he neglected his clients and withdrew himself altogether from public activity, while at the same time he refused to let any medical man most helpful in England and Scotland, especially in the great centres of population. We again congratulate the Women's National Health Association of Ireland on having inaugurated such an exhibition and we shall watch with great interest any further development in its progress.

THE RISKS OF MEDICAL PRACTICE.

EVERY medical man knows that both he and his fellows run daily risks of which the average layman is quite ignorant, and it is only when a startling tragedy such as recently occurred in Leeds is reported that the populace at large is aware of how a medical man takes his life in his hands, when, for example, he is dealing with a patient of unbalanced brain. Dr. Walter Clapham Hirst, a young practitioner of Leeds, was on the morning of Saturday, August 31st, shot dead at his surgery door by one of his patients named John William Harrison, who immediately after the murder committed suicide. Dr. Hirst had recently been attending Harrison whose mental condition was obviously unstable, for only two days before the tragedy a friend of Harrison received a letter from him stating that he was suffering "all through calling in that doctor who struck me on both my knees which if you will enquire brings on terrific epileptic fits." It is quite evident from this that Dr. Hirst had been testing the patient's patellar reflexes. This apparently preyed upon Harrison's mind and early on Saturday morning he called at Dr. Hirst's house, who came down to answer the night bell. Nobody saw exactly what happened, but the neighbours heard gunshots, and when they arrived they found the two bodies lying close to one another. At the inquest held on Sept. 2nd the jury found that Harrison had committed murder and had afterwards committed suicide. The jury added a rider that in their opinion there had been neglect on the part of Harrison's friends in not looking after him better. One specially sad feature of the tragedy is that Dr. Hirst had only been married for two months, and to his widow we tender our respectful sympathy in her terrible trial.

THE SOLUBILITY OF AIR IN FATS AND ITS RELATION TO CAISSON DISEASE.

THE view that the symptoms produced by withdrawing the body from high atmospheric pressure and restoring it to low or normal pressure are due to liberation of bubbles of gas is confirmed in an interesting series of experiments recorded in a paper which under the above heading we print elsewhere in our present number. The writer of the paper, Dr. Horace M. Vernon, experimented with olive oil, cod-liver oil, and lard, with the result that he found that in spite of the very different composition of these three fats the solubility of oxygen and nitrogen was practically the same, and, moreover, that this solubility is the same at temperatures of 37° C. and 15° C. respectively. It is therefore fair to assume that human fat would behave similarly and the proportion of unsaturated acids present in a fat appears to have little or no influence upon its solvent powers for oxygen and nitrogen. Taking a mean of all the values obtained with cod-liver oil and olive oil at 37° C. and with lard at 45° C., the solubility of oxygen was found to be 4·5 times greater than in water and that of nitrogen 5·3 times greater. It has been shown that blood plasma and blood dissolve distinctly less nitrogen than an equal volume of water, and hence it may be concluded that at body temperature the fat of mammals dissolves at least five times as much nitrogen as water or as blood and blood plasma. Dr. Vernon points out that the bearing of these results upon many phases of caisson disease is probably a direct one. Necropsies have shown softening of some inches of the spinal cord in the dorsal region, signs of myelitis, and irregular fissures in the mid dorsal cord, probably produced by the escape of gas. Similarly divers have exhibited necrobiosis and hæmorrhages in the spinal cord and distension of the blood-vessels by air bubbles. The injury produced on fat-containing tissues is thus explained by the ready solubility of nitrogen in the fat of these tissues, and caisson disease would appear to have its origin in the liberation of gas bubbles from these fatty tissues which occurs when the high atmospheric pressure is withdrawn. Dr. Vernon may be congratulated on having made an interesting and important note on the causation of caisson disease.

DANGER IN THE COFFEE URN.

MOST persons are familiar with the steaming urn which now is invariably to be found on the counter of refreshment-rooms, and the majority of these vessels cannot be a source of danger to the patrons of the café or restaurant, being merely open boilers, provided apparently with plenty of room for the escape of steam. While that description applies to the urn which is used for merely heating water it does not apply, it would seem, to the urn used for making coffee. The coffee urn consists of two compartments, the lower one containing the boiling water and the upper one the coffee, placed in a gauze strainer. As soon as the water boils it is forced up a narrow tube and distributed over the coffee. There is thus a more or less continuous process of hot percolation going on which is calculated thoroughly to exhaust the coffee. Doubtless the temperature of the liquid is also higher than ordinary boiling point on account of increased pressure. The vulnerable point in this apparatus is, however, the narrow tube which serves to convey the boiling water and to distribute it over the coffee. It is obvious that if this tube should get choked there would be no escape of steam and pressure would rise in the lower container until at last relief would be obtained by the urn bursting, and the result would be a miniature boiler explosion. This is not mere speculation, for a case of exactly this kind occurred recently at Bradford which unfortunately caused the death of a woman who happened to be present at the time of the explosion. Had the place been filled with customers the result would most probably have been still more serious. There is evidently danger in the coffee urn, and it seems to us that the Board of Trade might insist upon these much used appliances being fitted with some safety contrivance, or at any rate being so constructed that the great potentialities of steam in them may not be allowed to reach a dangerous point.

HÆMOLYSIS IN TYPHOID FEVER.

THAT the typhoid bacillus can form a hæmolytic substance has been demonstrated *in vitro* by E. Levy for the blood of the dog. In the course of an instructive paper by Professor M. B. Schmidt of Zürich, published in the *Centralblatt für Allgemeine Pathologie und Pathologische Anatomie* of August 15th, some interesting observations are recorded which tend to show that a destruction of red blood corpuscles can occur in the course of the disease in man. In 11 out of 13 fatal cases examined for this purpose signs of hæmolysis were discovered. In the spleen an accumulation of cells containing red blood corpuscles or hæmosiderin was found in the pulp or even free pigment masses. In the liver free hæmosiderin granules were found in the lobules, usually in the liver cells or in Kupffer's stellate cells, and occasionally in the connective tissue of the liver. Pigment was never found in Glisson's capsule. Such a deposit of pigment in the liver in young children Professor Schmidt regards as physiological, since he has repeatedly observed it in cases when there was no ground for suspecting any pathological condition of the blood, but even in children board and forwarded to the Chief Secretary for his approval. The Government propose shortly to introduce an Infant Life Protection Bill. The most important and practicable of these "suggestions," many of which are general in character, are that the services of specially trained medical women should be employed to supervise the health and living conditions of all such infants, and that the milk-supply for all boarded-out or otherwise assisted infants should receive special approval based on expert advice.

Ether Explosion in a Dispensary.

The dispensers at the Children's Hospital, Melbourne, had a sensational experience recently. One of them was engaged in preparing some syrup over a gas stove when a second noticed that a bottle of ether was leaking. He called to his companion to turn out the gas but before this could be accomplished a violent explosion occurred. Three windows in the dispensary were blown out and one of the dispensers was forced through a window into the yard. A fragment of glass was carried some distance and fell on the window of a ward some distance away, breaking it. A curious feature of the occurrence was that the bottles on the dispensary shelves were not disturbed. Fortunately no one was injured beyond the temporary scare of the occupants of the dispensary.

Sydney Medical Mission.

On July 16th Lady Fairfax performed the opening ceremony in connexion with the new buildings of the Sydney Medical Mission. The movement was started in 1900 in humble premises but has developed to such an extent as to require more adequate space. Last year 2839 persons were visited in their own homes. No fewer than 7779 were treated at the dispensary and 823 at their own homes, and eight operations were performed under a general anæsthetic. A feature of the dispensary is that patients are seen at night on Thursdays in every week and this has proved very popular.

Insanity in New South Wales.

On Dec. 31st, 1906, there were 5525 insane persons under official cognisance in New South Wales as against 5277 for the previous year—an increase of 248. The average increase for the past 20 years has been 131, so that last year's increase is excessive. In 1903 the increase was 263, but with this exception last year's total is the highest ever recorded. The inspector-general of the insane, however, states that the increase is apparent rather than real. In New South Wales the proportion of insane to the general community is 1·277; in Victoria, 1·255; in South Australia, 1·389; in Queensland, 1·272; and in West Australia, 1·516.

July 20th.

Obituary.

THOMAS WILLIAM ARCHER FULLERTON,
M.B. R.U.I., F.R.C.S. IREL.,

MAJOR, I.M.S.

THE death is announced of Major Thomas W. A. Fullerton, I.M.S., which took place at Cawnpore on August 15th. The cause of death was septicæmia contracted while performing an operation, in the course of which he pricked his finger. Major Fullerton was the son of the Rev. Alexander Fullerton of Lucan, county Dublin, and received his medical education at the old Carmichael School of Medicine and at the Royal College of Surgeons in Ireland. During his career as a student he gained the Mayne and Carmichael scholarships, besides other prizes and medals. He graduated at the Royal University of Ireland in 1890 and in 1892 he entered the Indian Medical Service, taking a high place at the competitive examination. He was stationed chiefly in the United Provinces where he greatly distinguished himself in plague work. His name appeared in the list of Coronation Honours as the recipient of the Kaisar-i-Hind gold medal for public service in India. In the campaigns on the North-West Frontier he twice took part—against the Waziris in 1894–95 and in the Malakand affair in 1897–98. In each case he received the medal and clasp. He was specially successful as a surgeon, and to qualify himself still more for his surgical work he took only a few weeks ago, when on furlough, the Fellowship of the Royal College of Surgeons in Ireland. Major Fullerton was a man of charming personality and was a general favourite with everyone with whom he came in contact. He died at the post of duty in the zenith of his manhood, leaving a widow and two sons to mourn their loss.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Alexander Hirschberg, professor of medicine in the University of Lemberg; and Dr. Theobald Kerner, a German poet, who like his father, Dr. Justinus Kerner, was both a poet and a medical man. He was 91 years of age.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Löb has been recognised as *privat-docent* of Experimental Pathology.—*Berlin:* Dr. August Hildebrandt has been recognised as *privat-docent* of Surgery and Dr. Leo Langstein as *privat-docent* of Pædiatry.—*Bonn:* Dr. Gustav Embden has been recognised as *privat-docent* of Medicine and Dr. Erich Zurhelle as *privat docent* of Midwifery and Gynæcology.—*Göttingen:* Dr. Richard Waldvogel, *privat-docent* of Medicine, has been granted the title of Professor.—*Greifswald:* Dr. Erwyn Payr of Gratz has been appointed Professor of Clinical Surgery in succession to Dr. P. Friedrich. Dr. Walter Stöckel, *privat-docent* in Berlin, has been appointed to the Professorship of Midwifery and Gynæcology in succession to Dr. Martin who has resigned.—*Groningen:* Dr. W. Schutter has been appointed Extraordinary Professor of Oto-Rhino-Laryngology.—*Heidelberg:* Dr. Schwenkenbecker of Strasburg has been recognised as *privat-docent* of Medicine.—*Kharkoff:* Dr. P. Barabasheff, Extraordinary Professor of Ophthalmology, has been promoted to an Ordinary Professorship.—*Kiel:* Dr. Wilhelm Pfeiffer has been recognised as *privat-docent* of Surgery.—*Königsberg:* Dr. Max Draudt has been recognised as *privat-docent* of Medicine.—*Moscow:* Dr. I. Alexinski, *privat-docent*, has been promoted to an Extraordinary Professorship of External Pathology.—*Prague (Bohemian University):* Dr. Anton Ostreil has been recognised as *privat-docent* of Midwifery and Dr. Ottokar Kutvirt as *privat-docent* of Oto-Rhino-Laryngology.—*Vienna:* Dr. J. Partel has been recognised as *privat-docent* of Pathological Anatomy.

A CHARITY FOR THE RELIEF OF SKIN DISEASE.—The Charity Commissioners have framed an order establishing a scheme for the future administration of the funds belonging to the charity hitherto known as the British Hospital for Diseases of the Skin, 29, Euston-road, London, N.W.. The endowments consist of £10,149 8*s.* 9*d.* Consols, yielding a gross yearly income of £253 14*s* 8*d.*, and £55 10*s.* 8*d.* in local loans stock, producing £1 13*s.* per annum. The scheme of the Commissioners provides that these and all other endowments (if any) of the charity shall be managed so as to give effect to the following principles. The money to be divided as nearly as may be into three equal parts, the same to constitute the endowments of three separate charities, to be called respectively the Charing Cross Hospital Special (Skin Diseases) Fund, the Guy's Hospital Special (Skin Diseases) Fund, and the Westminster Hospital (Skin Diseases) Fund. These funds are to be administered by the general committee for the time being of the three hospitals respectively as trustees. Subject to the payment of costs of administration and management, the yearly income of each charity is to be applied solely for the relief of persons affected with skin disease, in one or more of the following ways: (1) the maintenance of beds to be specially allotted to skin patients only, such beds to be in addition to, and not in substitution for, existing beds; (2*) the provision and maintenance of medicinal baths to be used by skin patients only; (3*) the provision of disinfecting apparatus to be used for skin patients only; and (4*) the provision and maintenance of apparatus for the cure of skin disease. No part of the income of the charities may be applied for any of the following purposes: (1) defraying the cost of buildings; (2) discharging debts incurred before the date of the scheme; (3) any purpose directly or remotely connected with vivisection or experiments upon animals; (4) pathological

Dr. Whitehouse gives notes of 14 typical cases in which iquid air was variously applied, indicating the degree of ressure, the form of application, and other important oints of the treatment. The use of liquid air is never ikely to be very extensive in dermatology. Its action ppears to be two-fold. It stimulates the part, producing a reaction, and it has an anæsthetising effect. It is possible, also, that it may have slight antiseptic power, but this is not great.

"RHEUMATOID ARTHRITIS."

IN a leading article in THE LANCET of August 17th we discussed some of the principal points in the nature and treatment of rheumatoid arthritis which were raised in the discussion opened by Dr. A. P. Luff at the recent annual meeting of the British Medical Association. But little was said in reference to the dystrophic or neural theory of the origin of the disease, although some authorities still consider it to be the correct one. It may be remembered that some six years ago Dr. P. W. Latham contributed an article to our columns maintaining that the clinical symptoms in rheumatoid arthritis furnish undoubted evidence of pathological change in the nervous centres, and recorded the results of treatment directed specially to the nervous centres which had been followed by relief. He subsequently elaborated his views in a short monograph which he published in 1905. The treatment that he recommended was continuous counter-irritation over the section of the spine corresponding to the part involved. Other observers have adopted this method with success. In the *Medical Times and Hospital Gazette* Mr. W. J. Midelton, in writing on "Rheumatoid Arthritis and its Treatment by Counter-Irritation," mentions that he is an earnest advocate of the blistering treatment recommended by Dr. Latham and refers to other practitioners who have also employed it. That the suggestion is not new is proved by the reference made by Dr. Latham to a paper which appeared in the *American Journal of the Medical Sciences* in 1831 by Dr. J. K Mitchell, entitled "On a New Practice in Acute and Chronic Rheumatism"; the means chiefly employed were blisters, setons, and cupping to the region of the spine. Dr. Latham mainly recommends counter-irritation to the side of the cervical and lumbar enlargements of the spine in the earlier stages of the disease. When the disease is advanced, the ends of the bones are enlarged, and the cartilages are destroyed the normal condition cannot be restored by this method. Nevertheless, he thinks that in chronic cases where there are from time to time exacerbations of pain and swelling in some of the larger joints the application of leeches or cupping glasses, followed by the application of blisters to the spine, is of use. These therapeutic measures seem to be worthy of a more extensive trial than they have yet received, for few diseases are more rebellious to treatment than rheumatoid arthritis.

ANTENATAL RIGOR MORTIS.

THE occurrence of antenatal rigor mortis is a matter of considerable interest, although it is probable that it occurs more frequently than would appear from the number of the recorded cases. The medical attendant immediately after the birth of the child usually is occupied with the mother and possibly the endeavours made to resuscitate a stillborn infant may overcome the rigidity which is present and these facts may lead to a failure to recognise this condition. Casper in his well-known text-book on forensic medicine stated that he had never seen an instance, but this rigidity has now been described by many competent observers and would no doubt be more often met with if it were more carefully looked for. In the *Zentralblatt für Gynäkologie* of August 17th Dr. Ulrich records a most interesting case in which antenatal rigor mortis occurred in one of twins. The mother, a primipara, was delivered spontaneously of twins, the first child being born dead and in a condition of rigor mortis. The skin was pale but there was no maceration and the fœtus preserved the normal attitude of general flexion. A further interesting point in this case was that the cord of the dead child split up on the membranes almost opposite the central point of the placenta, and from this insertion the vessels, some eight in number, spread out in a fan-like manner over the membranes. The second child was small but was born alive and lived. The labour lasted some 18 hours and unfortunately, as so often is the case, the exact time at which the child died could not be determined. It certainly appeared to be dead on the woman's admission to the hospital 12 hours before the confinement took place. The membranes had ruptured in one of the intervals between two of the ramifying vessels and no ante-partum hæmorrhage occurred. It is probable from the position of the umbilical vessels that there would have been injurious pressure on them during labour and had the child not been dead already that this would have such a result. There is no inherent reason why rigor mortis should not occur in utero and, as this case shows, it can occur in a healthy full-term child. As Ballantyne and Caruso, who have collected some 49 cases from the literature, have pointed out, the occurrence of rigor mortis is no proof of extra-uterine life and Dr. Ulrich's case shows that it is possible for a living child to be born and a dead child showing antenatal rigor mortis already well established, a combination which might well be considered as proof that the dead child had a separate extra-uterine existence.

THE Department of Public Health of Queensland in a bulletin dated July 20th states that for the week ending 12 o'clock noon on Saturday, July 20th, 1 case of plague was notified in Brisbane. The patient was a man, 18 years of age, notified on July 19th who died the same night. A further bulletin dated Saturday, July 27th, states that for the week ending on that date 1 case of plague occurred, the patient being a Kanaka, aged 21 years, who died suddenly on July 25th. A post-mortem examination proved that he had died from plague. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on August 31st states that for the week ending Thursday, August 29th, 1 case of plague was notified and no deaths from the disease.

THE second Norman Kerr memorial lecture, held under the direction of the Society for the Study of Inebriety, will be delivered by Dr. Robert Welsh Branthwaite, H.M. Inspector under the Inebriates Acts, on Tuesday, Oct. 8th, at 8.30 P.M., in the hall of the Royal Society of Medicine, 20, Hanover-square, London, W. The subject of the lecture will be Inebriety: its Causation and Control.

THE London County Council has issued an Order stating that Section 55 of the Public Health (London) Act, 1891, with respect to the notification of infectious disease, shall apply in the administrative County of London for a further period of 18 calendar months as from and including Sept. 13th, 1907, to the disease known as cerebro-spinal fever (epidemic cerebro-spinal meningitis).

A TIMELY RESCUE.—A lady visitor whilst bathing at Port Gaverne, Cornwall, was suddenly seized with faintness, and being unable to call for assistance tried to draw attention by waving her arms; she soon afterwards sank. Dr. Alfred Walker, who happened to be in the water, proceeded to the spot and succeeded in bringing the lady to the surface. She was unconscious when carried to the shore but eventually recovered.

public health administration have been kept to the front by Members in all quarters of the House.

HOUSE OF LORDS.

WEDNESDAY, AUGUST 21ST.

The Medical Inspection of School Children.

The Earl of CREWE, in moving the second reading of the Education (Administrative Provisions) Bill, explained the clause instituting the medical inspection of children attending elementary schools. He mentioned that the Board of Education was now actively engaged in forming a medical department to supervise this medical inspection. He added that it was not considered possible to make a specific grant to local authorities for the purposes of medical inspection. However, the President of the Board of Education had announced that there would be a very considerable increase in the general grant and that had to be taken into consideration when they were discussing any extra cost which would be placed on the local authorities by this new duty.

The Archbishop of CANTERBURY supported the Bill cordially and said that he hoped to see the clause with respect to medical inspection carried into vigorous effect.

The Marquis of LONDONDERRY heartily concurred with what had been said in approval of the clause relating to medical inspection.

The Bill was read a second time.

MONDAY, AUGUST 26TH.

Notification of Births Bill.

On the motion of Lord ALLENDALE the Notification of Births Bill was read a second time and was passed through its remaining stages without discussion.

HOUSE OF COMMONS.

THURSDAY, AUGUST 22ND.

Infants in Public-houses.

Mr. FIENNES asked the Secretary of State for the Home Department whether he had completed his inquiries into the subject of women taking their infants and young children into public-houses in London and the large towns; and, if so, whether he would lay the reports upon the table of the House.—Mr. GLADSTONE replied: I have called for and received reports upon this subject from the metropolitan police and from the police of Birmingham, Liverpool, Manchester, Leeds, Sheffield, and Bristol. The information collected is being summarised but the summary is not yet complete owing to difficulties that have arisen in satisfactorily tabulating the materials furnished.

The Supply of Diphtheria Antitoxin.

Mr. ASHLEY asked the President of the Local Government Board whether he was in a position to make any statement with reference to the supply of diphtheria antitoxin on the part of local authorities for the treatment of those who were not in a position to buy it themselves, and whether he would draw the attention of the local authorities to the power given them under Section 133 of the Public Health Act, 1875, 38 and 39 Vic., c. 55, which enabled them to provide medicine and medical assistance to the poor of their districts.—Mr. JOHN BURNS answered: I am advised that the enactment to which my honourable friend refers and a similar enactment in the Public Health (London) Act, 1891, enable sanitary authorities, with the sanction of the Local Government Board, to provide a temporary supply of diphtheria antitoxin for the poorer inhabitants of their districts and medical assistance in connexion therewith. I propose to issue a general order giving sanction to such provision by the sanitary authorities subject to suitable conditions. The order is in preparation.

The Medical Officer of Health of Southend.

Mr. COOPER asked the President of the Local Government Board whether he was in a position to state the reasons why the medical officer of health of Southend had resigned his appointment; whether this resignation was in any way due to the desire of the corporation of Southend to reduce the salary attached to this appointment; whether any reduction of salary had been sanctioned by the Local Government Board; whether the medical officer of this town had to devote the whole of his time to the duties of his office; and, if so, whether the Local Government Board would require such a salary being paid as would secure the appointment of a qualified and competent official.—Mr. JOHN BURNS replied: I do not understand that this officer resigned his appointment. The period for which he was appointed expired on the 18th instant, and hence it was necessary that the appointment should be renewed or a fresh appointment made. No sanction on my part has been given to a reduction in the salary, nor had I heard anything of the subject until to-day. I have, however, this morning received a communication from the town clerk to the effect that the town council has reappointed the officer for three months at £600 a year, but that it proposes to advertise for applications for the post at a salary of £500 a year. I gather that the present medical officer declined to accept reappointment on these terms. It is intended that the person to be appointed as medical officer of health shall also act as medical superintendent of the hospitals for infectious disease and as medical officer of the education committee. Subject to this he will be required to devote the whole of his time to his duties as medical officer of health. Whether the proposals of the town council are such as I can properly approve is a matter which will receive my consideration.

Calf Lymph.

Mr. WEIR asked the President of the Local Government Board, in view of the fact that before the lymph obtained from any calf was used the animal was slaughtered for the purpose of ascertaining the condition of its health, whether he would state how many of the 505 calves hired last year were found on examination to be in perfect health; and, seeing that the hire of a four months old calf for a fortnight costs the Board on an average 34s., whether he would say if, in making arrangements for the supply of calves, the Board called for tenders, and for what period contracts were made.—Mr. JOHN BURNS furnished the following written answer: Of the 505 calves hired last year 444 were, after slaughter, examined by the veterinary surgeon and 442 were certified as perfectly healthy. The contracts are not made for any definite period. The Board has from time to time made inquiries with a view to obtaining tenders from different contractors, but it has not found persons willing to tender under the conditions which it finds it necessary to impose.

Southend Sewage Disposal.

Mr. HUGH BARRIE asked the President of the Local Government Board whether he was aware that the town council of Southend had agreed to pay the owner of the Hadleigh Bay oyster beds £500 per annum for four years or so long as the corporation (Southend) was permitted to discharge crude sewage into the estuary, the owner meanwhile working his beds; whether the Local Government Board could permit a continuance of this practice fraught with so much danger to the public health; whether he was aware that some £20,000 sterling had been spent by the town council of Southend in recent years in defending its practice of discharging crude sewage into the estuary; and whether, in both the interests of the public health and of the ratepayers, he could see his way to order a public inquiry.—Mr. JOHN BURNS replied (by written answer): I have no information as to the agreement referred to or as to the precise amount spent by the town council in defending the existing arrangements for the disposal of the sewage of the borough. It does not at present appear to me that there would be any advantage in my directing a public inquiry of the kind suggested.

Vaccination Bill.

The House considered the Lords' amendments to the Vaccination Bill.

Dr. MACNAMARA (Parliamentary Secretary to the Local Government Board) explained that the Bill when it left the House of Commons contained a provision that either parent of a child in order to obtain exemption for him or her from vaccination should, within four months of birth, make a statutory declaration of conscientious objection. The House of Lords had so altered the Bill as to rest the obligation of making the statutory declaration on the father or the single parent having custody of the child. There was danger of imperilling the passing of the Bill if the Lords' amendment were not accepted. He appealed to the House to accept it.

Mr. LUPTON, Sir WILLIAM COLLINS, and Mr. LEHMANN regretted the attitude of the Lords on this point.

Mr. JOHN BURNS pointed out that even with the Lords' amendment the facilities provided by the Bill for making a statutory declaration by an objector to vaccination were an improvement beyond all comparison with the conditions which at present existed. On the merits of the question his own view was that the liability and responsibility should rest upon the father of the child and not upon the mother.

The House agreed to the Lords' amendments.

FRIDAY, AUGUST 23RD.

Notification of Births Bill.

The House took up the consideration on report of the Notification of Births Bill, which was amended in several respects by one of the Standing Committees. Some time ago Sir HENRY CRAIK, Sir JOHN TUKE, and Sir HENRY KIMBER placed motions on the notice paper for the recommittal of the Bill for the purpose of having deleted from it the provision that medical practitioners should be compelled to furnish the notification in question. These motions, however, were either withdrawn or were not moved.

The House at once proceeded to the consideration of Clause 1, the main provisions of which are as follows:—

"The provisions of this section shall have effect in the area of any local authority in which this Act is adopted by that authority in accordance with the provisions of this Act—

(1) In the case of every child born in an area in which this Act is adopted it shall be the duty of the father of the child, if he is actually residing in the house where the birth takes place at the time of its occurrence, and of any person in attendance upon the mother at the time of, or within six hours after, the birth, to give notice in writing of the birth to the medical officer of health of the district in which the child is born, in manner provided by this section.

(2) Notice under this section shall be given by posting a prepaid letter or postcard addressed to the medical officer of health at his office or residence, giving the necessary information of the birth within thirty-six hours after the birth, or by delivering a written notice of the birth at the office or residence of the medical officer within the same time; and the local authority shall supply without charge addressed and stamped postcards containing the form of notice to any medical practitioner or midwife residing or practising in their area, who applies for the same.

(3) Any person who fails to give notice of a birth in accordance with this section shall be liable on summary conviction to a penalty not exceeding twenty shillings: Provided that a person shall not be liable to a penalty under this provision if he satisfies the court that he had reasonable grounds to believe that notice had been duly given by some other person."

Mr. BERTRAM moved an amendment to alter the clause in such a manner that there would be no responsibility cast upon the midwife in attendance to notify the birth. Was it wise, he asked, to lay this new obligation upon women, many of whom were illiterate and had sufficient duties already to perform?

Dr. MACNAMARA, in resisting the amendment on behalf of the Government, said that if it were carried and the father of a child were absent at the time of the birth, there would be no notification of it at all. Midwives already notified births under the Midwives Act, and as they were to be supplied with prepaid letters or postcards for the purpose of the present Bill he did not think that a very serious new obligation was being imposed on them.

The amendment was negatived after some discussion.

Lord ROBERT CECIL moved an amendment to relieve medical practitioners from the obligation to notify births at which they attended. The clause laid this duty on "any person in attendance upon the mother at the time of, or within six hours after the birth." He regretted to have to move the amendment. The medical profession felt that the Bill as it stood would impose upon them a new professional duty without any payment. He believed that it would risk the success of the measure if a fee were permitted to be paid. He would point out to honourable Members that the medical profession had withdrawn their opposition to the Bill on the terms that this amendment was mucous membrane into the nearest glands, leaving no trace of their passage. Furthermore, "it has been conclusively shown that tubercle bacilli which have been ingested may within a very short time find their way into the lungs, where they set up tuberculous lesions; pulmonary tuberculosis so induced may or may not be accompanied by lesions in the mucous membrane of the alimentary tract, or glands in connexion with it." The bronchial glands were found almost invariably to become affected *after* the lungs; in none of the experiments was there any evidence that the reverse had occurred. Different species of animals differ in regard to the anatomical lesions produced as a result of feeding with bovine tubercle bacilli. In the chimpanzee and various species of monkeys the mucous membrane of the alimentary tract is specially liable to infection and tuberculous ulceration; the tonsils, though not so liable to infection as the intestines, were frequently attacked, and in several instances entirely destroyed by caseation. The associated lymphatic glands in the case of either infection always become enlarged and caseous and frequently suppurate. In pigs, on the other hand, the intestinal mucous membrane often escapes infection; when local lesions appear they are usually few and inconspicuous. The tonsils and pharyngeal mucous membrane are more frequently affected than the intestines, and the glands in the neck are usually more extensively tuberculous than the glands of the mesentery. The bronchial and portal glands become tuberculous after the lungs and liver. In some pigs infection by feeding may be followed by a tuberculous pneumonia, but in at least one instance Dr. Griffith is disposed to attribute this to accidental inhalation of the infecting material at the time when the pig was fed. Calves are much less susceptible to infection by feeding than are pigs: dogs are specially resistant, and when tuberculosis has been occasioned by feeding in dogs the lesions have usually been found in the lungs without apparent disease of the alimentary tract or glands in connection with it.

"LOATHSOME BED STUFFING."

Numerous paragraphs have appeared in The Lancet under the above heading and we continue to receive a number of letters from manufacturers of rag flock and others in which we are very generally commended for the attitude which we have taken in regard to this subject That attitude is simply an expression of concern that an obviously insanitary and filthy proceeding in connexion with the manufacture of rag flock for bedding purposes should be allowed to exist in these days of high hygienic standards. It is hard to imagine anything more offensive than the filthy rags, the offal of clothes, the worn-out dust-laden carpets which form the raw material out of which flock mattresses and many upholstered goods are made, and without the slightest attempt to submit them to a process of scientific cleaning. We write "scientific cleaning" advisedly, for it must be obvious that such material may and does mostly contain pestiferous filth which no ordinary cleaning process can destroy. Such material should be absolutely sterilised in addition to washing before it should be allowed to fill the mattress or the cushion. It must be cleansed both macroscopically and microscopically. We enjoin such measures in the light of a full and practical knowledge recently gained on this subject.

A representative of The Lancet has recently visited flock factories; he has seen for himself how offensive and disgusting this trade can be and at the same time how inoffensive it can be made, or how little exception can be taken to it on sanitary grounds, when the simple procedure of washing and sterilisation is adopted. Yet it is no exaggeration to say that the bulk of the flock made from cast-off clothing, old carpets, &c., receives no such cleansing treatment at all, it is merely worried into a flocculent material by the "devil." The fluffy substance after it leaves this powerful tearing up machine bears, of course, no sort of resemblance to the old coats, hats, dresses, carpets from which it is made and is more or less presentable to the eye when ocular examination is confined to the surface. Deeper inspection it will not bear; it is often loaded with dust and frequently has an offensive smell. Dormant as this filth may be in ordinary circumstances, it is unpleasant to think what a stimulus may be given to its disease-dealing potentialities when it is brought to the temperature of incubation and to a condition of moistness by the person who sleeps upon it. We have met not a few manufacturers who frankly acknowledge the evil, yet who are bound to confess that they are powerless to stop it because the demon of cheapness is deaf to sanitary considerations. The mattress that costs a shilling or so more because it has been thoroughly cleansed and sterilised is not regarded as better value for the money by an ignorant section of the public. If only disease entities were as obvious to the eye as, say, cockroaches, that view might be modified, and in this case a general agreement might possibly be arrived at that what was cheap was also decidedly nasty. The production of unwashed, unsterilised flock is thus thrust upon the flock manufacturer whether his views be clean and wholesome or not. He must meet a stupid, ignorant demand or lose a large part of his business.

But much to their credit there are manufacturers who detest this traffic and who, in spite of the risk of reducing the volume of their trade, have established at their factories cleanly methods and have gone so far as to provide for the complete sterilisation of the materials in an efficient steam sterilising apparatus prior to their conversion into flock in the "devil." They have gone further and have even placed the method under the control of a bacteriologist and have not been satisfied until the evidence was convincing that the material came through the process absolutely sterile as disclosed by bacteriological experiment.[1]

Of course such treatment adds to the cost of the material, but surely such a regard for sanitary considerations should be recognised and should never be allowed to be severely handicapped by the unchecked and unrestricted output of "wools" which are loathsome and filthy. Not long ago a question was put to the President of the Local Government Board in the House of Commons as to whether it was the intention of his department either by legislation or otherwise to prohibit the use of rag flock in the making of bedding without first subjecting it to some cleansing and disinfecting process. Mr. Burns replied that the compulsory cleansing of rag-flock could not be generally secured under the existing law. He was not in a position, he added, to promise legislation on the subject but "the point has been noted for consideration when a suitable opportunity offers."

It should be pointed out that the evil was well known to the Local Government Board more than 25 years ago. In the annual report of the medical officer of the Local Government Board, for example, for 1885 appears a report by Dr. H. F. Parsons "On the Manufacture of Rag Flock in Reference to the Possible Dissemination of Infectious Disease by this and other Products of Woollen Rags." Dr. Parsons states that rags are imported into this country from almost every part of the world in which people are sufficiently civilised to wear clothing. There are large consignments from the continent, while other rags are collected in this country by "marine store dealers." A very dirty class of rags is collected from the dust hills on which the refuse of London and other large towns is tipped. Woollen rags, it appears, are also used as manure, especially for hops. Rags are sometimes met with, we learn from this report, which are soiled with blood or excrement, but Dr. Parsons "did not hear of poultices being observed or anything which would lead to the inference that the rags had been used by sick persons." In recapitulating the results of his inquiry Dr. Parsons states that the rags from which the inferior qualities of flock are made are commonly very dirty and do not, as a rule, undergo any process of purification beyond the removal of dust. He recommends the disinfection or purification of rags, adding that the best disinfectant for the purpose is heat in the form of superheated steam or hot, moist air.

It is true that the law forbids under penalty the selling, transmission, or exposure of infected articles, and that if infected rags pass into the market it is through a breach of the law on the part of the original vendor. The position that some manufacturers take, therefore, is that they are not responsible for any breach of the law which others

---

[1] We may mention the names of two firms at least, who have communicated with us and who adopt the sanitary measures indicated and we are prepared to publish the names of any others who employ similar hygienic methods. The Wandsworth Flock Company of Dunt's Hill Mills, Garratt-lane, Wandsworth, not only thoroughly wash the raw materials but afterwards place them in a well-known type of high-pressure steam-steriliser. A well-known bacteriologist found that "the rags had been efficiently sterilised." Mr. T. R. Freeman, again, of Monkton Combe Mills, near Bath, has submitted to us samples of medium and cheap mattress wools "thoroughly washed and sterilised." "The rags are beaten by machinery specially adapted for the purpose," after which "the material is placed on stoves and dried at a germ destroying temperature."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bennett, H. G., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Butler, G. G., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Churchill, S., M.R.C.S., L.R.C.P., has been appointed House Physician to *Out-Patients* at *St.* Thomas's Hospital.

Dewar, J., M.B., B.S. Aberd., has been appointed Certifying Surgeon under the *Factory and Workshop* Act for the St. Margaret's Hope District of the county of Orkney.

Flitcroft, T. E., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the North Bolton *District of* the *county* of Lancaster.

Glassington, Charles W., M.R.C.S. Eng., L.D.S., has been appointed Dental *Surgeon to* the Duke of York's Royal Military School, Chelsea.

Gunn, A. B. M., M.B., M.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Westray District of the county of *Orkney*.

Lawry, Richard Coger, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer to the No. 1 District and Workhouse, Penzance.

Lawson, Thomas Cornelius, M.R.C.S. Eng., L.S.A., has been appointed a District Medical Officer by the Stratton Union, Cornwall.

Loughborough, A. L., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Mead, Francis H., M.D. Dunelm, M.R.C.S. Eng., has been appointed Medical *Officer* of Health of the city of San Diego, *California*, U.S.A.

Page, C. M., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Junior Casualty Officer at St. Thomas's Hospital.

Parsons-Smith, B. T., M.R.C.S., *L.R.C.P.*, has been appointed House Physician to Out-Patients at St. Thomas's Hospital.

Pinchin, A. J. S., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed House Physician to Out-Patients at St. Thomas's Hospital.

Sankey, W. O., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Senior Casualty Officer at St. Thomas's Hospital.

Scott, Frederick R., M.B., B.S. Durh., has been appointed Medical Officer of Tynemouth Workhouse.

Smith, G. McCall, M.B., B.S. Edin., has been appointed *Certifying* Surgeon under the Factory and Workshop Act for the Strathmiglo District of the county of Fife.

Sutton, W. H. R., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed House Physician to *Out-Patients* at St. Thomas's Hospital.

Walker, S. L., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Resident House Physician at St. Thomas's Hospital.

Whitehead, C. E., M.R.C.S., L.R.C.P., *has been appointed* Resident House Physician at St. Thomas's *Hospital*.

Worthington, G. V., M.B., *B.S. Cantab.*, has been appointed Certifying Surgeon under the Factory and Workshop Act for the *Cheltenham District of* the county of Gloucester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham Infirmary.—Assistant Resident Medical Officer. Salary £104 per annum, with apartments, rations, &c.

Birmingham, Queen's Hospital.—House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

Bradford Poor-Law Sanatorium for Consumptives, Eastby, near Skipton. Resident Medical Officer. Salary £100, with rations, apartments, and washing.

Bradford Workhouse.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.

Bristol Royal Infirmary.—Resident Casualty Officer for six months. Salary £50 per annum.

Buxton, Derbyshire Devonshire Hospital.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

Cambridge, *Cambridgeshire Lunatic Asylum*, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, rising *to* £150, with board, lodging, and attendance.

Carlow District Asylum.—Resident Medical Superintendent. Salary £350 per annum and allowances.

Central London Ophthalmic Hospital, Gray's Inn road, *W.C.*—*House* Surgeon. Salary at rate of £50 per annum, with board and residence.

Central London Sick Asylum District.—First Assistant Medical Officer and Dispenser at Cleveland-street, *W.*, *and Second* Assistant Medical Officer and Dispenser at Colindale-avenue, *Hendon*, N.W. Salary of *former* £120 per annum, rising *to* £150, and *of* latter £110 per annum, with board and residence in each case.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary 100 guineas per annum. Also House Physician for six months. Salary *at rate of* £50 per annum, with board, washing, and residence. *Also Clinical* Assistant.

Eccles and District *Medical* Association.—Resident *Medical* Officer. Salary £230 per annum, with residence.

Gravesend Hospital.—House Surgeon. Salary *£*100 per annum, with board and residence.

Great *Northern Central* Hospital, Holloway.—Senior House Surgeon, Senior House Physician, Two Junior *House Surgeons*, and One Junior House Physician. Salary *of* Senior *Officers at* rate of £60 per annum and *of Junior Officers at rate* of £30 per annum, with board, lodging, and washing.

Great Yarmouth Hospital.—*House* Surgeon, *unmarried*. Salary £90 per annum, with board, lodging, and washing.

Hampstead General Hospital.—*Resident* Medical Officer. Salary £80 per annum, with board and residence.

Hemel Hempstead, West Herts Infirmary.—House Surgeon. Salary £100 per annum, with rooms, board, and washing.

Hull, Royal Infirmary.—*Honorary* Physician.

Jersey Dispensary and Infirmary.—*Resident* Medical Officer.

who, like medical men, feel it to be a hardship that persons not qualified to practise a profession should do so, or should do what is equivalent to it. The procedure which has been described must to an appreciable extent interfere with the emoluments of solicitors by introducing lay advocates where, strictly speaking, only solicitors or barristers are entitled to be heard on behalf of others, and, no doubt, abuses are possible under it. Medical men naturally and strongly resent the practising of medicine by unqualified persons, and reference to the columns of THE LANCET will show the position maintained in it, for example, with regard to druggists who prescribe and to opticians who go beyond the limits of their trade. In these circumstances medical men should sympathise and be in accord with those members of the legal profession who desire to see their professional privileges protected, even though medical men may form a small percentage of the mass of small creditors who avail themselves of the services of the debt collector. The debt collector's method as described must be, to some extent or in some instances, an evasion of the law, and, apart from questions of the stamping of documents, a doubt probably remains in each case whether the assignment is a genuine one. What all would desire to see, however, is such uniformity of practice in the courts as would render the application of the law certain and precise.

The Sale of Poisons.

The firm which trades as Boots, Cash Chemists (Southern), Limited, was summoned at the West London police court recently at the instance of the Pharmaceutical Society and fined £5 with 23*s*. costs for selling strychnine without observing the prescribed formalities. The circumstances were of a peculiar nature and the prosecution was due to the tragic sequel traceable indirectly to the defendants' conduct. A customer purchased, and was allowed to take, without having his attention called to the matter by the observance of any precautions, a bottle of Easton's syrup in tabloid form. At a later date his little son, aged 16 months, while playing got hold of the bottle, broke it, and swallowed about 17 of the tabloids, with the result that he died in half an hour. Various excuses were put forward on behalf of the defendant firm, including the statement that it was a common practice in the trade to sell such tabloids without obtaining the customer's signature in the book kept for the purpose, which, as was suggested by the prosecution, might have had some effect in preventing him in the case in question from leaving the bottle about. On behalf of the Pharmaceutical Society it was denied that such laxity was customary. The magistrate, in imposing the maximum penalty, expressed his concurrence with the view that the observance of the proper formalities was likely to impress upon a purchaser the dangerous nature of the article bought, and was of the opinion that the contravention of the Act was a grave one. The case is one worthy of careful consideration by traders of the class of the defendants.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 5th, 1829.

RUPTURE OF THE LIVER, AND OF THE EXTERNAL ILIAC VEIN, WITH LACERATED WOUND OF THE THIGH.

Thomas Wight, a stout muscular man, rather below the middle stature, was admitted into Jacob's Ward,[1] between four and five o'clock, on the afternoon of Wednesday, August the 19th, with a deep lacerated wound of the right thigh. It was stated by the friends of the patient, that he had accidentally fallen from a scaffold, in Leadenhall Market, on which he was standing at the time, in the act of painting a sky-light, and in falling had come in contact with one of the hooks in front of a butcher's stall, which penetrated the back part of his thigh, and suspended him for nearly two minutes, when the hook broke, and he fell to the ground; the distance from whence he fell to the hook was said to be ten feet, and from thence to the ground six or seven more. At the time of his admission he was exceedingly pale, and the pulse at the wrist was scarcely perceptible; he appeared, however, perfectly sensible and aware of his approaching dissolution, intimating his conviction, that he should not long survive the accident. Having immediately been placed in bed, some brandy and rum (about half an ounce of each) were administered to him, which he appeared to have some difficulty in swallowing. He did not complain of any thing further than a pain across the epigastric region. He had not been long in bed when he became restless, turned several times from side to side, and almost instantly expired.

Autopsy twenty hours after death.

The abdomen being first examined, there was found contained in its cavity a large quantity (probably about two quarts) of dark-coloured blood, in a fluid state; this being removed, on tracing the different large veins, the right external iliac was found nearly torn through, about its middle. There was a longitudinal rupture of the liver, situated on the right lobe, and extending in a line from the right extremity of the sulcus transversus to the margo obtusis; and on examining the thorax, all the cavities of the heart were found to be quite empty. It may be proper to observe, that there was no external mark of injury perceptible on the abdomen. On the thigh was a lacerated wound of the integuments, about four inches long, situated at the upper and posterior part below, and extending to the inner side of the great trochanter. On continuing the examination, it was found that the hook, having entered at this part, had passed to the inner side of the great sciatic nerve, pierced the adductor magnus muscle, and on to the fore-part of the thigh to the inner side of the femoral vessels, not having penetrated the integument at the fore-part.

We have since visited the place, and find, from eye witnesses of the accident, that the statement of the persons, who brought him to the hospital, was not perfectly correct. He was standing on a ladder, and leaning forward to reach his pot, when the ladder turned over, and precipitated him on one of the hooks, (which are full a foot in length,) on which he remained suspended a considerable time, the bystanders being so shocked that they were incapable, at first, of rendering him any assistance; but in one or two minutes he was lifted off, (the hook not having broken, as asserted by the friends,) and immediately taken to the hospital. The distance from the beam to the window measures about six feet, so that the poor fellow could not have been standing more than two feet above the hook.

---

[1] St. Thomas's Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8444 births and 3542 deaths were registered during the week ending August 24th. The annual rate of mortality, which had been equal to 11·8 per 1000 in each of the two preceding weeks, declined in the week under notice to 11·5 per 1000. During the first eight weeks of the current quarter the death-rate has averaged 12·0 per 1000, the rate in London during the same period being 11·9. The lowest death-rates in the 76 towns during the week were 5·2 in Willesden, 5·4 in East Ham, 5·6 in Leyton, and 5·7 in Southampton; the highest rates were 15·6 in Warrington and in South Shields, 15·8 in Oldham, 16·6 in Burton-on-Trent, 18·8 in Wallasey, and 21·7 in Great Yarmouth. The 3542 deaths in the 76 towns during the week mentioned showed a decline of 63 from the number in the preceding week, and included 433 which were referred to the principal epidemic diseases, against 362, 378, and 407 in the three preceding weeks; of these, 166 resulted from diarrhœa, 99 from whooping-cough, 84 from measles, 37 from diphtheria, 30 from scarlet fever, and 17 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered during the week in Blackburn, Brighton, Southampton, Hornsey, Reading, Newport (Mon.), Bournemouth, West Bromwich, or Barrow-in-Furness; the annual death-rates from these diseases, however, ranged upwards to 3·0 in Great Yarmouth, 3·2 in Handsworth (Staffs), 3·3 in Sheffield, 3·8 in Aston Manor, 3·9 in Bootle, and 6·1 in Cardiff. The fatal cases of diarrhœa, which had increased from 39 to 130 in the six preceding weeks, further rose to 166 in the week under notice; the mortality from this cause ranged

AN EXCEPTIONAL INDIAN DUST STORM.

IN India dust storms, known locally as "devils," are of common occurrence at certain seasons of the year, but fortunately these portentously named meteorological phenomena are seldom severe enough to be more than merely unpleasant. It is true that they leave behind them thick layers of an almost impalpable powder, for Indian doors and windows do not err on the side of tightness, but most old residents are satisfied that they serve a useful purpose by clearing the impurities out of the air, which certainly always does feel lighter and more refreshing after the miniature whirlwinds have spent their force. In *Indian Engineering* of June 29th, however, a dust storm is described which, but for a fortunate chance, might have been the cause of a serious disaster. On the preceding Sunday, when a train from Lucknow was approaching Sandila at about 4 o'clock in the evening, the passengers became aware of an unusual atmospheric disturbance which was moving gradually south-eastward and presented the appearance of a vast range of mountains except that its colour, a greyish brown, and the convolutions of the attendant clouds revealed its true character. The spectacle is described as magnificent, and though instruments were not at hand in the train to test the speed and momentum of the wind the violent swaying of trees in all directions and the snapping of their branches bore witness to its strength. The vast mass of dust completely obscured the landscape on both sides of the line, while its depth must also have been very great for fully ten minutes were occupied in traversing it, the darkness meanwhile being as dense as though the train were passing through a long tunnel. "It was a happy accident," continues the writer in our contemporary, "that a very heavily loaded train, well filled also with passengers, happened to be travelling north-west at the time and so caught the furious storm fore and aft and not broadside on, since it is by no means improbable that had the wind met the long chain of carriages on its flank while in motion it would have blown the train over and caused no little damage, attended most likely also with loss of life. It will be interesting to note whether this altogether unusual phenomenon found any scientific observers equipped for those further details which make occurrences instructive."

MISLEADING PRESS CUTTINGS.

IN the "Looking Back" column in THE LANCET of August 24th, 1907, p. 536, we published a quotation from THE LANCET of August 22nd, 1829, under the heading of "Adulteration of Bread" in which a charge against bakers was made of using large quantities of alum in the preparation of bread. The publication of this quotation drew from the editor of the *Baker and Confectioner* a protest of considerable warmth, but subsequently we received from him a note explaining that his letter was based on a newspaper cutting of the article in question sent by a press-cutting agency which had deprived it of the heading bearing the ancient date. The editor of the *Baker's Record* fell into the same mistake for evidently the same reason, and committed to print a long leading article on August 30th founded on the assumption that this quotation from THE LANCET of 78 years ago appeared as an editorial statement in THE LANCET of August 24th, 1907. Press-cutting agencies should be more careful, but may we not suggest that editors have some responsibilities towards each other? The editor of the *Baker's Record* might, we think, have consulted our columns before jumping to the conclusion that our knowledge of baking was so rusty.

A HINT TO INTENDING SHIP SURGEONS.

To the Editors of THE LANCET.

SIRS,—In September the emigration season to South America commences and several of the Governments there have passed stringent vaccination laws for immigrants. Extra work without any extra pay has often been demanded from ship surgeons under these laws and therefore careful inquiries should be made of the shipping companies before signing an engagement. The Employers' Liability Act has been applied to seamen since July 1st and it is advisable to inquire about this also.

I am, Sirs, yours faithfully,

BITTEN.

August 30th, 1907.

URANALYSIS.

IN our issue of July 13th a correspondent asked for a simple method of approximate quantitative estimation in urine of phosphates and inorganic and organic sulphates. Messrs. Andrus and Andrus of Holborn Viaduct, London, have sent us a small pamphlet intended to include in its scope the technique of the common clinical tests for urine as ordinarily required by the medical practitioner. The authors state that no effort has been made to include the rare or complicated tests, but we do not consider that the pamphlet gives any perfect method of estimating either phosphates or sulphates. By the instruction in the pamphlet it would only be possible to determine whether these are in diminution or in excess of the normal.

SILVER ACETATE.

IN a recent number of the *Münchener Medicinische Wochenschrift* silver acetate is recommended as a valuable substitute for silver nitrate in purulent ophthalmia of children. This salt is soluble in about 50 parts of water and cannot exert a caustic action owing to its extreme dilution. Silver nitrate, on the other hand, is very soluble in water and even when applied in a 1 per cent. solution frequently produces caustic effects. Since silver salts are acted upon by the acids in the tears, with liberation of the acid associated with the silver in the salt, the choice of a silver salt is of importance. On this account silver acetate is preferable to silver nitrate, the acetic acid being a mild acid compared with nitric acid, which may produce unpleasant consequences. In practice a 1 per cent. solution of silver acetate is dropped into the eye, which is then bathed with a physiological salt solution. Silver acetate is also recommended in gynæcological practice and is said to be less harmful and more certain than the nitrat

◆

Zagloba.—There is an infinity of books upon first aid and of these Mr. S. Osborn's, which is now in its fourth edition, is probably the best known. We give our correspondent the titles of two others which have recently appeared. "First Aid," by H. J. Collie and C. F. Wightman. London: Geo. Gill and Sons. 1903. Price 6d. "First Aid to the Injured and Sick," by F. J. Warwick and A. C. Tunstall. Bristol: John Wright; London: Simpkin Marshall. Fourth edition. 1906. A first aid class must be taught elementary anatomy and a certain amount of physiology. The former is best taught with the aid of a member of the class as a model, while the positions of the organs can be shown on a dead rabbit. We do not think that diagrams are of much value. For further information our correspondent had better write to the St. John Ambulance Association, St. John's Gate, Clerkenwell, E.C.

Workhouse Inquest.—The resident medical officer of a workhouse is not considered as entitled to a fee for giving evidence or for making a post-mortem examination even at the direction of the coroner for an inquest held upon the body of a deceased inmate. The Coroners Act of 1887 in Section 22 provides that no fee or remuneration shall be paid where an inquest is held on the body of a person who has died in the county or other asylum or in a public hospital, infirmary, or other institution, to the medical practitioner whose duty it may have been to attend the deceased person as a medical officer of such institution.

Overworked.—In the absence of any specific clause in the agreement between principal and assistant the assistant may be supposed to be required to give his whole time to the work. Of course, most principals arrange with their assistants that the latter shall have some free time, if only because no man can work properly without intervals of relaxation. In such a life as that of a busy general practitioner it is not always possible to say that these intervals shall fall on stated days or at stated hours.

Typhoo-Tipps.—The tea contained 6·30 per cent. of tannin as against 10·00 per cent., the average amount found in ordinary teas. The tannin proved to be tannic acid and not gallo-tannic acid, which no doubt appears in the coarse part of the leaf.

E. P.—Unfortunately, there is no other plan for our correspondent's patient than to go to a chest hospital having a sanatorium, where, if the case is suitable, she may be sent.

Anglo-Indian.—Our correspondent has not enclosed her name.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St.
Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.),
Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.),
Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square
(2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.),
West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free
(2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond street (3 P.M.),
St. Mark's (2.30 P.M.).

TUESDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St.
Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), West-
minster (2 P.M.), West London (2.30 P.M.), University College
(2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's
(2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat
(9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-
square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central
London Throat and Ear (2 P.M.), Children, Gt. Ormond-street
(2 P.M., Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (11th).—St. Bartholomew's (1.30 P.M.), University College
(2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross
(3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College
(2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.),
National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan
(9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), West-
minster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.),
Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.),
Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt.
Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic,
2.30 P.M.).

week under notice, and included seven in Glasgow, five in Edinburgh, and five in Paisley. The fatal cases of "fever," which had been 13, 13, and seven in the three preceding weeks, rose again last week to 19, of which 12 occurred in Glasgow, three in Dundee, and one each in Aberdeen, Paisley, Leith, and Greenock; these 19 deaths included ten from cerebro-spinal meningitis in Glasgow, two in Dundee, and one each in Aberdeen and Paisley. The deaths from diarrhœa, which had been 15 and 21 in the two preceding weeks, declined again to 15 last week, and included seven in Glasgow, three in Dundee, three in Leith, and two in Aberdeen. Of the seven fatal cases of diphtheria five occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 43 and 53 in the two preceding weeks, declined to 51 in the week under notice, and were ten below the number in the corresponding period of last year. The causes of 18, or 3·8 per cent., of the deaths in these eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 15·7 and 17·8 per 1000 in the two preceding weeks, declined again to 15·7 per 1000 in the week ending August 24th. During the first eight weeks of the current quarter the death-rate has averaged 18·7 per 1000, the rate during the same period being 11·9 both in London and in Edinburgh. The 118 deaths of Dublin residents registered during the week under notice were 15 fewer than the number in the preceding week, and included 14 which were referred to the principal epidemic diseases, against 13 and 17 in the two preceding weeks; of these, four resulted from whooping-cough, four from diarrhœa, two from measles, two from diphtheria, and two from "fever," but not any from small-pox or from scarlet fever. These 14 deaths were equal to an annual rate of 1·9 per 1000; the death-rate for the week from the principal epidemic diseases being 1·4 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had been one and three in the two preceding weeks, further rose during the week to four; the deaths from diarrhœa numbered four, against three, five, and six in the three preceding weeks; while the fatal cases of measles, which had been six, five, and seven in the three preceding weeks, declined to two in the week under notice. The 118 deaths from all causes in Dublin during the week included 33 of children under one year of age and 26 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons were slightly fewer than those in the preceding week. Four inquest cases and three deaths from violence were registered during the week; and 45, or 38·1 per cent., of the deaths occurred in public institutions. The cause of one death was not certified, the number of uncertified deaths being two both in London and in Edinburgh. The 107 deaths in Belfast included five from cerebro-spinal fever or cerebro-spinal meningitis.

The annual rate of mortality in Dublin, which had been equal to 17·8 and 15·7 per 1000 in the two preceding weeks, rose again to 18·6 per 1000 in the week ending August 31st. During the first nine weeks of the current quarter the death-rate has averaged 18·6 per 1000, the rates during the same period being 11·9 in London and 12·2 in Edinburgh. The 139 deaths of Dublin residents registered during the week under notice were 21 in excess of the number in the preceding week, and included 17 which were referred to the principal epidemic diseases, against 17 and 14 in the two previous weeks; of these, eight resulted from diarrhœa, seven from measles, and two from "fever," but not any from small-pox, from scarlet fever, from diphtheria, or from whooping-cough. These 17 deaths were equal to an annual rate of 2·3 per 1000, the death-rate last week from the principal epidemic diseases being 1·4 in London and 0·9 in Edinburgh. The fatal cases of diarrhœa, which had been five, six, and four in the three preceding weeks, rose again last week to eight; the deaths from measles, which had been five, seven, and two in the three preceding weeks, increased again to seven in the week under notice; while the two deaths from "fever" corresponded with the number in the previous week. The 139 deaths from all causes in Dublin last week included 24 of children under one year of age and 31 of persons aged upwards of 60 years; the deaths of infants showed a considerable decline, while those of elderly persons were in excess of the numbers in recent weeks. Eight inquest cases and six deaths from violence were registered; and 50, or 36 per cent., of the deaths occurred in public institutions. The causes of three, or 2·2 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths in London did not exceed 0·3, while in Edinburgh it was 2·9. The 90 deaths in Belfast included seven which were referred to cerebro-spinal fever or to cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: W. J. Colborne to the *Euryalus*; and D'Arcy Harvey to the *Argonaut*, on recommissioning. Staff Surgeons: E. O. B. Carbery to the *Sappho*; H. L. Norris to the *Arrogant*; T. D. Halahan to the *Isis*, on recommissioning; and J. O. G. Reed to the *Charybdis*, on recommissioning. Surgeons: A. la T. Darley to the *Bulwark*; W. N. Horsfall to the *Euryalus*; and C. J. Boucher to the *Argonaut*, on recommissioning.

Deputy Inspector-General T. D. Gimlette, C.B., has been promoted to the rank of Inspector-General, with seniority of July 1st. Fleet Surgeon J. J. Dennis has been promoted to the rank of Deputy Inspector-General, with seniority of July 1st. Fleet Surgeon J. W. O. Underhill has been placed on the Retired List at his own request.

ROYAL ARMY MEDICAL CORPS.

Major Ernest C. Freeman and Major Alfred Wright retire on retired pay. Major C. E. P. Fowler, assistant professor of hygiene at the Royal Army Medical College, has been appointed to inquire into the excessive prevalence of malarial fevers in Mauritius. Lieutenant-Colonel T. Daly has embarked for Karachi. Captain W. A. Ward has been appointed specialist in dermatology in the London district. Lieutenant-Colonel J. R. Forrest has been appointed Sanitary Officer, 3rd (Lahore) Division, as a temporary measure. Captain A. H. Safford has been posted to the Cambridge Hospital for duty.

Lieutenant Geoffrey Carlisle resigns his commission (dated Sept. 4th, 1907).

The undermentioned Majors retire on retired pay (dated August 28th, 1907):—Ernest C. Freeman and Alfred Wright.

INDIAN MEDICAL SERVICE.

Major W. H. Ogilvie, I.M.S., Major L. P. More, R.A.M.C., Lieutenant-Colonel M. A. Ker, I.M.S., Captain J. F. Martin, R.A.M.C., Major F. W. Gee, I.M.S., and Major A. E. Milner, R.A.M.C., have been appointed staff officers for medical mobilisation stores.

In consequence of the abolition of the commands in India the Principal Medical Officer, His Majesty's Forces in India, will in future nominate officers to command station hospitals at certain hill stations, and also at the headquarters of divisions and brigades.

Colonel P. H. Benson, I.M.S., has been appointed Principal Medical Officer, Secunderabad Brigade.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry): Surgeon-Captain S. L. Potter resigns his commission (dated July 23rd, 1907). 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: Surgeon-Major (Honorary Captain in the Army) R. Pollok is borne as supernumerary whilst holding the appointment of Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Highland Light Infantry Volunteer Infantry Brigade (dated July 12th, 1907).

The Volunteer Officers' Decoration has been conferred upon Surgeon-Major Charles Alexander MacMunn, 3rd Volunteer Battalion the South Staffordshire Regiment, and on Surgeon-Major George Hollier, 2nd Volunteer Battalion the King's (Shropshire Light Infantry).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

London District: London Companies: George Langrigg Leathes Lawson to be Lieutenant (dated June 1st, 1907). *Scottish Command*: Edinburgh Company: Lieutenant H. Wade to be Captain (dated August 6th, 1907).

Communications, Letters, &c., have been received from—

A.—Dr. E. Archer Brown, Lond.; Mr. C. E. Abbott, Roche; Messrs. Allen and Hanburys, Lond.; Messrs. R. Anderson and Co., Lond.; Abbott Alkaloidal Co., Chicago; Messrs. C. Ash, Sons and Co., Lond.; An Anxious Enquirer; Australia; *American Journal of Surgery*, New York, Managing Editor of.

B.—Mr. Alfred Bishop, Southend-on-Sea; Mr. A. Carnarvon Brown, Lond.; Major K. Bruce Barnett, R.A.M.C., Peking; Mr. A. A. Bradburne, Southport; Dr. H. Burrows, Southsea; Dr. Charles A. Bucklin, Glasgow; Messrs. J. Baker and Son, Clifton; Messrs. Boulton and Paul, Norwich.

Situations wanted: First 30 words, 2s. 6d.; per additional 8 words, 6d.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

passed for anyone to say what is the wattage that can be safely applied to the body, upon what authority does he rely? Then he goes on to assert that he would not like to be the "victim" of the experiment of having 400 watts applied to his body, while on his own showing he subjected his patients to 40,000 watts. Regarding the other points in Dr. Sloan's letter it is unnecessary for me to restate what I have already explained. However, there is one point I wish to touch upon. He stated that I answered one of the questions at the *end* of his paper. What I actually did was to deal, not with a question at the close, but with a query in the body of his paper. In the experiments he is carrying out to determine the difference in the physiological effects of currents by varying the frequencies he will no doubt see the necessity for definite data, and let me assure him he can claim no priority in the idea.

I shall be pleased to demonstrate to Dr. Sloan that five ampères at 100 volts can be passed through, or "in and out" of, the body, and I can promise him that the "victims" of the experiment will be none the worse. I can give him this assurance with the greatest confidence because I have already done it with perfect safety. Further, I shall be pleased to place every means at his disposal to test the accuracy of the experiment and, if necessary, to supply him with the "victims." I have noted what Dr. Sloan has deemed to be the necessary qualification before one can become a member of his scientific investigatory committee. Whether or not I possess this qualification it is not for me to say. The object of my criticism will have been served if attention has been directed to the danger of drawing hasty conclusions from high-frequency currents experiments, based upon data which cannot bear the test of scientific investigation.

I am, Sirs, yours faithfully,

Cardiff, August 29th, 1907. J. CUNNINGHAM BOWIE.

THE PRINCIPLES OF VACCINE-THERAPY.

To the Editors of THE LANCET.

SIRS,—I have read with great interest Sir A. E. Wright's lecture on this subject published in THE LANCET of August 17th and 24th. The illustration he gives of the value of a solution of sodium citrate 0·5 per cent. and sodium chloride 5 per cent. in dealing with certain localised morbid conditions seems to be capable of more general application. It has occurred to me that some trial of the method might be made in the case of septic infections of the uterus. The more or less complete and often long-continued cessation of the lochia in some of the more malignant forms of puerperal sepsis is well known. As the conditions in septic endometritis are to a greater or less degree—depending on the grade and mode of spread of the infection—comparable to those obtaining in the instance cited, it seems reasonable to assume that a like beneficial effect might be expected in at least some cases. The procedure at any rate could do no harm. Probably where the spread of the infection is by way of the blood-vessels—as, unfortunately, is most frequent in the case of streptococcic endometritis—we ought not to look for so favourable a result. Where, however, dissemination follows the lymph-channels a blocking of these would lead to a lessened access of serum to the mucous surface and hence a deficiency of bacteriotropic substances in the endometrium and deeper-lying tissue. Without going into details it seems possible, e.g., by elevating the buttocks, to cause some of the solution to be retained in the uterus after douching in the ordinary way. The action of the two constituent salts would here be precisely as in the case of a sinus.

I am, Sirs, yours faithfully,

London, S.W., August 25th, 1907. A. G. BANKS.

THE SEASONS AND MENTAL DISORDERS.

To the Editors of THE LANCET.

SIRS,—This question, the relations which the seasons bear to the incidence of mental disorders, one of considerable interest, was discussed in the medical journals some time ago. I regret that I am now unable to lay hands upon the particular journals in which the discussion took place, but its nature was such as to induce the desire to seek further definite facts for its elucidation. I proceeded, therefore, to analyse the admissions made into this house during the past 25 years, assigning to each the month on which the admission took place.

The results now before me show a not greatly divergent incidence in the various months. I need not give all the figures in detail; it may suffice here to say that July stands some 25 per cent. above every other month, whilst the lowest figures are recorded at the beginning and end of the year, with some exceptions. The meaning of those figures is open to a variety of interpretation, and it would be of interest to ascertain how far they are borne out by the experience of other and larger communities. As far as my own statistics are concerned, one significant fact predominates—viz., that July, which is, or which ought to be, one of the hottest months of the year, has the highest average, whilst June comes within the next column of figures.

One may not unnaturally infer from this that the restlessness and sleeplessness often induced by high temperatures, to say nothing of the bodily exhaustion produced by extreme heat, are not without their influence as factors of the increase in question, and we have only to note the frequency of mental breakdown in tropical countries for confirmatory evidence.

I am, Sirs, yours faithfully,

West Malling, Kent, August 24th, 1907. JAMES ADAM.

IMITATION NAUHEIM BATHS.

To the Editors of THE LANCET.

SIRS,—So-called imitations of the Nauheim bath are now so generally employed that it may be worth while pointing out what a difference there is between the cutaneous reaction excited by the effervescing waters of Nauheim and that yielded by water through which carbonic acid gas is merely passed or in which it is generated.

At Nauheim, and to a less extent in baths in which the gas is generated by chemical interaction, the skin becomes covered with minute globules of the gas and on emerging therefrom the subject rivals in hue with the "cardinal of the seas." On this cutaneous reaction depends in part the influence of the Nauheim baths on the circulation, and as it is practically absent when compressed carbonic gas is merely passed through the water of the bath *the value of this* popular means of aëration must be very small. The difference is well exemplified in the ordinary *gazogene*. If the water be withdrawn soon after filling, or even within the first few hours after charging, it gives off but little gas and tastes "flat," showing that a certain lapse of time is necessary for the gas to become dissolved. Futher experiment will show that passing carbonic acid through water leaves the latter virtually unchanged. Whatever therapeutical value the Nauheim bath possesses in virtue of its gaseous constituent is due to the latter being in a state of aqueous solution, ready to be set free when the solution comes into contact with the skin.

While it may be conceded that the effects of the Nauheim treatment are only in a minor degree dependent on the action of the gas, this action is lacking when the gas is merely passed through the water. To be operative the gas would require to be left in contact with the water in a cylinder under pressure for at least 12 hours before being employed.

I am, Sirs, yours faithfully,

Aix-les-Bains (Savoie). ALFRED S. GUBB, M.D. Paris.

BUTTERMILK IN ENTERIC DISEASE.

To the Editors of THE LANCET.

SIRS,—The difficulty often experienced by the practitioner in finding any food which can be retained by infants and young children suffering from acute or chronic febrile diarrhœa with vomiting, especially in warm climates, induces me to bring to the notice of your readers a preparation which has a great reputation in the Argentine Republic in cases of this kind and which I cannot find mentioned in any of the books on "Diseases of Children" at my disposal. It might be found useful in the treatment of summer diarrhœa at home. It is sterilised buttermilk, sweetened, and is prepared as follows: Fresh buttermilk is slowly boiled in an earthenware vessel for half an hour—one litre (about 35 fluid ounces) will last for 24 hours—and while gently boiling from five to six dessertspoonfuls of powdered white sugar are added. It must be continually stirred with

It may be objected to me that results are not so gloomy as my remarks would suggest. I must say they thoroughly bear out my own observations, but then, perhaps naturally, I am more likely to see the surgeon's failures than his successes. I will take, therefore, the records of the surgeons themselves. Let us take nasal asthma.

Out of 313 cases of nasal asthma[1] recorded by Hack, Hering, Lublinski, Sommerbrodt, Bosworth, and Roé, 150 are reported by these surgeons as cured and 40 others as improved. But I think we must be rather guarded in accepting these numbers; anyone acquainted with hospital statistics knows how rosily the surgeon anticipates the distant future, provided the immediate result be good. One of the authorities I have quoted—Roé—accentuates this view by pointing out that of his 35 cures 17 have remained well for more than one year; or, to put it my way, 18 of his 35 cures relapsed before the year was out. If his statement should prove true of the others then the cures would only reach 25 per cent. But let us put them at 33⅓ per cent. A method which cures for over a year one-third of the cases of nasal asthma is one which we must respect, for this result is a good one. Yet the most enthusiastic of these surgeons admit that there is one grave drawback to operative procedure: some of the cases, and not seldom some of the slighter ones, are made worse. This is a very serious objection and it is one that impresses itself most upon my mind, for it is just these which come back to the physician.

The physician's methods, if slow, ineffectual, and undramatic, have, at any rate, no such drawback. That they are slow I grant, and, therefore, to the gasping hurry of this twentieth century must seem undramatic. But I cannot admit the ineffectual. I certainly think he can claim one-third of his cases as cures of more than one year's duration. I believe he could say one-half. But it is also quite true that some which he cannot cure temporarily or permanently will speedily be cured by the surgeon. I do not think the proportion is large, perhaps 10 per cent. They are the cases where the local cause is a gross one and the constitutional enters little, if at all. I have said the physician's method has no drawback. It has, on the other hand, the great advantage of putting the patient on a healthy basis generally. Indeed, often the constitutional is the only treatment needed. Let me instance a case. A mother brought her little boy, aged four years, complaining that he daily suffered from violent attacks of sneezing which left him prostrate. I concluded that he had nasal asthma, but found he had also gastro-intestinal catarrh and nervous irritability. I did not examine his nose nor did I locally treat it, but cared for his body generally. He came again with his sneezing but little better, but I still refused to heed it and his mother took him away sorrowfully. By the next visit she had evidently come round to my view, for she said nothing about the sneezing, contenting herself with remarking that the other symptoms were greatly improved. The tables were turned; it became my duty now to inquire minutely after the sneezing and to find that, though he still occasionally sneezed, yet all the paroxysmal severity had vanished. Nor did it recur during the few remaining months she thought it necessary to bring him to me. But what I particularly wish to point out is, that the result was not only a better nose, but a better child altogether—body, mind, and spirit—than when he first came to me, the better nose being merely an incident in the general amelioration.

Another instance. A man, aged 42 years, came complaining of a troublesome, racking cough which kept him awake, wore him out, and was accompanied by thick yellow, blood-stained phlegm. His lungs were healthy but his pharynx was velvety, with œdematous granulations. I found he was alcoholic. His liver was firm, large, and congested; his heart was dilated and feeble; and his kidneys passed urine excessive in quantity, of low specific gravity, and with a too small excretion of proteid waste. He had slight general anasarca. I gave him some chlorate of potash lozenges to satisfy his mind but otherwise disregarded his throat, feeling sure this would recover long before his heart and moral fibre were fit to run alone. And that is what has happened. At his last visit his cough was not worth mentioning and he had hoped I should bid him good-bye, but his heart was only slightly better, though the anasarca had gone, and he still looked at me with the pitiful eyes of moral instability. So I continue to keep him in tow with threats of pharynge relapse till heart-muscle and nerve-cell are stronger.

What has all this to do with inhalation? A great deal, think. Inhalation often fails, just as operative procedur do, because we trust to it alone; and often the local disea can be remedied without the aid of either. They are bo limited in their scope, and are but the handmaids of co stitutional measures. If the lesion be gross and limited e.g., a polypus, operation is the better maid; if it be wid spread, though mild, inhalation is to be preferred. In th pointing out how limited its scope and how often it is nee less, I think I have said one-half of what I want to say (this subject of inhalation.

It is not only surgical methods which have improv during the last 40 years. The methods of inhaling ha made equal strides. Perhaps the greatest was the intr duction of atomisation which enabled us to do away with th relaxing effect of steam. Another great development the institution of inhalation chambers. If these room full of medicated air, could only be generally distributed, believe inhalation would at once take a front rank among our curative efforts. At Marlioz, close to Aix-les-Bains, is large room of this kind, some 60 feet by 30 feet, supplie with tables, chairs, and lounges, where invalids can go an chat, stroll up and down, dream in easy chairs, read boo of their own or the news of the day in the papers an periodicals on the tables, write their letters or prosecut their studies. Each half hour or so everyone is turne out to wander a few minutes in the beautiful par whilst the room is thoroughly ventilated. In this wa the patient can inhale for hours a day, withou any effort on his part, the medication necessar for his nose, his throat, his windpipe, and his lungs Allevard[2] is perhaps the headquarters of this method. A long ago as 1852 Dr. Niépce noticed that the patients use to go up to the galleries of the establishment, where th sulphuretted hydrogen was in greatest percentage, as the found the atmosphere most alleviating there. Hence i 1852 he devised inhalation rooms, both cold and hot. Ther are seven cold rooms, each 20 feet high by 20 wide by 2 long. In the centre of each is an ingenious apparatus fo forming a huge spray of the water. The sulphurette hydrogen is thus disengaged and mixes with the air. Befor being sprayed the water contains 24 volumes of sulphuretted hydrogen per 1000, but when it leaves the room it only ha 1 per 1000. The *séances* here, too, last half an hour. At their commencement there is very little H_2S in the air, but before they end this mounts up to 19 volumes in the 1000. Four other rooms of the same size are set apart for warm inhalation. There is the same central arrangement for distributing the gas. Around it the seats arise in tiers. Beneath each tier the floor is perforated and through the perforations immense volumes of H_2S vapour at from 80° to 86° F. pour into the room. Patients take off their outer garments and sit in waterproof gowns for from 20 to 50 minutes. They then rest, dressed, for from 15 to 20 minutes in a room of intermediate temperature and finally harden off in one of the cold rooms. They, in fact, give their respiratory lining membranes a sulphur Turkish bath. This seems to me to be the method of inhalation *par excellence;* I cannot see why it should not be adopted at, say, the sulphur spas of Askern, Harrogate, Llanwrtyd, and Strathpeffer. I am sure the British would take to it kindly and many would rejoice at not having to leave Great Britain. The only instance that I know of a similar installation in England is the creasote room at Brompton. Dr. Hector W. G. Mackenzie has kindly written me this description of it: "The room at Brompton is a fairly large one, about 12 feet by 16 feet and 12 feet high. The creasote vapour is produced by heating about two ounces of coal-tar creasote in a metal dish over a lamp placed on the floor. The room is made, as far as possible, air tight. The patients put on cotton overalls and wear eye-protectors. A covering is also worn passed for anyone to say what is the wattage that can be safely applied to the body, upon what authority does he rely? Then he goes on to assert that he would not like to be the "victim" of the experiment of having 400 watts applied to his body, while on his own showing he subjected his patients to 40,000 watts. Regarding the other points in Dr. Sloan's letter it is unnecessary for me to restate what I have already explained. However, there is one point I wish to touch upon. He stated that I answered one of the questions at the *end* of his paper. What I actually did was to deal, not with a question at the close, but with a query in the body of his paper. In the experiments he is carrying out to determine the difference in the physiological effects of currents by varying the frequencies he will no doubt see the necessity for definite data, and let me assure him he can claim no priority in the idea.

[1] L'Asthme d'Origine Nasale, de son Traitement par les Eaux d'Uriage. Par François Teulow-Vallo, M.D. Gustave Firmin et Montane, Montpellier, 1893.

[2] Allevard is a little manufacturing town of 3000 souls on a small branch on the south side of the main line between Chambéry and Grenoble, 1500 feet high Its water contains 2·4 volumes per cent. of sulphuretted hydrogen gas. Apart from the H_2S the water is a very pure one, in fact, it is nearly identical with the sulphur water of Llanwrtyd in Brecknockshire, a village 700 feet above the sea. Both have but little smell or taste of sulphuretted hydrogen, and both are largely drunk by the patients. But whereas at Allevard inhalation is the chief means of medication, at Llanwrtyd this means does not exist Moreover, Allevard has a theatre with a play every evening, and a very fair band plays twice a day. Llanwrtyd holds out no such attractions Allevard has sunshine, Llanwrtyd beauty. Llanwrtyd has the better baths; both have excellent hotels.

I shall be pleased to demonstrate to Dr. Sloan that five ampères at 100 volts can be passed through, or "in and out" of, the body, and I can promise him that the "victims" of the experiment will be none the worse. I can give him this assurance with the greatest confidence because I have already done it with perfect safety. Further, I shall be pleased to place every means at his disposal to test the accuracy of the experiment and, if necessary, to supply him with the "victims." I have noted what Dr. Sloan has deemed to be the necessary qualification before one can become a member of his scientific investigatory committee. Whether or not I possess this qualification it is not for me to say. The object of my criticism will have been served if attention has been directed to the danger of drawing hasty conclusions from high-frequency currents experiments, based upon data which cannot bear the test of scientific investigation.

I am, Sirs, yours faithfully,

Cardiff, August 29th, 1907. J. CUNNINGHAM BOWIE.

THE PRINCIPLES OF VACCINE-THERAPY.

To the Editors of THE LANCET.

SIRS,—I have read with great interest Sir A. E. Wright's lecture on this subject published in THE LANCET of August 17th and 24th. The illustration he gives of the value of a solution of sodium citrate 0·5 per cent. and sodium chloride 5 per cent. in dealing with certain localised morbid conditions seems to be capable of more general application. It has occurred to me that some trial of the method might be made in the case of septic infections of the uterus. The more or less complete and often long-continued cessation of the lochia in some of the more malignant forms of puerperal sepsis is well known. As the conditions in septic endometritis are to a greater or less degree—depending on the grade and mode of spread of the infection—comparable to those obtaining in the instance cited, it seems reasonable to assume that a like beneficial effect might be expected in at least some cases. The procedure at any rate could do no harm. Probably where the spread of the infection is by way of the blood-vessels—as, unfortunately, is most frequent in the case of streptococcic endometritis—we ought not to look for so favourable a result. Where, however, dissemination follows the lymph-channels a blocking of these would lead to a lessened access of serum to the mucous surface and hence a deficiency of bacteriotropic substances in the endometrium and deeper-lying tissue. Without going into details it seems possible, e.g., by elevating the buttocks, to cause some of the solution to be retained in the uterus after douching in the ordinary way. The action of the two constituent salts would here be precisely as in the case of a sions.

I am, Sirs, yours faithfully,

London, S.W., August 26th, 1907. A. G. BANKS.

THE SEASONS AND MENTAL DISORDERS.

To the Editors of THE LANCET.

SIRS,—This question, the relations which the seasons bear to the incidence of mental disorders, one of considerable interest, was discussed in the medical journals some time ago. I regret that I am now unable to lay hands upon the particular journals in which the discussion took place, but its nature was such as to induce the desire to seek further definite facts for its elucidation. I proceeded, therefore, to analyse the admissions made into this house during the past 25 years, assigning to each the month on which the admission took place.

The results now before me show a not greatly divergent incidence in the various months. I need not give all the figures in detail; it may suffice here to say that July stands some 25 per cent. above every other month, whilst the lowest figures are recorded at the beginning and end of the year, with some exceptions. The meaning of those figures is open to a variety of interpretation, and it would be of interest to ascertain how far they are borne out by the experience of other and larger communities. As far as my own statistics are concerned, one significant fact predominates—viz., that July, which is, or which ought to be, one of the hottest months of the year, has the highest average, whilst June comes within the next column of figures.

One may not unnaturally infer from this that the restlessness and sleeplessness often induced by high temperatures, to say nothing of the bodily exhaustion produced by extreme heat, are not without their influence as factors of the increase in question, and we have only to note the *frequency of mental breakdown in tropical countries* for confirmatory evidence.

I am, Sirs, yours faithfully,

West Malling, Kent, August 24th, 1907. JAMES ADAM.

IMITATION NAUHEIM BATHS.

To the Editors of THE LANCET.

SIRS,—So-called imitations of the Nauheim bath are now so generally employed that it may be worth while pointing out what a difference there is between the cutaneous reaction excited by the effervescing waters of Nauheim and that yielded by water through which carbonic acid gas is merely passed or in which it is generated.

At Nauheim, and to a less extent in baths in which the gas is generated by chemical interaction, the skin becomes covered with minute globules of the gas and on emerging therefrom the subject rivals in hue with the "cardinal of the seas." On this cutaneous reaction depends in part the influence of the Nauheim baths on the circulation, and as it is practically absent when compressed carbonic gas is merely passed through the water of the bath the value of this popular means of aëration must be very small. The difference is well exemplified in the ordinary gazogene. If the water be withdrawn soon after filling, or even within the first few hours after charging, it gives off but little gas and tastes "flat," showing that a certain lapse of time is necessary for the gas to become dissolved. Futher experiment will show that passing carbonic acid through water leaves the latter virtually unchanged. Whatever therapeutical value the Nauheim bath possesses in virtue of its gaseous constituent is due to the latter being in a state of aqueous solution, ready to be set free when the solution comes into contact with the skin.

While it may be conceded that the effects of the Nauheim treatment are only in a minor degree dependent on the action of the gas, this action is lacking when the gas is merely passed through the water. To be operative the gas would require to be left in contact with the water in a cylinder under pressure for at least 12 hours before being employed.

I am, Sirs, yours faithfully,

Aix-les-Bains (Savoie). ALFRED S. GUBB, M.D. Paris.

BUTTERMILK IN ENTERIC DISEASE.

To the Editors of THE LANCET.

SIRS,—The difficulty often experienced by the practitioner in finding any food which can be retained by infants and young children suffering from acute or chronic febrile diarrhœa with vomiting, especially in warm climates, induces me to bring to the notice of your readers a preparation which has a great reputation in the Argentine Republic in cases of this kind and which I cannot find mentioned in any of the books on "Diseases of Children" at my disposal. It might be found useful in the treatment of summer diarrhœa at home. It is sterilised buttermilk, sweetened, and is prepared as follows: Fresh buttermilk is slowly boiled in an earthenware vessel for half an hour—one litre (about 35 fluid ounces) will last for 24 hours—and while gently boiling from five to six dessertspoonfuls of powdered white sugar are added. It must be continually stirred with present the result of my own investigation up to the present time.

HISTORY OF THE STUDY OF POLYMASTIA IN JAPAN.

In November, 1893, I began the first statistical study of polymastia made in Japan, and published the result two years later in the *Mitteilungen der Medicinischen Gesellschaft zu Tokyo.*[1] Previously to that, so far as I know, only two reports had been made in Japan; one was entitled "My Observation on Supernumerary Mammary Glands," by Dr. T. Kuroiwa, Director of the Obama Hospital, Fukuiken,[2] and the other entitled "A Remarkable Case of Supernumerary Mammæ," by Dr. K. Satō of the Kōseikwan Hospital, Nagoya.[3] Both articles, however, being mere reports on a single case, all the valuable statistical reports on the subject have only become available after the above-mentioned publication of mine in March, 1896, and are more or less based upon it. Therefore a mention of the relations between myself and those scholars will constitute by itself a history of the statistical study of polymastia in Japan.

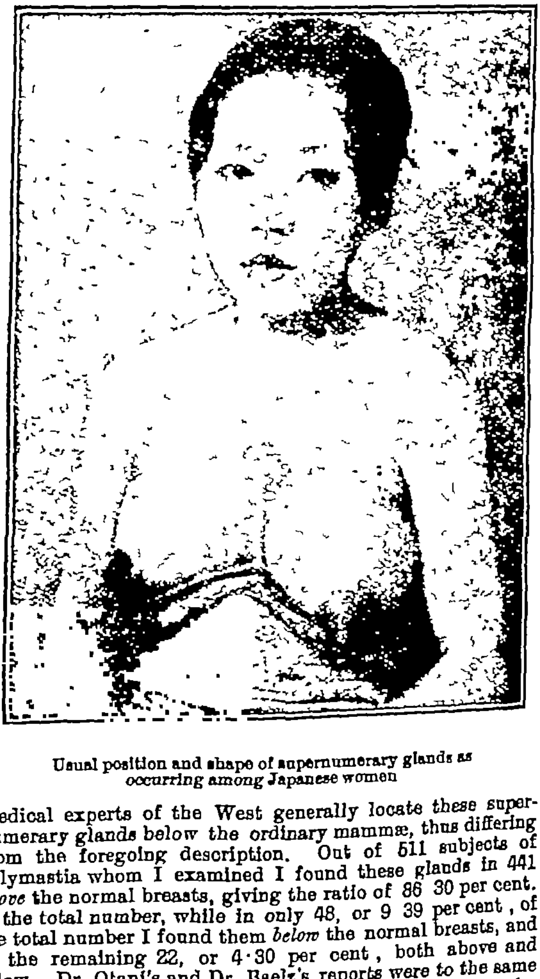
The report of Dr. Kuroiwa just mentioned, together with a figure, is referred to in Dr. R Wiedersheim's "Der Bau des Menschen" (3te Aufl., 1902), but it is to be regretted that he mentions only the name of Dr. K. Horiuchi, who sent him the article, instead of that of the original author, Dr. Kuroiwa. Dr. R. Bonnet also mentions in his work[4] Dr. Horiuchi's name instead of that of the author himself, showing that he was misled by Dr. Wiedersheim's book. The first report I made on the subject fortunately attracted the attention of scientific men in Japan, so that there is hardly a person studying the subject who does not refer to it. The following are some of the extracts from various writers.

In July, 1896, Dr. K. Katayama, professor in the Tokyo Imperial University, in a report on four cases of female polymastia under the treatment of Dr. I. Honda of Kosaka, Akitaken,[5] says that "the readers are advised to refer to the report made by Dr. T. Iwai." In December, 1897, Dr. K. Satō[6] said in his second report: "After I made my first report Dr. Iwai's more minute report appeared, and I began to pay more attention to the subject, and came to the conclusion that polymastia is not rare among Japanese women." In May, 1899, Dr. S. Otani, professor in the Medical School of Nagasaki, assisted by Dr. I. Amemori and Dr. T. Hara, made a minute statistical report[7] At the outset he said: "Since Dr. Iwai has written an article on polymastia it is unnecessary to say anything further." And at the conclusion, following my method of comparison, he gives a statistical table under six headings which coincides with the result I stated in my first report and thus sufficiently proves the correctness of the same. *In April, 1900, when I read* papers at the annual meeting of the Tokyo Medical Association on the Supplementary Report about Polymastia,[8] Dr. H. Uno spoke of the case of a woman at Yokohama, who, after having given birth to a child, was greatly annoyed by having milk dripping from the supernumerary glands she had in both axillæ. Dr. T. Irisawa, professor in the Tokyo Imperial University, made a statistical report on the cases which came under his observation and in general it accorded with my own. Dr. K. Kashida, who made a report, differing from *Dr. Otani's and my own, says that in the* greater number of his cases the glands were found directly under the normal breasts. In the spring of the same year Dr. E. Baelz told me about 48 cases that he had seen; and I found that his observation coincided in general with my own. In May, 1902, Dr. Otani, assisted by Dr. M. Satō, made a supplementary report on polymastia.[9] In its introduction he says: "Among them, we might say that Dr. Iwai's report is most complete and valuable for those who may study this subject." This report of Dr. Otani is on the Relation of Tuberculosis to Polymastia, of which I have the honour to be the first discoverer, and I felt great satisfaction in finding that Dr. Otani's opinion coincided in general with my own; this, however, I discuss more minutely in my essay entitled the "Relation of Polymastia to Tuberculosis," 1907 In October, 1904, Dr. K Satō published a report entitled "An Extraordinary Case of Recurrence of a Supernumerary Gland after its Removal by Operation and the Results of Some Investigations concerning the Subject of Polymastia,"[10] in which he referred to the relationship between polymastia and tuberculosis which I had formerly maintained. He also stated therein that out of 29 cases, subjects of polymastia, he found 19 actually affected by pulmonary tuberculosis or suspected to be tuberculous and began at last to believe that he could safely conclude that "those who are subjects of polymastia are more liable to be affected by tuberculosis."

POSITION OF POLYMASTIA AND STUDY OF ITS PIGMENTATION.

According to my observations the position of supernumerary glands is commonly in our country in the pectoral region, and most commonly they are found in the region II. indicated by Dr. Williams, which is above and external to the normal breasts along the front edge of the axillæ (see Fig 1).

FIG 1.



Usual position and shape of supernumerary glands as occurring among Japanese women

Medical experts of the West generally locate these supernumerary glands below the ordinary mammæ, thus differing from the foregoing description. Out of 511 subjects of polymastia whom I examined I found these glands in 441 *above* the normal breasts, giving the ratio of 86 30 per cent. of the total number, while in only 48, or 9 39 per cent, of the total number I found them *below* the normal breasts, and in the remaining 22, or 4·30 per cent, both above and below. Dr. Otani's and Dr. Baelz's reports were to the same effect—that in the majority of subjects of polymastia the glands were found *above* the normal breasts.

Contrary to the above, Dr. T. Watanabe, captain-surgeon of the Imperial Japanese army, when making an examination of 5452 conscripts in the vicinity of Utsunomiya, compiled statistics of polymastia at my request and found 107 subjects of polymastia, of which 102, or 95·32 per cent, had these glands below the normal breasts, and four persons, or 3 74 per cent., above, and the remaining one, or 0·93 per cent., had them both above and below. Also, according to in Montreal.—At a meeting of the Manchester port sanitary authority held yesterday reference was made to the passing of the "Pure Food" Bill, and pleasure was expressed that Manchester could take credit for having brought about the Bill. Mr. Dearden, the medical officer, said that it would not only bring about the examination of food stuffs at all ports of entry, but would materially assist those authorities who were already holding inspections by clearing up certain doubtful points in the present operative Acts.

Life in a Cellar.

At an inquest held the other day on the three months old son of a Shawforth quarryman a story was told which illustrates the needlessly miserable conditions with which apparently some of our working classes are content. The father earns about 30*s.* a week, but lives in a cellar for which he pays 1*s.* a week rent. There were four children who all slept in one bed with their father and mother. The mother went to bed drunk on the night the baby died. Dr. T. J. L. Forbes of Whitworth, near Rochdale, said that the child had evidently died from smothering by being overlain, which view the jury endorsed by their verdict. They also requested the coroner to call the attention of the Whitworth urban council to "the overcrowded state of some of these cellar dwellings," while the coroner said that "when they are found to be overcrowded and dirty the people should be turned out at once." Surely it is a disgrace to Whitworth that these underground caves, as they may be called, should be allowed to be used as dwellings, although, as all know, the housing of the poor is one of the most difficult problems that municipalities are called upon to solve. But the conditions, however sordid, under which this quarryman lived were to some extent voluntary. His wages were fair and unless his wife was one of that too numerous class, the hopeless and abandoned women drunkards, there seems no reason why they should have sunk to a state so low. Nothing was said as to the father's habits. This case, however, with others of which this is only a sample, shows that whatever social and philanthropical agencies may be at work little can be done to "elevate the masses," as the phrase goes, unless it is their own wish to lead decent lives.

Pigs, Tuberculosis, and Waste Food.

The hospital committee of the Stockport guardians yesterday recommended that all waste food collected from the consumption ward should in future be burned. Mr. J. Worthington said that there were many patients in the hospital in the last stages of consumption who after attempting to masticate their food put it back on their plates. This food was infectious and ought to be destroyed, "but it had been put in the swill-tubs and sold," presumably for pigs. The recommendation of the committee was adopted, and there can be no question that it was the right thing to do. Pigs, as is well known, are very susceptible to tuberculosis. One or two of the guardians, however, seemed to doubt the necessity for burning the refuse food, and one said that he had taken the opinion of medical men on the matter, and "they call it 'piffle.'" The derivation of the well-known term is obscure but its meaning is not, and we are surprised to learn of medical men ridiculing so proper a precaution.

Sept. 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: the Faculty of Medicine.

THE success of the medical school has been well maintained during the year 1906–07. The entry of first-year students has been the highest in the records of the school. The session 1905–06 showed a large increase in the number of new students entering for University degrees—viz., 26 as against the average of 15 for the previous four years. This year the advance in numbers was again most gratifying, the number of new M.B. students entering being 39, an increase of 50 per cent. over 1905–06. In view of the fact that the number of students entering the profession in the country remains practically constant, this increase is a high testimonial to the work of the school and shows its growing reputation as a centre of medical education. As the number of new University students entering is a good index to the condition of the school, the entries for the past six years are here given: 1901–02, 11; 1902–03, 19; 1903–04, 17; 1904–05, 13; 1905–06, 26; and 1906–07, 39. The total number of undergraduate students of medicine (University and diploma) during the past three years is as follows: 1904–05, 121; 1905–06, 129; and 1906–07, 145. An increase is also seen in the number of dental students, the numbers being: 1904–05, 24; 1905–06, 31; and 1906–07, 40. The success of the students in examinations was also maintained at a high level. During the year 1906–1907 three students after passing the Final Examination have been admitted to the Fellowship of the Royal College of Surgeons of England (D. T. Barry, F. A. G. Jeans, and R. E. Harcourt), and Dr. O T. Williams has been admitted to the Membership of the Royal College of Physicians of London. The library has been enriched during the year by the donation of the library of the late Dr. John Cameron, consulting physician to the Royal Southern Hospital, as well as three bookcases containing the volumes. The books in this collection are being arranged and catalogued. The Thompson-Yates library has done good service during the year under the new arrangements provided last year. Mr. R. A. Bickersteth has endowed a scholarship in surgical pathology of the value of £50 for three years, and Mr. W. Thelwall Thomas has renewed the Thelwall Thomas scholarship in surgical pathology for a further period of three years. During the year the honour of knighthood has been conferred on Professor Rubert W. Boyce for his services in tropical medicine in connexion with the Liverpool School of Tropical Medicine. Academic distinctions have been conferred upon several members of the staff by other universities. The University of Aberdeen has conferred the honorary degree of LL.D. upon Professor J. Campbell Brown and Professor Ronald Ross, C.B. The University of Harvard has accorded a similar honour to Professor C. S. Sherrington. Professor T. R. Glynn has been elected a member of the Council of the Royal College of Physicians of London, and Professor Sherrington has been elected a foreign member of the Royal Academy of Sciences at Göttingen. The latter has also been appointed to the newly formed lectureship in neuro-biology. Professor F. T. Paul having resigned the professorship of toxicology and forensic medicine has been given the title of emeritus professor. The chair has reverted into a lectureship and Dr. R. J. M. Buchanan was appointed lecturer of that department. A lectureship in physical anthropology has been established and Dr. W. H. Broad has been appointed to the post. The title of clinical lecturer in the University has been conferred upon the physicians and surgeons of the four general hospitals of the clinical school of the University and upon the physicians and surgeons in charge of out-patients at the Liverpool Royal Infirmary. Mr. A. W. Mayo Robson has accepted the invitation of the council to deliver the third William Mitchell Banks memorial lecture on Nov. 27th.

The Death rate of St. Helens.

The death-rate of St. Helens during the past fortnight has fallen from 17·7 per 1000 to 13·2 per 1000, as against a corresponding rate last year of 19·3 per 1000. There has also been a remarkable decline in infantile mortality, only 17 deaths having occurred of children under one year of age. Under five years of age there have been 24 deaths, against 39 last year. There has been an entire absence of deaths from the more serious zymotic diseases. The birth-rate was 33·7 per 1000. The Liverpool death-rate for the same period was 14·8 per 1000, whilst the birth-rate was 32·2 per 1000

Sept. 3rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Isolation of Consumptives at Newport.

THE borough of Newport (Mon.) is well provided with hospital accommodation for the isolation of infectious diseases. Within quite recent years an institution on the pavilion plan has been established in an elevated position in the town and it has done admirable work. During last year the medical officer of health (Dr. J. Howard-Jones) suggested that one pavilion should be devoted to the treatment of consumptive patients. This suggestion

Thus, we find the number of supernumerary glands above the normal breasts is greater by far than those found below, the former being 90·03 per cent. while the latter is only 9·96 per cent. As to the position of right or left, there is no doubt that the greater number occurs on the left rather than on the right, showing the ratio of 52·76 per cent. to 47·23 per cent. respectively.

In regard to the pigmentation of areola, I believe that in the great number of cases of polymastia in males the pigmentation is more marked than in females; and again, regardless of the sex, those situated below the normal breasts show more pigmentation than do those above. Dr. Irisawa, confirming my observation, states that such glands found below the normal breasts show more pigmentation than do those above. In regard to the pigmentation in cases of polymastia I have carefully analysed 399 and obtained the following result :—

TABLE I.

Total number of supernumerary glands 399.	Male	132	Pigmented ...	63	47·72%
			Normal... ...	49	37·12%
			Unpigmented	20	15 15%
	Female	267	Pigmented ...	64	23·97%
			Normal... ...	167	62 54%
			Unpigmented	36	13·48%

TABLE II.

Total number of supernumerary glands 399.	Above normal breasts ...	345	Pigmented ...	79	22·89%
			Normal... ...	216	62 60%
			Unpigmented	50	14 49%
	Below normal breasts ...	54	Pigmented ...	48	88 88%
			Unpigmented	6	11·11%

Dr. Otani and others hold that there is very little connexion, if any, between pigmentation and pregnancy and say in proof thereof that there was a woman who gave birth five times yet had no pigmentation in the areola; and again, they say that among the males there are comparatively more with pigmentation than among the females. Nevertheless, there can be no doubt, according to my own observation, that during pregnancy the areola of supernumerary mammary glands becomes darker in colour.

RATIO OF POLYMASTIA IN JAPAN AND ITS RELATION TO SEX.

The ratio of cases of polymastia found in Japan varies not only according to the investigators but even the same authors do not, or cannot, always give the same rate. As shown in the accompanying table, Dr. Otani gives in his first report a higher rate of cases than does my own first report, and again his second report shows a rise of ratio over the first. My own reports, made at several different times, show a gradual rise in ratio every time. This is due, I trust, to the better method applied in the investigation and the skill attained through more extended practice. The total number of persons (female sick nurses, students, patients, and so on) examined by me at several different times was 11,789. Out of this number 443 were subjects of polymastia, or a ratio of 3·75 per cent. of the total number. Dividing the total number between the sexes I found out of 6803 males 139 (or 2·04 per cent.) were subjects of polymastia, and out of 4986 females I found 304 (or 6·09 per cent.) were subjects of polymastia. Adding to these 17 males and 65 females recorded in my note-book gathered from various sources we have in all 156 males and 369 females, or a ratio of 2·36 females for 1 male. The total number of subjects examined by three physicians at different times (twice by Dr. Otani, once by Dr. Watanabe, and others by myself) amounts to 32,922, out of which 917 (or 2·44 per cent.) were subjects of polymastia. When we divide this number between the sexes, out of 22,577 males there were 380 (or 1·68 per cent.), while out of 10,345 females there were 537 (or 5·19 per cent.), showing that the ratio of polymastia in females is three times larger than that in males.

I believe that we can safely take the above figures, obtained through various investigations by different persons, as the fixed standard ratio of cases of polymastia in Japan. Dr. Leichtenstern states that polymastia is found at the rate of 1 in 500 persons; and, further, he declares that the number is equally frequent among males and females, but out of 13 cases which he cited nine were males and four were females. Dr. Bonnet obtained 92 cases from various authorities and divided them as follows: 22 males and 70 females. Out of 262 cases gathered by Dr. Hansemann, 81 were males and 104 were females. Nothing is said of the remaining 77 cases in regard to sex. Dr. J. Mitchell Bruce, who was the first to take note of polymastia in males, found out of 3956 persons examined by him in three years 61 cases, or a ratio of 1·54 per cent. Dr. Bardeleben in his first report gives the rate of males as 9·1 per cent. and that of females 4 8 per cent.; but in his later report, made after he examined the conscripts, he raised the ratio of males to over 14 per cent. Dr. Ammon found 114 subjects of polymastia out of 2189 conscripts examined in Baden, Germany, which makes a ratio of 5·2 per cent. Out of the 114 subjects, 66 persons (3·01 per cent.) had distinct supernumerary mammary glands, while the remaining 48 persons (2·19 per cent.) had considerably less distinct ones. Dr. Watanabe found, as stated before, 107 subjects (1·96 per cent.) out of 5452 conscripts examined in the vicinity of Utsunomiya.

Recently I met with a wonderfully high ratio of polymastia when I examined 159 nurses. Out of that number I found 43 subjects (27·04 per cent.) of polymastia. Among them 16 persons (or 10·06 per cent.) had very distinct ones, while the remaining 27 (or 16·98 per cent.) had less distinct ones. Again, out of 100 candidates (males only) for entrance to the school of the Formosan Association, there were 17 subjects of polymastia, making a ratio of 17 per cent.

NUMBER OF GLANDS IN CASES OF POLYMASTIA.

As I have stated before, it is common in Japan to find only one supernumerary gland on both right and left sides. I have found, in my observations, only 32 cases having more than 3 out of 511 subjects of polymastia—namely, 1 woman having 6 in number; 2 women having 5; 5 women and 6 men having 4; and 9 women and 8 men having 3. As far as I know, the case cited by Dr. Neugebauer, in which the woman had 6 above the normal breasts and 2 below, is the most remarkable one hitherto known. Dr. Hennig, adding 11 cases which he had observed himself to 105 cases of Dr. Leichtenstern, classified as follows: 51 cases having 3 in number; 33 cases having 4; 2 cases having 5; and 2 cases having 6. Nothing is said of the number of glands found on the remaining 28 subjects. Dr. Puech classified 77 cases as follows: 46 cases having 3 in number; 29 cases having 4; and 2 cases having 5. Dr. Ammon classified 66 cases as follows: 62 cases having 1 in number; and 4 cases having 2. Dr. Watanabe classified 107 cases as follows: 1 case having 3 in number; 25 cases having 2; and 81 cases having 1. Judging from the above it seems that those who have the larger number of such supernumerary glands are females.

HEREDITARY TRANSMISSION OF POLYMASTIA AND ITS BLOOD-RELATION.

Several experts have written on the hereditary nature of polymastia. Dr. Leichtenstern states that in one-thirteenth of the total number of cases observed there was an indication of its being inherited. The case cited by Dr. Péterquin is a remarkable one, three sons and two daughters having inherited polymastia from their father. In 1892 Dr. Bonnet wrote that there were five cases of hereditary transmission known up to that time, of which three cases were transmitted from mothers to daughters. Dr. Neugebauer, citing Dr. Martin's cases in which the transmission continued for three generations, says that he observed many instances in which such anomalies were not inherited.

Out of 555 cases which came under my observation I found 31 cases (or 6 per cent.) of hereditary transmission and five cases (or 0·97 per cent.) where brothers and sisters had them alike.

1 case from mother to 2 sons, 2 daughters, and 1 granddaughter.
1 „ „ „ 2 sons and 3 daughters.
2 „ „ „ 1 daughter and 2 granddaughters.
1 „ „ „ 2 daughters and 1 grandson.
1 „ „ „ 1 son and 2 daughters.
3 „ „ „ 1 daughter.*
2 „ „ „ 2 daughters.
8 „ „ „ 1 son.
10 „ „ „ 1 daughter.
1 „ „ „ 1 daughter and 1 granddaughter.
1 „ „ father to 1 daughter.
1 „ in which elder and younger brothers had them alike.
4 „ in which elder and younger sisters had them alike.

* The mother's younger brother was also a subject of polymastia.

As may be observed from the above, hereditary transmission is generally from mothers and I have met with only one plan consisting of four elements: (1) Segregation in hospitals of advanced cases; (2) sanatoriums for incipient cases; (3) tuberculosis dispensaries in large centres of population; and (4) local committees appointed by sanitary authorities to deal with the question of consumption. But in addition the Irish Local Government Board wisely follows the memorandum of the Scotch Board and recommends compulsory notification of pulmonary tuberculosis carried out by special legislation, safeguards being provided to insure that no unnecessary restraint is placed upon the liberty of consumptive patients. Special reference is made to what is being done by the Belfast guardians at their Abbey Sanatorium, where £34,000 in all will be spent (when the place is completed) on the site and the erection of the buildings and where there will be accommodation for 265 consumptive patients. Finally, the report refers to the Tuberculosis Exhibition, of which details are given below.

Women's National Health Association of Ireland: Tuberculosis Exhibition.

A meeting of the consultative committee of the Women's National Health Association of Ireland, composed of delegates from medical societies, county councils, and urban and district rural councils throughout Ireland, was held at Leinster House, Dublin, on August 29th, to confer as to the best methods for making the forthcoming Tuberculosis Exhibition as effective as possible. This exhibition, the first of its kind established in the United Kingdom, is to be held at the Home Industries Section of the International Exhibition during the month of October. The Countess of Aberdeen presided and said that when the Women's National Health Association of Ireland, which was formed in March of this year, began to consider the subjects with which it would have to deal, naturally the first was that disease which caused such terrible ravages in Ireland—tuberculosis—and in collecting literature on the subject their attention was directed to a plan which had been adopted in Germany and the United States of America of forming an itinerant exhibition which would show the need of an educational campaign against this dread disease. After being opened at the great exhibition in Dublin, the Tuberculosis Exhibition would be sent to the poorer parts of Dublin and then to the other cities and rural districts of Ireland. Those having charge of the various sections of the Tuberculosis Exhibition then gave short descriptions of the details of those sections, the Deputy Registrar-General presenting diagrams and statistics showing the extent in Ireland and gradual increase of tuberculosis. Professor E. J. McWeeney described the pathological and bacteriological section, Dr. Lily A. Baker the cooking section, dietary, and milk sterilisation; Dr. Alfred E. Boyd dealt with the literature (including illustrations from other countries) section; Dr. W. J. Thompson described the section which would have appliances and various exhibits bearing on treatment; and Dr. M. F. Cox spoke of the section for arrangement for lectures and demonstrating. Professor Mettam of the Irish Veterinary College is to have charge of the important section bearing on tuberculosis in veterinary medicine. The following motion—

> That we, the members of the consultative committee, having had placed before us a statement of the steps taken by the executive committee with the object of forming a representative and instructive collection of objects illustrating in a popular manner the subject of tuberculosis and its prevention, do hereby approve the same, and we hereby pledge ourselves to do all in our power to make this exhibition a success—

was proposed by Sir H. R. Swanzy, President of the Royal College of Surgeons in Ireland, who said the exhibition was a big undertaking, but he hoped that everything possible would be done to make it a success. Lord Frederick Fitzgerald seconded the motion, which, having been supported by Mr. J. Lentaigne (Vice-President of the Royal College of Surgeons in Ireland), Mr. D. Jamison (medical officer of health of Newtownards), and many others, was unanimously carried. Dr. W. Calwell (delegate from the Ulster Medical Society) in proposing the next motion—

> That we consider it of urgent importance to the welfare of the nation to elicit opinion and diffuse information as to the best means of dealing with an overwhelming evil which is destroying the vitality of our people; and that this meeting desires to draw attention of local public bodies and of philanthropic organisations in Ireland to the educative value of the forthcoming exhibition, and recommends that steps should be taken to bring visitors to inspect it, and that arrangements should be made to take it to different parts of the country—

said that while there was an overwhelming evil to be combated they found in this exhibition a means of doing so. If Ireland had the same mortality from tuberculosis as was found in England and Scotland some 3000 or 4000 people would be alive at the end of the year 1907 who, with the existing mortality in Ireland, would then be dead. He said they would make an effort in Belfast to support such an admirable scheme. Mr. P. J. O'Neill, J.P., chairman of the Dublin county council, having seconded the motion, Sir John Byers very warmly supported it. He showed that while, since about the year 1870 to the present time, both in England and Scotland the mortality from tuberculosis had fallen one-half in women and one-third in men no such decrease had taken place in Ireland, where the deaths from the disease had actually increased. What they wanted to do was to educate the people as to this terrible mortality and to show them that tuberculosis could be prevented, and that there were great hopes of treating it in the early stages. How better could such facts be brought before the people than by the objective teaching and demonstrations given in such an exhibition? Speaking for the profession in Belfast, they would do everything in their power to make this Tuberculosis Exhibition a success when it visited their city. The motion having been carried, a very hearty vote of thanks was passed to Lady Aberdeen for presiding. No delegates from the Belfast public health committee were present.

Health of Belfast.

It is satisfactory to find that the death-rate of Belfast for the four weeks ended August 17th has fallen to 15·4 as compared with 18·3 in the previous month and 17·8 in the corresponding period of last year. It is the lowest death-rate ever registered in Belfast. There is a marked reduction in the infectious diseases.

Sept 3rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

An Action for Damages on account of Alleged Burning by Electricity.

AT the Congress of the French Association for the Advancement of Science held at Reims in August M. Laquerrière gave some account of a singular case. A man had received some injury in the course of his employment and the diagnostic methods which were resorted to included the application of electricity. He thereupon charged the medical man with causing him personal injury by negligence, and when it was evident that he had not sustained any harm he changed his tactics and claimed compensation on the ground that he had been for two months incapacitated for work by the procedures. A medical expert who was consulted found some slight cicatrices at the site of the alleged injury but was of opinion that there had been no scorching (*brûlure thermique*) of the tissues as the patient had felt nothing unusual immediately after the examination. There was no distinct evidence that an "electrical burn" (*brûlure électrique*) had occurred, and in the result the charge brought against the medical man was dismissed.

The Responsibility of a Nursing Association for a Dishonest Nurse.

In response to a patient's request for a male nurse the Société des Ambulances Parisiennes sent a man who appropriated money to the amount of 2250 francs (£90) and was sentenced to three years' imprisonment for the offence. The patient, holding that the Société des Ambulances Parisiennes was responsible for the acts of a nurse in its employment, then brought an action against it for the recovery of the money and judgment was given in his favour.

Scarlet Fever in Paris.

I have already mentioned the epidemic of scarlet fever which commenced last spring and continued through the summer. During the week ended July 20th there were 583 cases notified, but during the ensuing three weeks there was a marked decline, so that during the week ended August 10th there were only 255 cases notified. There is therefore a prospect of the disease subsiding to its usual level of about 50 cases per week.

Sept. 3rd.

4. Six is the largest number of glands yet found on one person.

5. It is certain that polymastia is inherited and in most cases is transmitted from mothers.

6. In the perfect supernumerary mammary glands secretory process begins at the time of parturition and sometimes it continues for over six months.

see him. Shortly before his death he, at the instance of his family, allowed a medical man to be called in who diagnosed nervous exhaustion, cause unknown, and the death which occurred a few days after was attributed to this condition. A conversation overheard at the funeral led the police to make inquiries, with the result that a band of criminals, headed by an Italian fencing-master whose name had been mentioned at the funeral, were found to have been in intimate friendship with the deceased. The fencing-master's rooms were found to be a place in which spiritualistic meetings were held and a prominent member of these meetings was the lawyer in question. He made the acquaintance of the fencing-master some six years ago, just at the time when his nervous symptoms began to be obvious. It was found that he had become an actual slave of the "angel who duly appeared at every *séance*," and who, as has been ascertained, was the product of ventriloquism. This angel summoned the lawyer to the *séances* from day to day and by his utterances made him spend money and refuse to see any medical attendants. His family's remonstrances were futile and they could not dissuade him from frequenting the *séances*. The Budapest police authorities are now in possession of information concerning everyone connected with the *séances*, and the fencing-master and his companions will be prosecuted. The medical faculty is very much moved by the affair and its members intend to make a proposal to the legislature as to the compulsory closing of all such spiritualistic meeting-houses.

French Medical Men in Marienbad.

On August 16th 26 French medical men, all members of L'Œuvre d'Enseignement Médical Complementaire, with Dr. Etienne Barot at their head, came to Budapest to see its medical institutions. Before coming to Budapest they stayed in Marienbad where they heard the lecture of a Hungarian medical man. The Marienbad Medical Society intrusted the delivery of the gala address to Dr. Ödön Tuszkai who carried out the task excellently. The guests received his lecture (delivered in French), dealing with the therapeutical value of Marienbad, upon physical and chemical grounds, with great approbation and applause. Professor Monprofit (of Angers) warmly thanked the lecturer. Dr. Tuszkai, after the lecture, conducted the guests to the springs and at dinner he, in a very amusing speech, proposed the health of the French ladies who were present in great numbers.

August 30th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Vital Statistics

THE Commonwealth Bureau of Census and Statistics has issued a summary of vital statistics for the years 1901 to 1906. In 1906 the total number of births for the Commonwealth was 107,890, the largest during the period under review. The average birth-rate for 1906 was 26·41. Queensland heads the list of illegitimate births with 7·68 as against 7·04 in New South Wales; then follow Victoria, Tasmania, and South Australia. The statistician remarks that but for the low death-rate the low birth-rate would be a serious national danger for Australia. The death-rate per 1000 in 1906 was 10·9. The rate of natural increase in Australia as compared with other countries in 1905 06 places it above any of them except Holland, with which it is practically identical.

Federal Quarantine.

The Commonwealth Government has introduced a Bill to enable the quarantine administration to be placed under federal control. The Bill is practically a consolidation of the various State quarantine regulations. It is to be administered by the Minister of Trade and Customs. It proposes to enable the executive to declare by proclamation "any ports in Australia to be the first port of entry for oversea vessels" and to prohibit "the introduction into Australia of any noxious insect or any pest, or any disease germ, or microbe, or any disease agent, or any culture, virus, or substance containing any disease germ, microbe, or disease agent." Animals or plants believed to contain disease germs may be excluded, and any part of the Commonwealth in any State where any quarantinable disease exists may be declared a quarantine area. Heavy penalties are provided for masters of vessels entering ports with unreported cases of disease on board their ships.

Leprosy in Australia.

The annual report of the Board of Health of New South Wales on leprosy shows that on Jan. 1st, 1906, 18 persons remained at the Little Bay lazaret. During the year nine persons were reported to the board as suspected lepers, and of these six were ultimately admitted as genuine cases. One other case reported previously but not legally certified brought the total number of admissions for the year up to seven. One patient died and four were discharged, leaving 20 remaining in the lazaret on Dec. 31st, 1906. Tasmania reported one case, the patient being a Chinese immigrant. Victoria and West Australia recorded no case and South Australia furnished no return. Queensland reported 14 cases, of which only three were whites, one being an Australian-born youth, aged 16 years, suffering from the nodular type of disease.

Lunacy Reform in Victoria.

On July 3rd the Melbourne morning papers published a long letter from Dr. J. W. Springthorpe, one of the official visitors to the Kew and Jarra Bend Asylums for the Insane. This letter was dated June 30th and had been sent to the members of the Victorian Cabinet. Its substance may be gathered from its opening sentence:—

> GENTLEMEN,—I find it my unpleasant duty to report that, despite the extended powers of the amended Lunacy Act, and despite also the generous and sympathetic support of the Government, there are still in our metropolitan asylums practically the same overcrowding, the same deficiency in the number and training of attendants, the same lack of trained nurses, and the same want of proper care and treatment of the acutely sick and the acutely insane that characterised them prior to the recent crusade for lunacy reform.

Dr. Springthorpe thereafter gave specific instances of what he considered undesirable in the existing state of affairs. On the same day Mr. Ernest Jones, Inspector-General of Asylums for the Insane in Victoria, wrote a lengthy rejoinder traversing Dr. Springthorpe's charges. This document was prepared at the request of Sir Alexander Peacock, the Chief Secretary of the Victorian Government, who also expressed surprise that Dr. Springthorpe had supplied his letter to the daily press. Other observers, without making any direct reference to Dr. Springthorpe's views, have practically confirmed most of his criticisms. That the Kew and Jarra Bend asylums are obsolete and grossly overcrowded has been pointed out repeatedly for many years. It was hoped that when the new Lunacy Act came into force some four years ago reforms would speedily be brought about. So far this does not appear to have resulted, but the general opinion is that the delay is caused by the cumbrous political control which renders the position of inspector-general an anomalous one in many directions and seriously curtails his power of prompt action. Further communications to the daily press by Dr. Springthorpe have been made in which he reiterates his views, and Sir Alexander Peacock has announced his intention of making a personal inspection of the asylums.

Obituary.

Mr. A. S. Gray, M.R.C.S. Eng., one of the leading figures of the profession in Melbourne for many years, died on July 10th, at the age of 81 years. The late Mr. Gray was born in Dublin and came to Victoria in 1856. He soon established himself in Melbourne as an oculist and aurist and built up a very large practice. In 1863 he founded the Victorian Eye and Ear Hospital and maintained it for some years at his own expense. In 1867 its scope was so large that it was placed under the management of a committee and professional staff, the founder remaining connected with the institution up to the time of his death. He was president of the Medical Society of Victoria in 1880 and filled many honorary positions as surgeon to public bodies. He held the rank of lieutenant-colonel in the Militia service and was a keen sportsman in his younger days.

Infant Life Protection.

Dr. Norris, chairman of the Board of Public Health in Victoria, has recently drawn attention to the mortality among illegitimate and boarded-out infants, remarking that Victoria is the only community in the world where the supervision of boarded-out infants is left entirely in the hands of the police. Dr. Norris has further submitted a number of "suggestions" which have been adopted by the below, and the sac was removed; a troublesome kind of operation in comparison with the simplicity of that for extirpating a spontaneous aneurysm, and if excision is a successful treatment for diffuse aneurysm, the same plan can be used with greater confidence to the spontaneous form, because in the latter a better chance has been afforded for the establishment of the collateral circulation. As examples of the failure of ligature to cure a popliteal aneurysm a case recorded by the late Christopher Heath may be quoted.[4] 14 days after ligature of the femoral the pulsation in the sac was again as forcible as before operation; the aneurysm was excised by Victor Horsley. A second case of popliteal aneurysm was treated by ligature of the femoral by Mr. Heath, but four weeks later Mr. Horsley amputated the thigh for gangrene. Littlewood[5] recorded a case of popliteal aneurysm treated by excision of the sac, and urged this method of treatment of diffuse aneurysms of the arteries of the limbs; he also opined that the same method would meet with favour as the best for treating aneurysms in the same situation before they became diffuse. Before the Leeds and West Riding Medico-Chirurgical Society on March 16th, 1897, the same surgeon showed a man from whom he had excised a diffuse popliteal aneurysm.

In five of the cases in the table referred to no previous treatment had been tried, and in some of the others no statement appears on this point. In my case no attempt at treatment was made other than by extirpation; no doubt extirpation can always be fallen back upon as a last resort after the failure of compression or ligature, but it seems to me, in the light of modern surgical opinions, that extirpation should be a first resort rather than the last. Perhaps in the same way that the uncertainty of the truss has led up to the greater security afforded by methods of radical cure for hernias, it may be found that compression, flexion, and tying the femoral will give way to the more satisfactory way of curing an aneurysm, wherever possible, by extirpation. In this respect we shall again be the debtors of Lord Lister, for radical cures of hernia are done as routine operations owing to the safety of aseptic means, and extirpation of an aneurysm loses a very large part of its risk owing to the same means.

Until a sufficient number of cases is collected it will not be possible to make a comparison between the value of extirpation as contrasted with ligature, but the cases recorded from foreign sources are accumulating and before long it will be possible to say more definitely than at present. Tillmans[6] says that the results of ligature of the femoral artery are uncertain and that the surest treatment for popliteal aneurysm is extirpation of the sac. The prognosis of excision of the sac Tillmans considers more favourable in idiopathic and old traumatic aneurysms than in fresh traumatic aneurysms, because in the latter the re-establishment of a sufficient collateral circulation is impeded in consequence of the pressure of the surrounding tissue which is infiltrated with blood.

Without unduly advocating the more modern method of excision of an aneurysm, it may be well to point out that even successful treatment of an aneurysm may not prove to be a permanently successful cure. Some years ago I was consulted about a case of gangrene of the foot and leg in a man between 70 and 80 years of age. I amputated at the knee level and turned out a solid fusiform aneurysm of the popliteal artery at its upper portion. This aneurysm had not been recognised before operation and the gangrene was supposed to be of senile origin. The aneurysm was filled with solid, firm clot and probably contributed to, if it did not actually cause, gangrene. The operation of Antyllus will hardly be introduced again, but the success attending it will lead to a bolder method of dealing with aneurysms in all accessible parts of the body. Antyllus ligatured the vessel above and below the sac, then opened it, and turned out the clots, but did not extirpate. According to Tillmans[7] "the literature of the subject gives, according to Köhler, 14 cases of extirpation of popliteal aneurysms by the method of Antyllus which resulted favourably."

In what cases should extirpation be attempted or done cannot be definitely stated at present, but seeing that the methods employed hitherto are uncertain I think there is good reason for taking immediate recourse to extirpation in all aneurysms in accessible positions, whether subclavian, femoral, carotid, or popliteal, for the results obtained, scanty in number though they may be, are sufficiently encouraging to warrant any surgeon giving the newer method a favourable consideration. Writing in 1895 the article on Aneurysm in "A System of Surgery," edited by Treves, A. Pearce Gould says[8]: "Several cases of excision of aneurysm have recently been recorded and it is probable that this mode of treatment will be employed more frequently in the future than in the century following Hunter's memorable operation."

"Excision," says Bilton Pollard,[9] "is, in my opinion, the best treatment for all aneurysms situated in accessible positions and no aneurysms are more suited to that method of treatment than femoral aneurysm." The popliteal region is one eminently adapted for extirpating an aneurysm, but in other regions less accessible aneurysms have been dealt with in the same manner—for instance, to the late H. W. Allingham[10] we owe a brilliant example set by his successful excision of a subclavian aneurysm in circumstances of far-greater difficulty than could ever be encountered in the popliteal region. In 1900 I operated upon a subclavian aneurysm after Allingham's plan, meeting little or no difficulty.[11] The patient returned to his occupation in the same workshop as a fitter, doing the same work and getting the same wage as before, being absolutely cured, and is still at work as a mason's labourer. This result more than anything else induced me to attempt extirpation of the popliteal aneurysm now recorded.

Carlisle.

ACTINOMYCOSIS OF THE APPENDIX.

BY A. RENDLE SHORT, M.D., B.S., B.SC. LOND.,
SENIOR RESIDENT OFFICER TO THE ROYAL INFIRMARY, BRISTOL.

ACTINOMYCOSIS of the vermiform appendix was first observed by Barth who described two cases in 1890; the first case recognised in England was recorded by Ransom in 1892. Since attention has been directed to the location of actinomycosis in the right iliac fossa it has become evident that a number of the cases really originate in the cæcum, and an identical clinical picture may result after perforation. Hence a preferable title would be "actinomycotic perityphlitis" and such will be the scope of the present thesis, though the more usual designation has been preserved above. Three cases have come under my charge in the past year and I describe two more from the annals of the Bristol Royal Infirmary. The notes of the cases are as follows:—

CASE 1.—The patient was a male, aged 14 years. He was admitted on Sept. 28th, 1900, complaining of a painful lump in the abdomen. There was nothing of importance in his previous history. 21 days ago he suffered from pain in the appendix region, two days after a school feast. There was no vomiting. The bowels were costive. The pain had been getting steadily worse and a week ago a lump was noticed. There was no history of swallowing any foreign body. On admission the boy was found to be pale, thin, and looking ill, with much pain. The temperature was 100° F., the pulse was 116, and the respirations were 20. The chest was normal. There was a large, hard, prominent lump occupying the whole of the right iliac fossa from the umbilicus to Poupart's ligament, extending somewhat beyond the middle line. It fluctuated a little and was adherent to the abdominal wall, but the skin was not discoloured. It could be felt per rectum. On the next day an incision was made under chloroform and pus was evacuated from the parietes under the skin; there was a hole through the muscles and a large deep cavity about the cæcum containing much dark fœtid pus. From this a bent pin was extracted. The cavity was surrounded by massive adhesions and the appendix was not found. A tube was inserted. The boy's condition did not improve; he still had a hectic temperature, and fresh collections of pus pointed, and were opened, below the umbilicus and above the pubes, on Oct. 4th, 21st, and 30th. From each foul pus was let out. The cavities, which all communicated, were thrown investigation: (5) making drawings of skin patients; and (6) the study of skin disease by means of a laboratory or otherwise. In the case of each charity the trustees may, with the consent of the Charity Commissioners, apply for any one or more of the purposes indicated above by an asterisk (*) any part not exceeding one-third of the capital endowment of the charity and any investments which may from time to time represent unexpended income.

[11] Transactions of the Clinical Society, vol. xxxiii., p. 246.

Donations and Bequests.—Under the will of Mr. William Marsh, West Bromwich, Staffordshire, the West Bromwich District Hospital will receive £1000, the Royal National Lifeboat Institution £500, the Staffordshire Congregational Union £400, the High-street Congregational Church, West Bromwich, £400, the London Missionary Society £350, the Birmingham General Hospital, £350, and a similar amount to the Queen's Hospital, Birmingham.—Lady Wantage has contributed £100 and the Hon. W. F. D. Smith, M.P., has contributed £25 towards the special fund in aid of the Royal Buckinghamshire Hospital, which now amounts to £3842.

New Sydenham Society.—The forty-eighth general meeting of this society was held in Exeter on August 1st, Professor W. Osler being in the chair. The minutes of the last meeting were read and confirmed. The report and balance sheet for 1906 were presented. The report concluded with a recommendation from the council that the society should not be continued beyond the end of the current year. In response to a request from the chairman, Mr. Jonathan Hutchinson said that though he had himself written the report adopted by the council he was not wholly in accord with the recommendation that the society should wind up its affairs. There were still nearly 900 members and his sympathies went with the proposal that the society should continue its work with certain modifications. He would propose to publish every year a volume of clinical lectures, short monographs or papers, translated from foreign sources as promptly as possible after their original issue. The work of abstract making which the society's year-book used to accomplish was now exceedingly well done in the medical journals, but not a few of the papers with which medical literature now teems were well worthy of reproduction in full, and a valuable and attractive annual volume might be thus constructed. Secondly, he would like to see the Atlas continued but with plates reduced in size and with less letterpress. It should copy nothing and produce only original illustrations of new subjects. It might suitably treat the subjects comprised in the volume of translated monographs. It might also undertake to reproduce selected drawings from among those exhibited at the annual meeting of the British Medical Association, and for this it might venture to ask for a subsidy. It might also come to an arrangement with the Royal Society of Medicine to publish some of the plates accompanying papers read before the society, thus giving them a wider circulation and at the same time enriching the Atlas. It might be worth a thought whether a remodelled society might not become more international in character and enter into close relations with all English-speaking communities. He much hoped that the society would not be given up but that it should be remodelled somewhat on the above lines. Dr. J. T. Leon proposed that a circular should be sent round to the members in which they should be asked whether they were in favour of the recommendation made by the council that the society should not be continued beyond the end of the current year, or of carrying on the society on the lines suggested by Mr. Hutchinson. This was seconded by Fleet-Surgeon P. W. Bassett-Smith and carried unanimously. Dr. F. J. Baildon then urged that in view of the importance of this step it would be well that a statement of the outstanding liabilities and of all the assets of the society should accompany the circular. This was seconded by Dr. C. Gibson and carried. Dr. R. H. Coombs proposed that the statement should be made by a chartered accountant. This was seconded by Dr. Gibson and carried. Mr. H. Power pointed out that many subscribers were more than satisfied with the Atlas, and that some had paid for several years in advance. Dr. A. E. Russell drew attention to the fact that the income of the society had steadily diminished for several years past. There was unfortunately no indication of any recovery as a large number of resignations had been received this year. At the present moment the society was solvent, and if no further diminution in its members occurred it could just be carried on, but with any further shrinkage a deficit would have to be faced or its output would have to be diminished. The meeting terminated with the usual votes of thanks.

Hospital Saturday at Penzance.—August 17th was observed in Penzance as Hospital Saturday, when a sum of £98 was collected.

Bristol Medical Charities.—As the result of the Licensed 'Victuallers' fourth annual charity carnival, recently held in Bristol, the sum of £174 has been handed to the funds of the Bristol medical charities.

St. Mary's Hospital Medical School.—The winter session will commence on Wednesday, Oct. 2nd, when the prizes and awards for the past year will be distributed, and an introductory address delivered by Professor Osler, M.D., LL D., F R.S., Regius Professor of Medicine in the University of Oxford. The annual dinner of past and present students will be held at 7 P.M. the same evening in the Whitehall Rooms, Hôtel Métropole.

Notification of Glanders, Anthrax, and Hydrophobia.—The Local Government Board for Scotland has issued circulars to all medical officers of health, signed by the Secretary, stating that the Board has been approached by the Board of Agriculture and Fisheries as to the desirability of making arrangements for the notification of cases of glanders, anthrax, and hydrophobia in man, where the facts pointed to the possibility of infection to the human subject from an animal or its carcass, or where inquiry under the Diseases of Animals Act seems to the medical men concerned to be *primâ facie* desirable. The circular goes on to state that the Board is satisfied as to the advantage of such an arrangement with a view to checking the spread of these diseases. The medical officer of health is requested to communicate to the clerk to the local authority under the Diseases of Animals Act such cases or suspected cases of glanders, anthrax, and hydrophobia in man as may come to his knowledge. A similar circular has been sent to the clerks to the local authority stating that medical officers of health have been instructed as above mentioned.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Butter and Margarine Act.

AMONGST the Bills which received the Royal Assent on Wednesday, August 21st, was the Butter and Margarine Act, 1907.

The Conclusion of the Session.

The Parliamentary session concluded on Wednesday, August 28th, when the Royal Assent was given to a number of Bills which have been agreed upon by both Houses of Parliament. Several of those measures are of interest to the medical profession. Amongst the Bills which have become law are the Public Health (Regulations as to Food) Act, the Education (Administrative Provisions) Act, with its clause instituting the medical inspection of school children, the Public Health Act, the Vaccination Act, the Vaccination (Scotland) Act, the Public Health (Scotland) Amendment Act, and the Notification of Births Act. Other measures which were interesting to the medical profession have been placed before Parliament by private members this session. Few of them, however, made sufficient progress to receive the Royal assent. A Bill to prohibit medical practice by companies, which was brought forward by Lord HYLTON in the House of Lords, was made the subject of a special inquiry by a Select Committee. It was strongly supported by Dr. DONALD MACALISTER and Mr. C. S. TOMES on behalf of the General Medical Council and its passage through the Upper Chamber was easy. However, the Government did not adopt it and afford it facilities, and unfortunately it did not get a second reading in the House of Commons. It suffered the fate of many other useful measures and was not even discussed for want of time. A Bill to restrict the practice of dental companies was dealt with simultaneously with this one in the House of Lords. Strong opposition was offered to it in the Select Committee by unregistered men and it did not succeed in reaching a third reading stage in the House of Lords. Amongst the Bills which were introduced into the House of Commons and subsequently dropped were the Municipal Milk Depôts Bill, the Nurses' Registration Bill, the Parochial Medical Officers (Scotland) Bill, the Poisons and Pharmacy Bill, the Public Health Officers Bill, the Purity of Milk-supplies (Scotland) Bill, and the Sale of Whisky Bill. During question time since the session began matters affecting cases were treated with large doses of iodides, and iodine and hydrogen peroxide locally.

FREQUENCY OF ACTINOMYCOTIC PERITYPHLITIS.

Grill mentions 77 cases as recorded up to 1895. In 1904 Löwe of Greifswald referred to 68 cases, but as he only gives the names of a few of the original publishers it is impossible to say how many are included both in his list and in Grill's. I have found 27 cases described since Löwe's paper appeared and it is probable that the total number is about 150, of which 27 are English. This is very far from representing the real frequency of the condition. Many cases have been recognised but have not been published. It is highly improbable that the nature of the disease will be realised unless search is made for the granules, and even then they are frequently absent from fæcal or chronic sinuses in undoubted cases. At St. Bartholomew's Hospital, of 650 affections of the right iliac fossa seven were due to actinomycosis. At the Bristol Royal Infirmary, of 380 cases diagnosed as appendicitis five were proved to be due to actinomycosis. In each hospital, therefore, the proportion is between 1 and 2 per cent., but for the reasons given I am confident that this greatly under-estimates the real frequency of the condition. That most of the writers on the subject have seen two, three, or more cases, and that they represent England, France, Germany, Austria, Sweden, Italy, the Argentine, the United States, and Canada, suggests that it is a widespread affection and not so uncommon as the records would suggest.

ETIOLOGY.

Sex.—Of 68 cases described by Löwe 49 were male and 19 were female. Of 20 cases recently described in England 13 were male and seven were female. Therefore the proportion is about five male to two female.

Age.—Using the same records we find :—

Between	0-10	years of age	0 cases.
,,	10-20	,, ...	15 ,,
,,	20-30	,, ...	21 ,,
,,	30-40	,, ...	18 ,,
,,	40-50	,, ...	15 ,,
,,	50-60	,, ...	7 ,,
,,	60-70	,, ...	4 ,,

We notice that after puberty every age is equally liable, from which it of course follows that the disease is most frequently seen between 20 and 30 years. Young children escape ; I do not know of any instances younger than 14 years.

Occupation.—A large number of the sufferers are in some way connected with farm life or deal with corn.

Foreign bodies, apparently carrying the infection, have been found in at least five cases, two of which are recorded in this paper. The substances in question have been a small husk of corn (Illich), a husk of barley (Ammentorp), a pin, and a blackberry thorn. Cuff has described an actinomycotic abscess of the abdominal wall about a wheat husk which had escaped from the ascending colon.[1] In Regnier's case a foreign body was imbedded in the tumour but its nature could not be determined.

Nature of the invading organism.—As has been pointed out by Kellock, it is probable that in some cases what have been described as actinomycetes are in reality another form of streptothrix. In my three cases clubs were distinctly visible.

PATHOLOGY.

Organ affected.—According to Poncet and Berard 60 per cent. of cases of actinomycosis of the abdomen have their origin in the right iliac fossa. In many instances it is never possible to discover the exact site of invasion. Of 21 cases tabulated by Löwe in which a definite statement was possible 16 started in the appendix and five in the cæcum. Of 13 cases since described ten started in the appendix and three in the cæcum (all three described by Waring). The proportion is therefore about 3 to 1.

Nature of the original lesion.—It is seldom that opportunity arises for determining this. Most usually a small ulcer forms in the mucous membrane, which tends to spread and deepen and is surrounded by a congested area. In this the mycelium has been detected microscopically (Dieulafoy, Kelly, Godlee, and others). In other cases small nodules in the submucous coat may be seen projecting through pigmented mucous membrane which later soften and ulcerate through (Koranyi). In a case described by Thédenot (quoted by Kelly) a slightly swollen appendix was removed when an interval had elapsed after an attack of acute appendicitis, and later the disease appeared in the stump.

Spread.—Three types are described. 1. The mucous membrane may be very extensively ulcerated, forming the principal if not sole localisation of the disease (Chiari, Canali, quoted by Daske). 2. The wall of the appendix and cæcum may be greatly thickened without perforation or extension (two cases described by Hofmeister). 3. Perforation is the usual sequence. Acute general peritonitis does not result, but abscesses form and track freely in all directions, enclosed by adhesions of very extraordinary density, more so than in any other abdominal condition. In one of my cases the peritoneum was half an inch thick.

Further spread takes place by *continuity* and by vascular *metastasis*. As regards continuity the number of directions in which the pus may track is extraordinary. Not uncommonly the disease progresses at one point and retrogresses at another, and long radiating indurated scars leading from the appendix to the transverse colon or liver may be left. The following are sites where abscesses may form or point by direct extension : amongst the muscles of the abdominal wall (as in two of my cases) ; in the loin (three of my cases) ; at the umbilicus (two of my cases) ; on the left side of the abdomen (in Gangolphe's case it originally presented in that situation) ; in the hypochondrium ; as a subphrenic abscess (two of my cases) ; in the lungs, pleura, and chest-wall (two of my cases) ; in the groin, buttock, or hip-joint (Grill and others) ; or as a perirenal abscess on the right side. It may involve the bladder and ureter (Ammentorp), or an abscess may burst into the bladder (Boström, Hesse, Billroth) or rectum (quoted by Löwe), or erode the lumbar vertebræ (three cases quoted by Löwe). Benda and others have described secondary thrombosis of the inferior vena cava. Metastasis is principally in the liver where abscesses are very common and may attain a large size. They are often of a spongy character rather than well-defined cavities. Kellock has described a case with abscess of the pancreas.

Secondary infections.—It is very common for the sinuses and abscesses to become fæcal. Exhaustion from septicæmia is the usual cause of death. Albuminoid degeneration often occurs.

SYMPTOMS.

Hinglais's description may be followed.

1. *Initial period of visceral manifestations.*—This consists of vague pains in the right iliac fossa, sometimes associated with intractable diarrhœa. This may be muco-membranous in type (Ransom, Partsch, Langstein). The pain may be severe and relapsing appendicitis will probably be diagnosed. There are no local signs. One case died in this stage after 24 hours (Sokoloff).

2. *Stage of tumour formation.*—The characters of this stage are described in the next section.

3. *Stage of fistula formation.*—Abscesses burst or are opened in the neighbourhood of the original site and dark fœtid pus discharges. In this the granules may be found but they are very often absent, especially if the discharge is fæcal. The best time to look for them is when a new abscess is opened. This stage usually lasts for months, subphrenic or pulmonary abscesses form, and the patient dies from hectic fever and exhaustion. In some cases, however, there is—

4. *A stage of cicatrisation.*—The fistulæ close and cure results. Unhappily this is often only temporary.

DIAGNOSIS.

Before perforation has occurred, with the formation of a tumour, the diagnosis can only be made by finding actinomycetes in the stools. This has been done by Ransom. I have found the ray fungus in the motions of a patient with abdominal actinomycosis, not of the right iliac fossa. When in a patient over 14 years of age there is a history resembling appendicitis and a large, very hard mass adherent to the deep structures and to the abdominal wall is felt in the right iliac fossa, but the temperature is not high, the pain is slight, and there has been little or no vomiting, actinomycosis should be strongly suspected. On such a clinical picture, added to the fact that eight years previously plastic adhesions had been found about the appendix, I diagnosed actinomycosis in my last recorded case, and at the operation this proved to be correct. If in addition the skin is œdematous, thickened, shiny, and of a purplish-violet tint the probabilities are very great. Further, when after operation for appendicitis massive adhesions are found and secondary abscesses and fistulæ continue appearing for passed. Without that withdrawal of opposition it would have been impossible to get facilities from the Government for the Bill.

---

[1] Brit. Med. Jour., July, 1906, p. 137.

Colonel SEELY seconded the amendment.

Mr. JOHN BURNS said that the Government reluctantly accepted the amendment in order to get the Bill through. Personally it was a matter of great regret to him that a great and honourable profession which associated itself with signal earnestness from the commencement with the movement for the reduction of infantile mortality, should now dissociate itself from what he conceived to be one of the most beneficent movements they had witnessed in recent years. Through their representatives in the House the medical profession had asked to be excused from coöperating with other people in this measure. He believed, however, that the best of the medical men would deplore the attitude taken up by their profession and would refuse to dissociate themselves from the rest of the people in working this experimental measure. He was convinced that the medical men were greater than their trade union and would take a wider view than their profession imposed upon them. When this Bill had had a year's experience he was certain that medical men would agree to take an active and practical part in its working.

Mr. COOPER declared that the opposition of the medical profession was not on the ground of the non-payment of a fee for notification. It was the penalty to which they objected. When a deputation waited on the right honourable gentleman on the subject Sir Victor Horsley put it plainly and distinctly that it was the penalty which they objected to for failure to make the notification.

Lord ROBERT CECIL: The honourable Member must surely have forgotten some of the conversations we have had.

Mr. BURNS: Hear, hear.

Mr. COOPER continued that the medical profession regarded notification as a civil duty which should fall on the parent. The Bill was based on the Notification of Diseases Act. There was a penalty under that Act but there was also a fee. However, in this case the ground of the opposition of the medical profession was not the non-payment of a fee but the penalty which it was proposed should be put on the medical man in a matter which ought to concern the parent alone.

Several Members opposed the amendment.

Mr. BOWLES asked whether the rejection of the amendment would lead to the withdrawal of the Bill.

Dr. MACNAMARA, whilst admitting that the function of the medical man in the birth chamber was a professional one and that it was not for him to scatter broadcast notifications of births, thought that medical men might have undertaken this duty. He would not say that if the amendment were rejected the Bill would be dropped. However, he had been informed that if the amendment were not carried, and the duty of notification were cast upon medical men there would be such powerful opposition to the Bill in the House of Lords as would endanger the progress of the measure at so late a period of the session. He felt that with the medical men out of the Bill it was still worth saving and he hoped that the objections to the amendment would not be pressed.

Lord ROBERT CECIL, by leave of the House, made a personal statement with regard to his action with respect to the Bill. He, as the Member who had introduced the Bill, had been told that unless medical opposition to the Bill were withdrawn the Government could not see its way to grant facilities to it, by "starring" it on the notice paper. He therefore had approached the Government to see if it would assent to an amendment of the kind he now proposed. The representatives of the medical profession in the House agreed to withdraw their opposition if he moved such an amendment and if it were accepted by the Government. In those circumstances, if his amendment was not carried he would feel bound to prevent the Bill from going further if he could. He considered that the Government was also bound by that understanding, and, therefore, if the amendment was rejected it was honourably bound to abandon the Bill.

Mr. COOPER remarked that he had withdrawn his opposition to the Bill on the understanding that the Government would agree to the insertion of Lord Robert Cecil's amendment.

Mr. BURNS admitted that the noble lord had accurately stated the arrangement made between himself and the medical profession. They could not, however, by an amendment or bargain between themselves withdraw the Bill from the purview of the House when there might be a chance of getting it through. For his own part he declined to accept the attitude in which Mr. Cooper wished to place him. It was all very well to say that the medical men now did not want a fee. Had the honourable Member told that to the noble lord and himself before the necessity for a bargain of the kind would not have been necessary. He appealed to the noble lord to exonerate him from any breach of an agreement and to leave the matter to be determined by the good sense of the House.

Lord ROBERT CECIL intimated that personally he felt bound to adhere to the obligation he had come under.

Mr. COOPER then asked the noble lord to give way on this point and he for his part would raise no objection to the House passing the Bill in its present form. However, he would like it to be understood that when he withdrew his amendments to this Bill it was on the distinct understanding that the Government should "star" the Bill as a Government measure. If he had not withdrawn his amendments the Bill would not have been "starred." Therefore the onus would rest entirely with the President of the Local Government Board.

Mr. BURNS thanked Mr. Cooper for the promptitude with which he had withdrawn his objection and for the manner in which he had released Lord Robert Cecil and himself from any supposed understanding.

Sir HENRY CRAIK said that he was placed in a very awkward position as he had had no opportunity of consulting his constituents. No notice had reached him with regard to the fee. The only thing was the objection to a severe penalty attaching to the neglect to make notification. At the same time if Mr. Cooper, speaking for the medical profession, felt himself at liberty to release them, he was willing to follow his lead, though he confessed that he did so with doubt and hesitation.

On a division there voted—for the amendment, 19; against, 87; majority against, 68.

The amendment was accordingly rejected.

Clause 2 relates to the adoption of the Act and the definition of the local authority.

On the motion of Mr. COOPER an amendment was agreed to, providing that in London the medical officer of health of every metropolitan borough (including the City of London) in which the Act was in force for the time being should send weekly to the London County Council in a form prescribed by the Local Government Board a list of all notices of births received by him under this Act during the past week.

The report stage having been disposed of,

Mr. G. WHITELEY (Patronage Secretary to the Treasury) moved that the Bill should be read a third time.

Mr. COOPER regretted that the Bill had been deprived of its compulsory character in Committee.

Mr. BURNS, in supporting the third reading, said that there were many cases of infantile mortality and the milk-supply was a prime factor. He hoped that the President of the Board of Agriculture would tackle this subject next session. Married women, he continued, ought not to work in factories. Their province was at home. The sooner they recognised that the better for the comfort of their husbands, the health of their children, and the welfare of the State. Fortunately they were now confronted with a healthy public opinion on this matter and social feeling was rising in the direction of greater attention being paid to the care of the children. He hoped that the Bill would help to reduce the infantile mortality, which was a shame and reproach to the country, and that five years hence its success in this direction would make them say that they "builded better than they knew."

The Bill was read a third time amidst cheers.

The Medical Inspection of School Children.

Sir WILLIAM COLLINS asked the President of the Board of Education whether under the Education (Administrative Provisions) Bill there was any obligation on parents to submit children attending public elementary schools to medical inspection, as well as an obligation upon local education authorities to provide for such medical inspection.—Mr. McKENNA replied, by written answer: In the view of the Board the obligation placed by the Bill upon the authority to provide for inspection does not of itself compel a parent to submit his child to inspection.

TUESDAY, AUGUST 27TH.

Deaths from Privation in London.

In answer to a question by Mr. SUMMERBELL, Mr. BURNS furnished the following written reply: I understand that the number of cases is as follows: in London, 49; in the eastern district of London, 13; in the Whitechapel union, seven. This was the union in which the greatest number of deaths of the kind referred to took place. The number of cases in which coroners' juries returned a verdict of death due to want, exposure, &c., outside London was 171.

The Sleeping Sickness.

Mr. REES asked the Under Secretary of State for the Colonies whether he could state the weekly number of deaths from sleeping sickness in Uganda, and whether the Government would take special measures to prevent the spread of this scourge southwards to Nyassaland.—Mr. CHURCHILL replied: I regret that I am unable to give the information asked for in the first part of the question. The question of the measures to be taken to prevent the spread of sleeping sickness is not one for this Government alone, but for all the Governments in whose African possessions the disease unfortunately exists, and the only prospect of dealing with it effectively appears to be by international coöperation. The International Conference which met in London in June last has already taken some steps in this direction, and when it meets again in November next it is hoped that it will be possible to arrive at a definite agreement on the whole question of the investigation and control of the disease. I should, however, add that the problem of controlling an epidemic of this kind affecting vast areas in the heart of Africa is one which presents enormous difficulties, and that while every exertion will be made too much must not be expected even from international coöperation.

diagnosis was now influenza or enteric fever complicated by meningitis and one of us again saw the patient on the afternoon of this day. She was a well-nourished girl. She was not fully unconscious and put out her tongue when told to do so, but was unable to answer questions other than the very simplest ones. She resented any passive movement of her head, especially any forward bending of it, which caused great pain. No definite paralysis of the arms and legs could be detected apart from her weakness and drowsiness. There was considerable tenderness of the legs but they could be moved without much pain so as to test for Kernig's sign which was slightly present on the right side but not on the left. Examination of the ears showed some congestion of the membranes with serous effusion but no suppuration. The pupils were dilated and equal with a sluggish reaction to light. There had been no complaint of any numbness or alteration of sensation and she was not conscious enough for any careful testing of the sensibility. On the evening of this day (April 13th) she was removed to the General Hospital, Birmingham, a distance of some two miles, and on her reception there it was found that there was complete paralysis of both legs with flaccidity and complete anæsthesia below the umbilicus except on the outer side of the left leg. On the left side the knee-jerk was absent and the plantar reflex extensor. On the 14th she was in much the same condition, semi-delirious, but at times was able to answer questions rationally. There was no paralysis of the arms and the grasp was good on both sides, and sensation was good above the ninth dorsal segment. On the 15th the arms became paralysed and the respiration suddenly began to fail, ceasing within an hour from the first onset of dyspnœa and cyanosis. The heart was acting well five minutes before the cessation of the respiration, but it ceased beating two minutes later in spite of artificial respiration.

The case clinically when first seen was to all appearance one of influenza complicated by meningitis and the acute ascending myelitis. The positive Widal's reaction seemed in all probability to be an error. In the General Hospital some days later the reaction was negative.

Necropsy.—The post-mortem examination was held on April 16th. The whole body was examined. There were some catarrh of the small intestine and some slight enlargement of the mesenteric glands but neither by the naked eye nor microscopically was any evidence of tubercle found. The liver, spleen, and kidneys appeared congested and the heart muscle was pale. On opening the dura mater the spinal cord was found to be slightly adherent to the pia arachnoid by means of a sticky exudate. The pia arachnoid throughout the cord was opaque and grey in colour. Some of the vessels appeared congested when cut across but as a rule they showed themselves on the surface as thickened white lines. The nerve roots were also thickened. The white matter of the cord, especially in the upper cervical region, was soft and almost fluid. The line of demarcation between grey and white matter was indistinct. The grey matter was pale and soft. Portions of the cord fixed in formalin were cut in paraffin and stained with various methods. Other portions after three days' fixation in formalin were treated according to Marchi's method. The following is a record of the microscopic appearances:—With regard to changes in the pia-arachnoid, there was a well-marked distension of the smaller vessels of the membranes and nerve roots, but the larger ones, both arteries and veins, showed a striking inflammatory thickening of their outer coat and in places also of the middle and inner coats. The thickening was due to the presence of large numbers of cells, chiefly large with a fair amount of non-granular protoplasm; there were also small round cells and a few polymorphonuclear leucocytes. In places the cells were so arranged as to form typical tubercle follicles and, rarely, giant cells were to be found in their centres. In other places the cells were seen to be in process of breaking down and forming areas of necrosis. Tubercle bacilli were to be found both in the cellular and in the necrotic areas but they were not numerous. There was also a well-marked cellular infiltration of the sheaths of the nerves, the cells being chiefly of the lymphocyte variety and penetrating between the individual nerve fibres. Marchi specimens showed well-marked degenerative changes in the nerve roots. Outside the vessels and nerves there was also a well-marked cellular infiltration of the membranes but an even more marked accumulation of a coagulated material which did not as a rule give the staining reaction of fibrin. In the meshes of these coagula there were large numbers of cells, a considerable proportion of which were polymorphonuclear leucocytes. As to changes in the white matter, there was a dilatation of the small vessels entering the cord and, in addition, a marked accumulation of cells, chiefly mononuclear, round them. There were also accumulations of inflammatory cells at the margin of the white matter independent of blood-vessels. There was some evidence of degenerative changes in the myelin sheaths of the fibres in specimens stained with haematein and van Giesen but in the Marchi preparations this change was found to be well marked and diffuse. As to changes in the grey matter, in suitably stained preparations the ganglion cells showed degenerative changes of all degrees. In Marchi preparations the fibres of the grey matter also showed extensive degeneration. The brain weighed 43 ounces. On removing the organ a marked accumulation of turbid fluid was found at the base. Some of this was drawn off with proper precautions and examined by cultural and film methods. Cultures were made on agar, blood agar, and on nasgar, but there was no growth in any of the tubes. Films stained by Gram's method and by carbol-thionin showed no evidence of any organisms. The cells present in the exudate were chiefly polymorphonuclear leucocytes and large endothelial cells. Films were not stained by the Ziehl-Neelsen method. This turbid fluid in the subarachnoid space extended over the cerebellum and up the Rolandic fissure on either side. On the vertex the vessels of the pia mater were injected but there was no obvious exudate. Nowhere were there distinct tubercles to be seen. The vessels of the pia arachnoid towards the base were pale as in the cord. With regard to the microscopic appearances, the cerebellum pia arachnoid showed infiltration with inflammatory cells, more marked around the vessels. There were a few giant cells and some caseous areas. In some places the white matter of the cerebellum was infiltrated with cells. The pons showed a similar condition with extensive infiltration of the pia arachnoid and implication of the white matter. Portions of the cortex from the Rolandic area on the left side and from the vertex on the right showed similar appearances but less marked. Microscopically the kidneys showed a condition of early catarrhal nephritis. The liver showed an acute hepatitis with cloudy swelling and separation of the liver cells from one another, also infiltration of the portal tracts and lobules with inflammatory cells. The intestine showed acute catarrh but in none of the organs were tubercle bacilli. Examination of the middle ears showed no evidence of inflammatory changes.

The above case is one of tuberculous meningitis and myelitis. Its chief interest pathologically is in the fact that to the naked eye the appearances were not suggestive of tubercle. There was no obvious point of entrance found, but too much stress cannot be laid on that, as one did not examine every joint and bone. At the same time, the case appears to be one in which the meninges were the point primarily affected, the changes in the nerve roots and in the white and grey matter of the cord being relatively insignificant and apparently secondary.

CASE 2.—This case, although one of acute cerebro-spinal meningitis of tuberculous origin, was clinically one of cerebral meningitis, tuberculosis being from the symptoms quite a probable diagnosis. The presence of double otitis media in this case raised the possibility of a local origin for the cerebral condition, and therefore an exploratory trephining was done but without definite result. The patient was a boy, aged seven years, who was admitted to hospital with frontal headache and vomiting, and a temperature of about 101° F., the illness having lasted seven days. This illness began with vomiting and pains in the head. He was not seen by a medical man till the ninth day and then his condition was so suggestive of enteric fever that he at once sent him to hospital. For the first few days in hospital no nervous symptoms showed themselves, except the headache and the vomiting, which was of cerebral type, and also absence of both knee-jerks. There were some bronchitis and symptoms suggestive of damage to the left lung resulting from a severe attack of pneumonia which he had when two years old. There was suppurative otitis media with perforation of the left membrane and the right ear showed signs of inflammation but no suppuration. On the fourteenth day of his illness twitching of the left arm and leg and left side of the face commenced and soon developed into a unilateral convulsion with only slight involvement of the right side. This was followed by unconsciousness and dilatation and inequality of the pupils. Kernig's sign and rigidity of the neck were also present and

KING'S LYNN, WEST NORFOLK AND LYNN HOSPITAL.—House Surgeon Salary £100 per annum, with board, residence, and washing.

LIVERPOOL INFIRMARY FOR CHILDREN.—Assistant House Surgeon for six months. Salary £50, with board and lodging.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Three House Physicians and Two House Surgeons. Salaries at rate of £80 per annum, with board and residence.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Assistant Resident Medical Officer for six months. Salary at rate of 50 guineas per annum, with board and residence. Also Assistant House Surgeon for six months. Salary at rate of £75 per annum. Also Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing.

MANCHESTER WORKHOUSE, Crumpsall.—Assistant Medical Officer. Salary £110 per annum, with *apartments, fire, light, washing, and* attendance.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon, for six months. Salary of two former at rate of £40 per annum, and of two latter at rate of £20 per annum. Also Resident Anæsthetist. Salary at rate of £40 per annum.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead.—Junior Resident Medical Officer. Salary £50 per annum, with board, lodging, &c.

NEWCASTLE-UPON-TYNE, CITY HOSPITAL FOR INFECTIOUS DISEASES.—Resident Medical Assistant. Salary £104 per annum, with board, lodging, &c.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, and washing.

READING, ROYAL BERKSHIRE HOSPITAL.—*Assistant House Surgeon* for six months. Salary £50 per annum, with board, lodging, and washing.

ROYAL DENTAL HOSPITAL, Leicester-square.—House Anæsthetist. Salary £50 per annum.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 a year, with board and residence.

SHEFFIELD UNION HOSPITAL.—Resident Assistant Medical Officer. Salary £80 per annum, with apartments, rations, and allowances.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary £40 per annum, with board, washing, and residence.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

TORQUAY, TORBAY HOSPITAL.—House Surgeon. Salary £100 per annum, with residence, board, and washing.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £50, with board and lodging.

WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Honorary Registrar and Pathologist.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Penkridge, in the county of Stafford; at Coldstream, in the county of Berwick; and at Lauder, in the county of Berwick.

Births, Marriages, and Deaths.

BIRTHS.

CLARK.—On August 28th, at Forest Hill, the wife of Charles A. Clark, L.D.S., of a son.

DAWSON.—On Sept. 1st, the wife of Bertrand Dawson, M.D., F.R.C.P., of Wimpole-street, W., of a daughter.

EDWARDS.—On August 28th, at Gosport, the wife of Lieutenant G. B. Edwards, R.A.M.C., of a daughter.

LYLE.—On August 30th, at Bournemouth, the wife of Lieutenant-Colonel Allan Lyle, R.A.M.C. (retired), of a daughter.

MACCARTHY.—On August 26th, at Londonderry, the wife of Brendan MacCarthy, M.D., D.P.H., of a son.

ROBERTSON.—On August 31st, at Wimbledon, the wife of Dr. F. W. Robertson, of a son.

MARRIAGES.

COMERFORD—WOODGATE.—On August 29th, at All Saints' Church, Patcham, Sussex, Beaumont H. Comerford, M.D., D.P.H., to Elizabeth, daughter of the Rev. R. Shaw Woodgate.

MCKINNEY—STEVENS.—On Sept. 2nd, at St. Barnabas, Little Ilford, Hugh Giffen McKinney, M.R.C.S., to Louie, daughter of Andrew Stevens.

SPRAWSON—KNOX.—On August 31st, at Holy Trinity Church, East Finchley, Evelyn Charles Sprawson, M.R.C.S., L.R.C.P., L.D.S., to Evelyn Jessie, daughter of John Knox.

DEATH.

MORE.—On Sept. 2nd, at Rothwell, near Kettering, James More, M.D., aged 73 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE INCREASE IN THE SALE OF SECRET AND PROPRIETARY REMEDIES.

MR. J. COFMAN, Ph.L., who is a strong advocate for reform in the pharmaceutical world, has recently read before the Federation of Local Pharmaceutical Associations a trenchant paper in which he urges pharmacists to set their house in order if they do not wish their proper business to be entirely swamped by the trade in proprietary preparations in which they are yearly becoming more deeply involved. After telling his audience roundly that the title of "chemist" is now merely an up-to-date euphemism for the French "bazaar" or the American "store," he remarked that "to stock and sell quack medicines is a disgrace for a respectable profession." He considered the advertised pharmaceutical proprietary preparations to be a menace to the present interest and the future existence of pharmacy, which he "dreams of" as flourishing brightly among the respected *professions* of England. The last part of his paper was concerned in showing that the profits *accruing to* the pharmaceutical chemist from the sale of these preparations in no way compensated *him for the loss of his old legitimate* profits due to the fact that some medical men, who look upon pharmaceutical chemists as responsible for the competition from quack medicines, keep back *dispensing from* them as a hostage until they have ceased helping the sale in these articles. Mr. Cofman put forward six proposals with a view to the checking the existing evils, the first two being "that the Pharmaceutical Society and the General Medical Council be approached to take such *steps as are in their* power to secure legislation for the proper control of the traffic in secret *remedies*." *He* then proposed the *following* motion:—

> "The Federation of Local Pharmaceutical Associations strongly convinced that the present unrestricted and uncontrolled traffic in secret remedies is fraught with grave dangers to the public health and is highly detrimental to the moral and material development of pharmacy, urge the *President and Council* of the Pharmaceutical Society to take such steps as are in their power *to induce His Majesty's Government* to introduce at an early date proper legislation for the effectual control of the said traffic."

Mr. Gadd moved as an amendment:—

> "That it be remitted to the local associations to consider what steps may be taken in the interests of public health to restrict and control the rapidly increasing traffic in secret preparations recommended by public advertisements as medicinal remedies, and to report."

This was carried unanimously. The matter is evidently not to be allowed to rest, for in reference to Mr. Cofman's paper a meeting is to be arranged in October between the General *Purposes* Committee of the Pharmaceutical Society and a select committee of the Western Chemists' Association of London, of which we understand Mr. *Cofman* will be a member. We trust that this conference will result in a strong case being made *out for* early *legislation* in the matter, although it is hardly likely that the statutory control of the sale of quack *medicines will be readily obtained. The public* dearly love mysterious remedies, but if they were informed by the label on every bottle of, let *us* say, the "*Happy Home Drink Cure*," that each dose contained a grain of *potassium bromide* and a few grains of milk sugar, they might hesitate in expending half-a-crown on a half-pint bottle.

IMPOTENCE IN THE MALE.

To the Editors of THE LANCET

SIRS,—Can any of your readers refer me to any literature on the subject of impotence in the male? I wish to know what to do in a case. It appears to me that, *judging from* what I have read, very little is known *for* certain on the subject.

I am, Sirs, yours faithfully,

August 28th, 1907. LITERA (M.B.).

THE POLLUTION OF FOOD.

A CORRESPONDENT writes:—"Entering a local post office, which is also a baker's shop, this morning I saw a number of females arranging cakes and pastry on trays. A girl of about 14 was sorting out a kind of cheese cake and during the process sneezed twice. The result of this physiological process on the cakes may be easily imagined, but all traces of the accident were speedily removed by the girl who carefully smoothed each cake with her fingers. This was done in the presence of the wife of the proprietor without a word of reproof. The proprietor of the shop was until recently a borough councillor." Practices more disgusting than this no doubt take place every day, and it is difficult to see how those who prepare and sell food can be made to realise their moral responsibility in the matter. While, however, such things take place tradesmen must not complain if they find irksome the laws which are made from time to time in the interests of the health of the public.

was 91, and these with the local condition made me diagnose the case as one of diphtheria. He showed no other signs of disease, especial attention being paid for those of syphilis. He had had no vomiting, declared he had suffered from no similar attack and knew of no others with a like illness. I gave orders for the man to be isolated at once in a tent and was much surprised at the indifference with which the Egyptian medical officer, who had had considerable experience in the Soudan, looked upon the case. On questioning this officer he stated that he had often seen such throats, that they were only slightly infectious, and that they were not diphtheria, indeed that diphtheria is seen but rarely in the Soudan. However, in spite of this the soldier was isolated. The urine was examined and found to be acid, of specific gravity 1020; albumin amounted to ⅛th but no sugar was found; microscopically some red and white corpuscles were seen but no bilharzia. The presence of the albumin made me still more convinced about the correctness of my diagnosis. Several slides were made from a swab and on examination presented much necrosed tissue with leucocytes, an enormous number of spirochætæ, many bacilli fusiformes, and a very few cocci, some in chains, some in clusters. There were no diphtheria bacilli. Some more slides were made and stained by the following methods: (1) Methylene blue; (2) Leishman's stain; (3) carbol-fuchsin; and (4) Neisser's stain. One film was stained with warm carbol-fuchsin for 20 minutes, decolourised with 1 per cent. sulphuric acid, and counter-stained with methylene blue, with the result that some free round or slightly oval bodies with a few oval, clearly defined masses in the bacilli fusiformes retained the carbol-fuchsin, though all the rest was thoroughly decolourised and took up the methylene blue satisfactorily; these bodies stained as, and had the appearance of, spores. Vincent found no spores, though many vacuoles, in the bacilli; however, I firmly believe that genuine spores were present, but the matter requires further investigation before anything definite can be stated. Cultures on agar smeared over with serum were made but showed no diphtheria, and the spirochætæ were in various stages of degeneration and disintegration. The blood appeared normal, there was no leucocytosis, and no bacteria or spirochætæ were found in the films examined.

The patient was given an aperient and an iron tonic, and the ulcer was locally treated by swabbing with carbolic 1 in 20 three times daily, a potassium chlorate gargle also being used frequently. On the following day the temperature was 99° and the local condition had improved. The patient had no further elevation of temperature and was quite convalescent after five days, when he was discharged back to his battalion. The urine on discharge showed no trace of albumin and no bilharzia had been found during his five days' stay in hospital.

In all the other cases the membrane had the same thick yellowish-white appearance and left a ragged bleeding surface on removal. All healed readily under appropriate treatment, except one ulcer opposite the last molar tooth which, there were reasons for thinking, was not having proper attention paid to it, for when the swabbing was properly and energetically carried out, the ulcer healed within a week.

In the cases where the tonsils were affected the temperature was only raised to 100°–101°, while in the subjects with ulcers in the mouth the temperature only reached 99°–100°, probably due to the part being less vascular and so the absorption of toxins was less pronounced. Albumin was present in two out of the three cases where the membrane was situated on the tonsils but was absent in those situated on the buccal mucous membrane. The ulcers around the last molar were not associated with decay of that tooth and in all the cases dental caries was slight or absent and the teeth were in a clean condition. The cases of tonsillitis occurred separately and must be, I think, very slightly, if at all, infectious. There was a slight epidemic of follicular tonsillitis, 12 men, all coming from the same barrack-room, reporting sick one morning, but though several cases were examined microscopically I could find neither spirochætæ nor bacilli fusiformes, only many cocci such as one meets in the ordinary cases of follicular tonsillitis.

The spirochæta differs from the spirochæta pallida in the following points: (*a*) it readily stains after from two to five minutes; (*b*) it is considerably thicker and bigger; and (*c*) it has fewer and coarser curves, which usually number from three to six. The length varies from 15 to 25 or 30 μ, the ends are tapering, and it is perhaps the spirochæta buccalis. Some individuals seemed to be undergoing transverse fission but none showed any signs of longitudinal division. I could not distinguish any signs of an undulating membrane but some had one or more dots apparently chromatin. The spirochætæ were not only found on the surface of the membrane but also in the deeper layers after it had been removed, though present in fewer numbers.

These cases occurred during the hot weather and no cultures were attempted except a few on agar smeared with serum, which were kindly incubated for me by Dr. Andrew Balfour at the Wellcome Research Laboratories; in none of these were diphtheria bacilli found and the spirochætæ showed no signs of further development but were degenerated and undergoing disintegration. The spirochætæ were associated in all cases with the bacillus fusiformis, and this is worthy of note in that the same combination is frequently found in primary syphilitic lesions, in pyorrhœa alveolaris, and in Vincent's angina.

Though careful search was made for the bacilli changing into spirochætæ the only points noted were that a few bacilli had the chromatin mass at one end and the blue body seemed drawn out into a long tail which took up the red colour with Leishman's stain; further, some bacilli seemed more or less degenerated with the chromatin more or less scattered and in these cases the bodies tended to take up the red colour rather than the blue. Whether there is any direct relationship between these two or only a condition of symbiosis has yet to be definitely decided.

Besides the cases already mentioned there were three others with similar membranous ulcerations in the conjunctival sac occurring mainly on the parietal membrane, and all, without exception, in the lower sac. These cases were not included in the list, for although smears were taken and set aside only one slide was examined, and that casually, and found to contain spirochætæ in profusion, while the others were unfortunately mislaid and lost owing to my having to leave Khartoum suddenly and on my return I was unable to find them. However, although spirochætæ were present in one (whether associated with the bacillus fusiformis I cannot remember), yet I fully believe all the others had spirochætæ, as the membrane had the same characteristics, thick, yellowish-white, which on removal left a bleeding surface—to the naked eye entirely like the conditions already described. Unfortunately, the urines of these cases were not tested.

II.—INTRACTABLE, SLOW-SPREADING, DESTRUCTIVE ULCER OF THE PENIS.

Three such cases have come under my observation, one going on to the complete destruction of the penis, the other two to considerable loss of substance (from 1 to 2 inches). All the cases occurred in Soudanese. The ulcers were large (the smallest at least of the size of a shilling) when the patients came under treatment and were situated on the glans penis or in the preputial fold. The first case was under the treatment of Captain S. L. Cummins, and I only saw the end of the disease after practically the whole of the penis had been destroyed; the other two cases were under my own care.

The ulcers had no covering slough, exuded a serous fluid, which was, however, at times slightly purulent; the edges were slightly undermined, though here and there raised, and the bases were indurated to a slight degree. They were practically painless, the lymphatic cords were not thickened, and the inguinal glands were but slightly enlarged. The patients showed no signs of syphilis, and although in hospital for several months exhibited no signs of this disease in spite of having no anti-syphilitic treatment.

The first case that I had from the beginning under my own observation was considered to be simply an enlarged, neglected, soft sore, but finding that week after week, in spite of all kinds of treatment, the ulceration steadily spread, destroying the surrounding and underlying tissues, including the urethra, it was found necessary to reconsider the diagnosis. Smears from these two cases were examined on several occasions, sometimes taken from the surface, sometimes after the superficial tissue had been scraped away, and were found to be composed of necrosed tissue, many cocci, mainly diplococci, and a large number of bacillus fusiformes. There were no bacilli giving bipolar staining similar to Ducrey's and no spirochætæ were found. There was no Giemsa solution, but "pallida" was stained for by prolonged Leishman's staining.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Daily Dispatch, Manchester City News, Grantham Journal, Liverpool Post, Yorkshire Post, Reading Mercury, East London Observer, &c.*

result of the investigation showed almost identical results for the two diseases. Amongst those aged five years and under none were found "regular." Amongst those over 25 years of age none were found "irregular."[*] In the age periods between 5 and 25 years the irregularity decreased in proportion to the age, but of the two diseases the greater frequency of irregularity was actually exhibited by the scarlet fever cases.

Several cases of diphtheria and scarlet fever in the first age-group were found to have had only very slight irregularity.

This practically equal result, then, from two diseases with widely different cardiac effects suggests the exclusion of the heart as a factor in the causation of this sign. Further, the occurrence of the sign will be found to be little more than physiological in its significance; in the bulk of cases this irregularity is the *regular variation in force* and frequency of the pulse to which the term "*pulsus paradoxus*" is applied by some authors, occurring in healthy adults only on forced inspiration and expiration, but tending to occur frequently in apparently normal children, especially when asleep. This respiratory irregularity of pulse was met with in every degree; from the just perceptible variation of rhythm up to instances where the pulse-beat occurring as expiration begins, hangs—as if failing the due arrival of another inspiratory effort the heart must stop altogether; the ratio of the number of beats during inspiration and expiration being more than 3 to 1 in these cases.

A brief inquiry into this phenomenon is necessary in order to show that there is really nothing specifically cardiac in its causation. It is fully discussed by Wenckebach[6] in his work on "Arhythmia of the Heart"; he concludes, with Lommel, that "*this phenomenon is clinically, as well as experimentally, purely of nervous origin; for it is not a typical symptom of any organic disease of the heart, but it is one of neurasthenia; at the same time we do not mean that it cannot occur in cardiac disease.* We are bound to *assume the cause lies in an excessive susceptibility* in the inhibitory centre of the vagus." As regards "the mechanism by which *this is produced—the most* likely view is that the rhythmical stimulation of the respiratory centre has a rhythmical effect on the vagus centre, so that as the respiratory centre becomes active, the tone of the vagus centre is diminished and *vice versâ.*" Sir James Barr,[8] on the other hand, in a recent article specially dealing with this subject, believes *the solution* rests on a less hypothetical foundation. He finds a sufficient explanation in the mechanical effect of the respiratory act upon the circulation. "The pulsus paradoxus is due to one or both of the two following causes, namely, defective filling or rapid emptying of the *arteries. In the* former case a weak right heart and a *large lung reservoir* are important factors, and in the latter a good respiratory *pump and low blood pressure* are the causal agents." With *this explanation* it can be understood that this irregularity may occur in health. For example, other factors being *normal, an exceptionally* well-developed chest and lungs may be *sufficient to produce it. In disease* doubtless it is the other factor which is the all-important one—the fall in blood pressure. Wenckebach's remarks on neurasthenia will also fit in *here, for in that condition* or, better, in a state of asthenia *we have the same thing*—a relaxed condition of the body and vessels. The *phenomenon* is, however, sometimes so capricious in its appearance and disappearance that one feels tempted *sometimes to give it the obscure* functional nerve origin suggested.[11]

In carefully following, *then,* about another 100 cases that recovered in each disease, the *irregularity before noticed* was found to be *almost constantly respiratory.* A distinction must then be drawn between this *respiratory* and what may be termed "*true*," *irregularity,* which latter undoubtedly occurs in diphtheria. For amongst the cases ending fatally in this disease many exhibited true delirium cordis for a few hours up to several days before death. Leaving this part of the subject for the time being we will turn to consider what percentage of true irregularity may be found in non-fatal cases. In the first place we might include a few cases of delirium cordis, if it be allowed that it is not invariably in the early weeks of the disease a sign of a fatal issue. There were, however, no instances in the hundred cases examined. Later in convalescence, nevertheless, it may occur along with dilatation from accidental strain, but soon passes away in favourable cases. There were, however, a few cases with marked respiratory variation which appeared to have an added tendency to irregularity apart from this; and these might also be included. Still, a judgment on such a matter should not be too hastily given, for it is surprising how easily one may mistake a case of well-marked respiratory irregularity for one of true arhythmia. In making an observation the eyes should always be fixed on the chest and the respiratory *movements carefully* noted along with the *changes in the* pulse. *Even* where the respiratory variation is the only irregularity present, the effect is *often* a very *confused one in a slow pulse. This is owing to the fact that where the* phenomenon is well marked there are two strong *tendencies* alternately supplanting *one* another, the one during inspiration *to quicken the pulse, and the other* during expiration to *slow it.* In changing over from one influence to the other there is a liability to a jumbling or hesitancy of rhythm, especially where the pulse intervals are not exact multiples of the respiratory periods. But towards the end of inspiration or expiration, or particularly if these are voluntarily prolonged, the pulse is found to have settled down to a regular beat, which again serves to show that intrinsically, as far as the heart *itself* is concerned, it is essentially regular, but owing to mechanical extra-cardiac causes there is one rate for inspiration and another for expiration. Other more curious *effects* are sometimes produced when both the *slowness of the pulse* and the tendency to respiratory variation are *very marked.* One little patient (a case of scarlet fever with *no obvious* cardiac lesion) exhibited a typical *bigeminal pulse* for some minutes, which after a time changed to a *trigeminal* one and then back again to the original. The paired beats coincided with inspiration and the pauses with expiration.

In this way the percentage occurrence of true *irregularity* in *non-fatal attacks may* be reduced to only a few *cases* in a *hundred—a small one* compared with that usually given. As regards fatal cases, which number about 7 per cent. of all,[1] delirium cordis perhaps occurs in more than half—i.e., before the patient is actually *in articulo mortis.* The total occurrence of true irregularity of the pulse in diphtheria will still, however, be less than 10 per cent.

When the above results were recorded in a *thesis on* diphtheria I was not able to obtain Villy's paper *previously* referred to on Vomiting and Cardiac *Failure in* Diphtheria. Since then I have gained *access* to it. He tabulates his results on the occurrence of cardiac irregularity in 177 cases. This table—with which *previously* I was altogether unacquainted—so strikingly resembles my own in all essentials and so *admirably* bears out my own contentions that it is also inserted for purposes of comparison. In the first place, the total percentages are alike—*over* 80 per cent. in both; but his inference *that* all this is to be taken in a general way as *indicative of a* tendency to cardiac *failure* is evidently *erroneous.* The

A Lecture

ON

THE COÖRDINATION OF POST-MORTEM WORK AND CLINICAL OBSERVATION.

Delivered at the Post-Graduate Course, Leeds Public Dispensary, on June 14th, 1907,

By E. F. TREVELYAN, M.D., B.Sc. Lond.,
F.R.C.P. Lond.,

PHYSICIAN TO THE LEEDS PUBLIC DISPENSARY; LATE PROFESSOR OF PATHOLOGY, LATE YORKSHIRE COLLEGE (VICTORIA UNIVERSITY); PHYSICIAN (WITH CHARGE OF OUT-PATIENTS) TO THE LEEDS GENERAL INFIRMARY.

GENTLEMEN,—A sound clinical knowledge of disease is impossible without a sufficient knowledge of the pathology of disease. Therefore the importance of bringing into close relationship the pathological changes found in the post-mortem room and our observations of disease made during life is obvious. At a time when the great advances in science have made it necessary that the teachers of pathology in our medical schools should give their whole time and attention to their subject it becomes of greater importance than ever that the clinical element should be kept constantly in view in the post-mortem room. For this reason I think it would be a misfortune if the post-mortem room were handed over to the pathological specialist as it is eminently the ground which should be occupied by those in close touch with clinical work, for the clinician learns by daily experience the needs and wants of those training to be clinicians. Of course, the aid of the bacteriologist, morbid histologist, and pathological chemist will always be required to supplement and confirm the post-mortem room findings. Such reports when received can be read out on a subsequent occasion and the case recapitulated and reviewed in the light of any additional information obtained. Naked-eye morbid anatomy as such can be learnt in the pathological museum now furnished with specimens which retain more or less perfectly their original colour, but morbid anatomy in relation to clinical work can only be satisfactorily learnt in the post-mortem room where the whole clinical and pathological aspects of disease can be coördinated. I decline to make a post-mortem examination where there are no clinical notes available, as I look upon it as almost waste of time.

Some 15 years' experience of post-mortem work has led me to adopt the following method of procedure. Before the post-mortem examination is made the clinical report is abstracted and the abstract is written on the blackboard in the post-mortem room. At the commencement of the examination this abstract is read out and the morbid changes which it is expected to find are outlined. The various morbid changes are then demonstrated and this is followed by a commentary on the pathological findings. Finally the symptoms are compared step by step with the pathological changes present. I need not say that the clinical diagnosis made during life is always regarded as the best that could be made in the circumstances, so as to permit of the freest possible discussion of details both clinical and pathological. Everybody with a tithe of clinical experience appreciates to the full the diagnostic difficulties that may arise in any case. Finally, it is almost needless to add that each post-mortem examination should be thoroughly made—that is, every organ examined, and for this reason it seems to me impossible satisfactorily to conduct more than one or at most two examinations at a time. In this demonstration I shall follow the order indicated above. Thus I shall first give a few clinical notes of the case. I shall then describe the specimens and make some pathological comments upon them. Finally, I shall endeavour to coördinate the morbid changes found after death with the symptoms present during life.

I.—Syphilis of the Trachea and Bronchi; Stenosis of a Bronchus.

The specimen came from a woman, aged 32 years, with an enlarged thyroid. A month before death when I saw her she had inspiratory and expiratory stridor, and diminished movement of the right side of the chest with a deficient air entry. Nothing abnormal was seen in the larynx. A diagnosis was made of pressure on the right bronchus, probably due to malignant disease. The specimen shows one large and several small ulcers in the lowest part of the trachea. There is also ulceration in the uppermost part of the left bronchus. The right bronchus is stenosed for about half an inch at its origin where it will only admit a small quill. The stenosis appears to be due to a sclero-gummatous process in the submucosa as no distinct evidence of past ulceration is visible. It does not therefore represent a more advanced stage of the ulceration seen in the left bronchus. The left lung was considerably larger in size that the right owing to hypertrophy. The left lung did not present any abnormal appearances. No evidence of syphilis was found elsewhere in the body.

Syphilis of the trachea and bronchus is rare. I have no recollection of meeting it before in the post-mortem room. Unless in association with laryngeal syphilis its site of predilection is in the lowest part of the trachea and upper part of the bronchi. If the disease extends to the bronchi it usually affects both of them. The reason of this localisation is unknown to me. Tuberculosis more commonly gives rise to ulceration of the trachea than syphilis and is found almost exclusively in association with laryngeal tuberculosis. There was no evidence of tuberculosis in the above case nor did the ulcers themselves appear tuberculous. The morbid changes met with here explain all the symptoms and signs present during life—the stridor, deficient-air entry, &c. Perhaps I ought to have made a more exact diagnosis during life, and no doubt it would have been wise to have given iodides in a case where the nature of the disease was involved in some doubt.

II.—Caseous Pneumonia; Tuberculous Laryngitis.

The specimens were obtained from a man, aged 25 years, who also had spinal caries and paraplegia (see Specimen VIII.). The pulmonary disease had lasted three months and was attended with cough and sputum, pyrexia, and some hoarseness. There were signs of consolidation at the right apex.

The right lung is solid almost throughout but the lesion is more marked towards the base. A lobular distribution is clearly evident in parts and some tubercles are present in the pleura. Scattered aggregated tubercles are seen in the opposite lung. The larynx shows a symmetrical ulcer on the posterior part of both cords and there is early but distinct pachyderma affecting the posterior laryngeal wall.

Caseous pneumonia, or broncho-pneumonia, represents one of the acute forms of pulmonary tuberculosis. Its distribution suggests very strongly an aerial infection. In this case there was no older lesion from which tuberculous products could have been aspirated as may happen in the more acute basic infection of the lung in some cases of apical pulmonary tuberculosis. There was, however, a focus of disease in the immediate neighbourhood—viz., in the tenth dorsal vertebra, and it is possible that the infection spread from this focus. It has been suggested, and I have seen at least one instance which seemed to bear out the view, that the lung may be infected from caseous bronchial glands in its neighbourhood without the latter directly communicating with the air passages. An interesting question might be raised as to the respective age of the laryngeal and pulmonary lesions in this case. The laryngeal disease certainly has the appearance of being the older but I have never yet seen a case of unmistakably primary laryngeal tuberculosis.

The symptoms are sufficiently explained by the morbid anatomy found, though here, as in many cases, the amount of disease present was much greater than might be anticipated from the signs. The laryngeal lesion produced hoarseness and if there had been any difficulty in the diagnosis of the nature of the pulmonary disease the examination of the larynx would have cleared it up. This bears out the statement that in cases of doubtful pulmonary tuberculosis it is well always to examine the larynx.

III.—Marked Atheroma of the Aorta, Coronary Arteries, and Splenic Artery; Great Hypertrophy of the Heart without Valvular Disease or Renal Disease.

The patient, a man, aged 50 years, had rheumatism when 24 years of age. He had presented steadily increasing symptoms of illness for the past seven years. Œdema of the legs appeared in August, 1906, and he gave up work in November. On admission in May, 1907, he was waterlogged. The apex beat was displaced outwards but there disproof of the contentions it was supposed to uphold. He apparently gives it as a typical instance of a diphtheritic pulse. It evidently belongs to the period we are discussing. The rate and regularity of the pulse were noted at short intervals of two or three hours throughout a 27 hours' period. The details are so fully given that little doubt is left but that it is no more than a case of respiratory irregularity in spite of the history of cardiac dilatation. The variation in rate from 120 down to 66 in the 24 hours is seen to be a more or less regular movement, consisting of one large wave and depression with a small reflowing wave at the intervening 12-hourly period. The pulse is marked "regular" at the maximum acceleration and "very irregular" at the minimum rate, with varying degrees of irregularity at the stages intervening. The same writer in another place shows that he also makes no distinction between the different forms of irregularity. In referring to the history of a former case he finds the pulse was irregular and on this concludes that the heart was specifically affected. No allusion has been made to the possible effect of a diseased vagus nerve in the earlier stages of diphtheria. Whatever effect it may have in producing true irregularity—though I believe the affection of the heart wall is the main consideration at this time—it has obviously no effect upon the frequency of occurrence of the pulsus paradoxus, as is evident from the above comparisons of different diseases and from the presence of the latter in health.

In most cases respiratory irregularity of the pulse in children persists throughout their stay in hospital—that is, for periods of from four weeks to as many months—especially in marked cases, although they have otherwise regained their normal state of health. There is, however, always a great tendency for it to grow less with the return to the normal vascular tone and, as might be expected, adolescents and adults are most likely to show improvement in this respect. Owing to the limitations of space I have refrained from giving instances of actual cases, numbers of which might have been produced to illustrate every point of this paper. I might add that from the knowledge of the capricious appearance and disappearance and persistence of respiratory irregularity of the pulse and from experience gained in hunting up old patients many months after discharge from hospital—cases of typhoid fever and scarlet fever, as well as diphtheria—I have much difficulty in taking seriously many of the cases described in the literature of the subject who are stated to have lost an irregularity of the pulse which they had exhibited during many weeks and months and on the disappearance of which they had been promptly discharged. I fear that many of these cases visited afterwards in their own homes would be still found with the same peculiarity of pulse for which they had been so long detained in hospital.

In conclusion, a proper understanding of this subject has an important bearing upon the prognosis and treatment of the disease. More than one writer has urged that the patient should be retained in bed for at least three months[7] if irregularity of the pulse continues. Should irregularity, however, be as unimportant as it has been shown to be in seven-eighths of all cases, it becomes rather a serious matter, economically and medically speaking, to keep a practically healthy child in bed for a month longer than is necessary, particularly as a condition of slight general asthenia is much more likely to disappear with exercise in the open air. Of course, it is none the less necessary first carefully to decide that the irregularity is no more than respiratory. The presence of cardiac signs will often help to decide this matter. Should these, however, be lacking, the pulse otherwise good and the patient apparently returned to health, he may be at once discharged, just as hundreds of such cases are discharged yearly from the various fever hospitals, assuredly none the worse for a due return to their normal state of life.

The results of observations upon patients in hospital are published with the kind permission of Dr. Philip Boobbyer, medical officer of health and superintendent of the isolation hospitals.

Nottingham.

RESULTS IN APPENDICITIS TREATED BY THE IMMEDIATE AND COMPLETE OPERATION.

By WALTER G. SPENCER, M.S. Lond., F.R.C.S. Eng.,
SURGEON TO THE WESTMINSTER HOSPITAL.

It is important to note that in spite of the prevailing severity of appendicitis a continuous reduction in mortality can be achieved by operating systematically as soon as a diagnosis has been made, with the determination to remove the appendix in all cases. In a series of 100 strictly consecutive cases up to Jan. 31st, 1905, which I communicated to the Royal Medical and Chirurgical Society at the discussion on appendicitis, the mortality was 15. In a similarly consecutive series of 100 cases ending June 13th, 1907, the deaths numbered seven. Of these three died in consequence of pre-existing disease whilst recovering after operation for an intercurrent appendicitis, leaving four deaths in which the diagnosis and operation were too late. There is this special value in the comparison of the two series: the great majority of the cases in both series was first seen and approximately diagnosed by the same practitioners. *The diminution in mortality is therefore to be accounted for by the earlier time at which these practitioners have found themselves able to make a diagnosis and to put the case under my care.* For all the 100 cases were thus transferred to me after diagnosis except *two nurses* with acute perforation. *This immediate operation has not* entailed errors of diagnosis; a bimanual examination in particular has determined the disease in the subacute cases, and in acute cases, when the appendix could not be felt, the signs of early septic peritonitis have been a sufficient indication for immediate operation.

The superiority of the immediate and complete operation is established not only by the series as a whole but by the cases individually. No amount of experience affords grounds for a certain prognosis, so that any delay in operating simply leaves the patient to chance. *Anything short of the complete exposure and removal of the appendix fails to reach the deepest focus of suppuration.* It may be taken as a rule that until the appendix has been shelled out septic pockets remain unopened. Consequently *in this series there have been no lingering cases except the fatal one* (6) in which all the extent of suppuration could not be reached at the operation.

A table of the 100 cases illustrates the greater severity of appendicitis in young subjects and in males:—

	Class I.	Class II.	Class III.	Class IV.
Total	37	31	14	18
Males	14	12	7	14
Females	23	19	7	4
Under 20 years	7	10	7	14
Under 30 years	33	25	10	16
Deaths	0	4	1	2

Class I.—Removal of the appendix and the complete suture of the abdominal wall. 37 cases; no deaths. No hernias or fistulas afterwards. These were either cases in the interval between the attacks or early acute and subacute cases in which it appeared that drainage might be dispensed with. All had disease of the appendix to some degree; no doubt some would have recovered from the particular attack without operation, others would have become rapidly worse had the operation been delayed. Beforehand one could not have distinguished them.

Class II.—Cases of acute septic peritonitis *following* gangrenous, perforating, and subacute appendicitis. Appendicectomy and suture of the abdominal wall except for a drain laid obliquely through the wall, removed after a day or two. The peritoneal cavity, the pelvis in particular, was sponged out; the septic fluid removed varied from 30 to 500 cubic centimetres, but the peritoneum generally appeared capable of still absorbing. 31 cases; four deaths. All the recoveries were complete, without hernias or fistulas.

Of the deaths:

(1) A male, aged 22 years, died on the *fifth* day after operation. The wound and lower part of the peritoneal cavity appeared to be healing well. There was an acute ulcer of the stomach with septic sub-diaphragmatic peritonitis. He was supposed to have had three *previous* attacks of appendicitis. The appendix at the operation was found

over the hair. It is advisable to put cotton-wool in the ears. The patients sit on stools or chairs. The lamp is not placed under the creasote until the patients are settled in the room, so that they get the vapour gradually mixed with the air. The average duration of a *séance* is half an hour; at first shorter, afterwards longer, possibly an hour or an hour and a half. The treatment is repeated as a rule every day but occasionally I have had it given twice a day. Bronchiectasis is the only condition which seems to derive benefit from it, but in that the benefit is usually very marked."

Coming now to the ordinary local inhalation, here again we see things undertaken much more thoroughly abroad. Each patient has his own private coupé, but the water, air, or steam is supplied to all from one source. Speaking generally, at the sulphur spas of Challes, Marlioz, Allevard, and Uriage pulverisation, or as we call it atomisation, of the water is the only method used. There are three varieties. The first is called "*brisement*," where the water is broken up by impinging on a metal surface. It is previously forced into a sphere under a pressure of 15 to 20 atmospheres; thence it comes with great force through a very fine agate or ruby nozzle with a lumen of one-fifth to one-tenth of a millimetre in diameter. The metal surfaces on which this fine jet forcibly impinges are of three kinds:—(*a*) A tambour. This is a small hollow cylinder about one and a half inches long and three-quarters of an inch in diameter. This cylinder is hinged on a metal stalk which in its turn is fixed into a solid earthenware foot some three inches in diameter. The jet enters one end of the tambour, is so directed that at the centre it impinges on the concave surface, is at once broken up, and issues in a cloud of the finest dust at the other end, the circumference of this end cutting off the outer portion so that a comparatively small, fairly cylindrical column of atomised water having a considerable velocity is the result. This tambour form is used for throat and bronchial inhalation (oral), as the whole of the column can enter the mouth without wetting the face. (*b*) A palette. This is a small disc of metal which replaces the tambour. It has a spray which radiates more widely than that from the tambour; it is used for skin eruptions, conjunctival or nasal troubles, and can be placed close to the diseased spot. (*c*) A tamis, or fine meshwork of platinum, through which the jet forces its way and is broken up in so doing. The resulting spray is a much coarser one than by either of the other methods and as far as I could see is not much used.

Another variety of inhalation is that where the fluid is drawn up and atomised by a jet of steam, a warm cloud of particles resulting; this is used a great deal at Challes and Uriage. Lastly, there is the variety so commonly made use of on a small scale in England where an *air* jet draws up and atomises the fluid. But with us the force of the air jet depends upon a small rubber bellows worked by the patient himself; at foreign spas this work is done for everyone by a common force which is always acting. For sulphur waters this method is not available, as the jet of air speedily decomposes them. Here again, in the matter of these local inhalers, we see how abroad they make things as easy as possible for the patient. It may seem a small matter whether you blow your own bellows or not; and if the inhalation is to be for five or ten minutes only perhaps it is not of great importance. Yet we must remember that our inhalers are invalids to whom every exertion, mental or physical, is something of an annoyance.[3] But it is just these prescriptions of five and ten minutes which seem to me to be a mere playing with this form of medication, a species of quackery. What can you expect from a medicament which only acts for $\frac{1}{50}$th of the day. The inhalation bathes an excreting, not an absorbing surface, so that we cannot suppose that its action can continue for long after the inhalation has stopped. Cells so essentially scavenger-like as are the ciliated cells of the bronchi can scarcely be expected to pass on the medicament to the deeper tissues with any great energy. When I prescribe an inhalation I always try to get the patient to inhale for three hours daily, and if I fail to get a promise of one hour at least I drop it altogether for some other method of treatment. During inhalation respiration is deeper than with ordinary breathing. It should, therefore, always be done in pure air. I always endeavour that it shall be used out of doors. There are occasions when inhalation is used as a palliative only —e.g., as a sedative to cough before going to bed. Here, manifestly, if you achieve palliation it matters not how short a time the treatment has lasted. But when more far-reaching curative effects are desired then the longer periods are necessary.

I do not suppose any one of us questions the efficacy of treatment by inhalation when we have to do with nose, pharynx, larynx, or main bronchi, but many are sceptical as to its influence on diseased conditions of the alveoli or fine bronchioles. I think this scepticism is largely the result of our want of thoroughness in carrying out the treatment. When I have succeeded in getting it done for three hours daily for two or three weeks the improvement is usually so marked that there is no difficulty in persuading the patient to continue for two or three months. If the inhalation be a gaseous one—e.g., H_2S—I do not see how we can avoid the conclusion that diffusion will carry it right into the alveoli and that it will be there taken up into the blood along with the oxygen. But when the inhalation consists of an atomised liquid I admit the result is more doubtful. It will largely depend upon the fineness of the atomisation and upon the weight and volatility of the drugs used. In any case a large proportion must necessarily be deposited in the upper air passages. It would be unwise to use drugs which are not largely volatile at the temperature of the lungs; hence we find the volatile oils are favourite drugs for inhalation—e.g., the terpenes, eucalyptus, balsams of Peru and tolu, oil of cade, and betul. But we must remember that the tidal air is only one-thirteenth of the total air in the lungs; one half of this comes back again more or less unchanged; hence the inhalation when it reaches the alveoli can only be one twenty-fifth as strong as when it enters the mouth. When we consider the amount which has been deposited on the way we shall probably be right in saying that the percentage of active medicament which enters the alveoli cannot be more than one-fiftieth of that which enters the mouth. I am not saying this to discourage inhalation, for I believe it has a future; but there is no surer way of damning a therapeutic method than by expecting from it more than it can possibly give. On the other hand, when we call to mind the immense difference a comparatively minute change in the ordinary air makes in our health we cannot help believing that inhalation, properly employed, is a powerful therapeutic measure. But its power resides not in the percentage strength of the inhalation but in the vast quantity of it inhaled; that is, in the long duration of its employment.[4]

A STATISTICAL STUDY ON THE POLYMASTIA OF THE JAPANESE.

By Dr. TEIZO IWAI,

PHYSICIAN-IN-CHIEF OF THE JAPAN RED CROSS HOSPITAL; ATTACHED TO THE SUITE OF H I H. PRINCE FUSHIMI REPRESENTING HIS MAJESTY THE EMPEROR OF JAPAN.

ALTHOUGH there is mention in the seventeenth and eighteenth centuries of a few scholars in Europe having made a study of polymastia it was not until the latter part of the nineteenth century that the subject began to be handled in a scientific manner, and only in the last 15 years can we say that it has made marked progress. Realising that the subject has a close relation not only to practical medical science but also to anthropology, comparative anatomy, and embryology, and that its study has been neglected hitherto by our own investigators, I venture to months' work at the Barnardo institutions and Her Majesty's Hospital, Stepney, met with a case of arthritis apparently following purulent conjunctivitis even in debilitated subjects.

---

[3] I have tried, with the assistance of Messrs. Philip Harris and Co. of this city, to devise some plan for obtaining this constant pressure on a small portable scale suitable for one person. The city water pressure was evidently altogether insufficient for the purpose, and we found it practically very difficult to obtain sufficient pressure by placing weights on the open end of a cylinder which communicated with the fine nozzle. Either the cylinder was so small that its contents were speedily exhausted or else the requisite weight was so great as to be very cumbersome and impossible to be manipulated by the patient. A motor of some sort—a steam engine is used abroad—seems to be the only solution. Still, I trust it is not too Utopian to hope that such an apparatus may be placed in each large town where patients could resort, each taking his own nozzle and medicament, to be attached to the central power installation for a small fee per séance.

[4] The amount of air inhaled daily by an average man is no less than 10,000 litres. If we take the absolute amount of water vapour in the air we find that a considerable change in this, which acts as a diluent to the gases of the air, can make a considerable difference to the intake of oxygen—e.g., at Madras a man inhales 80·7 kilogrammes of oxygen a month; at London or Brussels 87·3; and at St. Petersburg as much as 90·4 kilogrammes—i.e., one eighth more oxygen at St. Petersburg than at Madras; or, [illegible], in a year he would inhale 270 pounds more oxygen at St. Petersburg than at Madras.

A CASE OF TRAUMATIC SUBCUTANEOUS RUPTURE OF THE SPLEEN; LAPAROTOMY; RECOVERY.

BY M. B. RAY, M.D., C.M. EDIN.,

SURGEON TO THE HARROGATE INFIRMARY.

THE patient, a boy, aged 19 years, was admitted under my care in the Harrogate Infirmary on Feb. 26th of this year. He was suffering from the effects of a kick in the abdomen by a horse. On admission he was in great pain, referred generally to the abdomen, and in a state of considerable collapse. He lay on his left side with his knees drawn up, any attempt to turn on his back causing intense distress. His face was pinched and somewhat cyanotic. The extremities were cold, the temperature was subnormal, and the pulse at first was 120 and feeble. The abdominal walls, especially on the left side, were very rigid, almost as hard as a board. The percussion note all down the left flank was quite dull.

The abdomen was opened in the middle line and the peritoneal cavity was at once seen to be full of fluid blood. As it seemed to come from the splenic region the incision was extended parallel to the left costal margin. The spleen was felt to be normal in size, but a ragged edge could be distinctly made out below the notch from which the hæmorrhage evidently proceeded. The amount of damage to the organ did not seem to call for extirpation, especially as firm pressure evidently controlled the bleeding. I therefore decided to tamponade. In this process I used about two and a half yards of sterile gauze. The median wound was then sutured and the patient sent back to bed.

The boy had a narrow, rickety chest and for some weeks previous to his accident had been troubled with a cough, accompanied by copious muco-purulent expectoration. This for the first few days got much worse and he had in addition some dulness about his left base. The latter, however, gradually cleared up. The packing was daily withdrawn little by little, commencing on the fourth day. The end of the gauze had caked into a hard mass and the wound had to be slightly opened under gas to allow of its removal. The whole of the tampon was finally removed by the end of the first week. A fistulous track, gradually becoming shorter, persisted for another fortnight. At the end of a month he was sitting up, taking food well, and putting on flesh. He was finally discharged cured on April 13th, six weeks after admission.

The case is interesting as demonstrating the importance of an exploratory operation in doubtful cases of abdominal injury. Also the number of successful cases of tamponading for rupture of the spleen is not great. At any rate, the number recorded is not.

Harrogate.

A CASE OF TWISTED OVARIAN PEDICLE IN A CHILD AGED THREE YEARS.

BY W. GREENWOOD SUTCLIFFE, *F.R C.S. ENG.*,

SURGEON TO THE ROYAL SEA-BATHING HOSPITAL AND VICTORIA CHILDREN'S HOME, MARGATE.

THIS case was first seen with my friend Dr. A. Warwick Brown at 10 P M. on July 17th. The patient was a healthy-looking child, just over three years old, who had been attacked by violent abdominal pains and vomiting 24 hours previously. A large rounded tumour was felt in the middle of the abdomen and operation was at once decided on. Chloroform was given by Dr. F. E. Nichol and Dr. Warwick Brown kindly assisted. On the abdomen being opened the tumour was, *to our surprise*, obviously ovarian; it was tapped but very little fluid escaped, and after enlarging the wound it was removed and the pedicle was examined. This was twisted four times and sprang from the right broad ligament. It was ligatured in the usual way and the wound, through the right rectus *sheath*, was closed. The small patient made an excellent recovery and is now running about as usual. The tumour was an ordinary adenoma, weighing 18 ounces, and of about the size of an average cocoanut; it was distended with blood clot and its pedicle was swollen as to measure some 4 inches in circumference.

Ovarian tumours are, of course, met with at any age, b torsion of the pedicle at the age of three years is, I thin sufficiently rare to record.

Margate.

HOSPITAL FOR SICK CHILDREN, GREA ORMOND-STREET.

A CASE OF CATARRHAL APPENDICITIS DUE TO THE PRESENCE OF THE OXYURIS VERMICULARIS.

(Under the care of Dr. A. E GARROD and Mr. H. A. T. FAIRBANK.)

A BOY, aged 10½ years, was admitted to the Hospital fo Sick Children, Great Ormond-street, on Dec. 22nd, 190 under the care of Dr. Garrod for incontinence of urine an *(?) epilepsy. The notes state that he complained of pain i* the stomach directly he began to eat, but no history coul be obtained of any attack suggesting appendicitis. O Jan. 5th, 1907, in the evening he complained of headach and he vomited. His temperature rose from normal t 101·6° F. The next morning he complained of pain in th abdomen and down the right leg. He vomited again, hi temperature again rising above 101°. An enema produced large constipated result. The next *morning his temperatur* was 103 2° and his pulse was 108. The abdomen was no unduly full and was not rigid, but there *was extreme* tenderness in the right lumbar region in front and in the loi behind, particularly in the latter *position*. There was n tumour to be felt. The right *thigh was fully extended* There was a leucocytosis of 26,000. By rectal examination nothing abnormal was made out. A diagnosis o appendicitis, with the appendix *lying* up behind the colon was made, and the boy was transferred to a surgical war and operated upon immediately.

The abdomen *was opened some*what higher than usual by McBurney's method. The appendix was found behind the colon in an unusually deep subcæcal pouch. It was quite free from adhesions and there was *no sign* of recent peritonitis. The vessels of the cæcum and appendix appeared a trifle larger *than normal and the terminal* portion of the latter was somewhat rigid, so its removal was proceeded with. The right kidney and ureter were normal. On slitting *up the appendix* after removal the mucous membrane was seen to be congested and in the lumen were found *some soft* fæcal matter and several thread *worms. The next day* the boy was much better and in 36 hours the temperature was normal. On the third day after the operation *the temperature again rose, reaching* 103·8° on the fourth day. The child had an attack similar to the former, *though* the local tenderness was not quite so marked and he *did not* vomit. The attack lasted three days and was followed by uninterrupted recovery, the wound healing by first intention. On the supposition that the cæcum *was probably* the seat of many more worms drugs were *given* with a view to their removal, yet not a single oxyuris could be *found* in the *motions* at any time. He left the hospital on Jan. 26th apparently quite well.

CHOLERA RISKS AT MOSCOW: PROVISION FOR MEDICAL MEN'S FAMILIES IN CASE OF DEATH.—In view of the threatened invasion of *cholera* the Moscow Hospital medical men have held a meeting at which it was decided, *inter alia*, that in the event of deaths amongst the members of the staff *compensation* (except in cases where pensions are provided) shall be paid to the *families* of such deceased at rates *varying* from *£100 in* the case *of* the lowest services *on* the staff to £500 in the *case of* the medical staff.

Dr. Kashida's observation, though he does not give the exact figures, they were found in most cases below the normal breasts. But when I compare the results of these two observers, Dr. Watanabe and Dr. Kashida, with the results of my own observations on several cases I am rather inclined to wonder at the former. According to Dr. Leichtenstern's observation 91 per cent. of these glands are found on the pectoral region, and most of them (94 per cent.) are below the normal breasts; and when they are as rarely found above (3 per cent.) the position is invariably outside of the normal breasts towards the axillæ. Dr. Hennig described the location of theso glands in the pectoral region as follows:—

Below the normal breasts	103
Above the normal breasts	3
Outer side of, and at the same height as, the normal breasts	3
Inner side of and lower than the normal breasts ...	37
Directly under the normal breasts	9
On the middle-line below the pair of normal breasts ...	5
Outer side of and lower than the normal breasts ...	1

Dr. Testut, taking 100 cases mentioned in the record made by Dr. Leichtenstern and Dr. Laloy, classified the position of these glands in the pectoral region as follows:—

Below the normal breasts	93
Same height as the normal breasts	2
Above the normal breasts	4
Both above and below the normal breasts	1

Dr. Bonnet says that in most cases the glands are found in the pectoral region below the normal breasts and chiefly on the inner side of them. Sometimes, but rarely, they are found above and outward of the normal breasts, or near the axillæ, or even in the axillæ themselves.

Apart from the question whether they are above or below the normal breasts, I have observed that the number of those on the left is greater than those on the right. Out of 936 of these glands I have seen 481, or 51·38 per cent., on the left, and 454, or 48·50 per cent., on the right, and only one, or 0·10 per cent., on the median line. Upon this point both Japanese and European authorities seem to agree, as will be seen from the following statements. Dr. Wiedersheim says that whenever supernumerary glands are more numerous on one side they are generally on the left side. Dr. Leichtenstern writes that out of 50 cases 34 had them on the left and 16 on the right. Dr. Ammon mentions 85 cases on the left and 32 on the right that have come under his observation. Dr. Watanabe, alone differing from all the above mentioned, states that out of 134 supernumerary glands which he had seen 64 were on the left and 70 on the right.

Supernumerary glands on the midway line are very rare. Dr. Gorré and Dr. Percy mention a case of a woman and Dr. Bartels of a man. I once saw a male tuberculous patient, 36 years of age, who had such a gland on the linea alba nine centimetres below the point of the xiphoid appendix of the sternum and 15 centimetres below and inward of both normal breasts. Although Western authorities mention cases in which these glands are found on the shoulder, back, thigh, labia majora, &c., I have not been able to find them anywhere but on the chest and abdomen. Dr. Leichtenstern classifies 105 cases of polymastia with regard to the position as follows:—

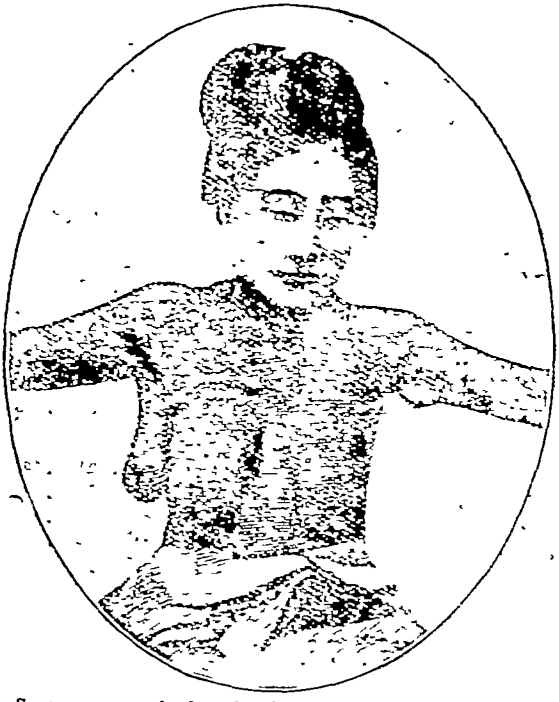
Pectoral region	96
Axilla	5
Back...	2
Shoulder...	1
Outer side of thigh	1

Dr. Hennig gave the following table:—

Pectoral region	105
Axilla	9
Shoulder...	1
Back...	5
Inguinal region	3
Outer side of thigh	3
Labia majora...	1
Ovary	1

Dr. Baelz has told me of a European gentleman who had a well-developed accessory mammilla on the inner side of the left thigh and another on the pectoral region near the left axilla. Dr. K. Satō, in his second report, writes of having observed a woman, 23 years of age, who had given birth to three children and had distinct mammary glands in both axillæ and under the skin of the left upper arm, which during the pregnancy were swollen like normal breasts. As the existence of the glands on the upper arm is exceedingly rare, and as far as I know has not been found in medical literature, I have here reproduced the photograph of the same with his permission.

FIG. 2.



Supernumerary glands under the skin of the left upper arm and the right axilla, taken from Dr. K. Satō's second report.

The following is a table compiled as the result of my examination of 936 cases of polymastia.

Total number of polymastiæ 936.	Male	250	Above normal breasts	190	Left ...	92
					Right...	98
			Below normal breasts	60	Left ...	37
					Midway	1
					Right...	22
	Female	686	Above normal breasts	662	Left ...	338
					Right...	324
			Below normal breasts	24	Left ...	14
					Right...	10

The following is a table compiled from Dr. Otani's reports made at two different times:—

Total number of supernumerary glands 610	Male	197	Above normal breasts	152	Left ...	86
					Right...	66
			Below normal breasts	45	Left ...	30
					Right...	15
	Female	413	Above normal breasts	388	Left ...	201
					Right...	187
			Below normal breasts	25	Left ...	12
					Right...	13

Again, the results of Dr. Watanabe's observation upon the conscripts are as follows:—

Total number of supernumerary glands	134	Above normal breasts	7	Left ...	2
				Right...	5
		Below normal breasts	127	Left ...	62
				Right...	65

By putting the above three tables together we obtain the following result:—

Total number of supernumerary glands 1650.	Male	551	Above normal breasts	349	Left ...	180
					Right...	169
			Below normal breasts	232	Left ...	129
					Midway	1
					Right...	102
	Female	1099	Above normal breasts	1050	Left ...	539
					Right...	511
			Below normal breasts	49	Left ...	26
					Right...	23

instance and to extirpate it in others, and when it is proper to deal with the sympathising or uninjured one. We notice that little is here said of any distinction between sympathetic irritation and sympathetic inflammation, yet antiseptics and rest in a darkened chamber with some general treatment will sometimes altogether remove the one and have little or no beneficial influence on the other. The treatment proposed for penetrating wounds in the ciliary region (p. 437) though correct for an expert with all appliances at hand seems too difficult for the junior practitioner. It would not be advisable, we think, for an unpractised hand in a case of a cut with a penknife, a very common form of injury, to insert fine silk sutures into the sclerotic but which are not to be tied, "great care being exercised not to press unduly on the eye. The prolapsed iris and ciliary body are then excised as in the operation for simple prolapsed iris. The scleral sutures are then tied. Finally the conjunctiva is sutured over the wound." The student or general practitioner would, we think, be better advised to send such cases to some large centre where the operation could be undertaken by one who is familiar with the operative surgery of the eye, or, failing this, to wait a week or two, and if the appearances were threatening and no improvement took place to remove the eye; as a rule, a delay of a fortnight does no harm.

We have left ourselves no space to comment upon the sections devoted to the neurology of vision and upon the disorders of the motility of the eye. These, no less than the others, are thoroughly worked up to date, and the book as a whole may be regarded as a very sure guide to the student and as representing the practice of one of the best schools of ophthalmology in Europe.

Le Sol et l'Eau. (*Soil and Water.*) Par L. DE LAUNAY, Professeur à l'École des Mines; E. A. MARTEL, Auditeur au Comité Consultatif d'Hygiène; ED. BONJEAN, Chef du Laboratoire du Comité Consultatif d'Hygiène de France; et J. OGIER, Chef du Laboratoire de Toxicologie de la Faculté de Médecine de Paris. With two coloured plates and 80 figures in the text. Paris: J. B. Baillière et Fils. 1906. Pp. 460. Price Fr.10.

THIS book, which constitutes the second fasciculus of a treatise on hygiene published under the editorship of Professor P. Brouardel and M. E. Mosny, deals in a most exhaustive and interesting manner with the examination of the characters of the soil in regard to the problems of human habitation and with the general properties of water from a hygienic point of view. It commences with a geological study of the soil by M. L. de Launay in which the general characters of soil and sub-soil are described. Geological maps and sections are illustrated and their uses indicated. The constitution of the soil and the penetration of water through it are described.

M. Bonjean contributes a chemical and bacteriological study of the soil and discusses the rôle of the soil in regard to human habitation. He gives in detail the chemical composition of the different varieties of earth, and describes their physical properties. The relations of bacteria to the soil are given in detail, the problem of nitrification is discussed and the general distribution of pathogenic and other organisms, with their vitality in the soil, are described. The mortality rates of dwellers upon different kinds of soil and the nature of the so-called telluric affections concludes this section.

The geological relations of water are contributed by M. E. A. Martel. In this section the origin and nature of subterranean waters are described in detail and these waters are classified. The essential characters of potable waters are laid down and the various sources of pollution are considered, with the means to be adopted for counteracting them. The various possible sources of water—viz., rain, small springs, wells, rivers, lakes, and the sea are each separately dealt with, and the legal procedures necessary for the effective control of the supply of drinking water are summarised.

The remaining section of the book is contributed by M. Ogier and M. Bonjean and deals with the examination of water from the microbiological and chemical points of view. It occupies more than half the total pages of the book and is one of the most thorough and complete studies of the subject with which we are acquainted. The various characters of potable waters are given very carefully and the methods of water examination are described in detail, with especial descriptions of the methods used in the laboratory of the French Committee of Hygiene. The various bacteria found in water are separately considered and their morphological and cultural characters presented very clearly. The ordinary intestinal parasites and their ova and other small animal organisms sometimes found in water are described and figured. The various methods for the chemical analysis of water are next given and the significance and value of the results obtained are discussed. A very considerable amount of attention is given to the methods of purifying and improving the water-supply, and in this connexion the methods for filtration on a large scale are referred to and discussed, the special forms of filter like the Pasteur-Chamberland and the Berkefeld are figured and the methods of purification by chemical processes are also dealt with. An interesting account is given of certain methods for the sterilisation of water by means of ozone generated by electrical apparatus.

The book as a whole is a very valuable contribution to the works of reference on the subject of hygiene and is worthy of the reputation of the editors.

Hay Fever, Hay Asthma: Its Causes, Diagnosis, and Treatment. By WILLIAM LLOYD, F.R.C.S. Edin., Surgeon-in-Charge of the Nose, Ear, and Throat Department, Queen's Jubilee Hospital; Surgeon to the Nose and Throat Department, St. Pancras and Northern Dispensary. London: Henry J. Glaisher. 1907. Pp. 95. Price 3*s.* 6*d.*

THE author explains in his preface that his chief reason for writing this book was to record certain opinions which he holds upon the causes and effective treatment of hay fever. He admits that these opinions are not exactly in accordance with those generally current in this country but is convinced, he says, from a considerable experience that they are substantially correct. He divides cases of hay fever into two distinct clinical types, dependent upon the predisposing pathological cause. In the first type, on examination of the nose no structural abnormality is discovered, but certain areas of the mucous membrane are hypersensitive. In the second, some pathological condition or abnormality is present, together with hypersensitive areas. Amongst the intranasal diseases present he mentions simple chronic catarrhal or hypertrophic rhinitis, polypi, sinus diseases, ethmoiditis, adenoids, deflected septum, spines and crests, and foreign bodies, or rhinoliths. Mr. Lloyd considers that his first group forms the true type of hay fever, and the symptoms are only produced by the action of pollen; the second group, he suggests, should be termed pseudo hay fever; the symptoms are much the same, but may come on during any period of the year. We think, however, that it is not desirable to include the second group under the heading of hay fever but to designate them according to the morbid condition which exists. The main etiological factor is quite different, in the one the pollen is the prime cause of the disease, whilst in the other the pollen is of only secondary importance.

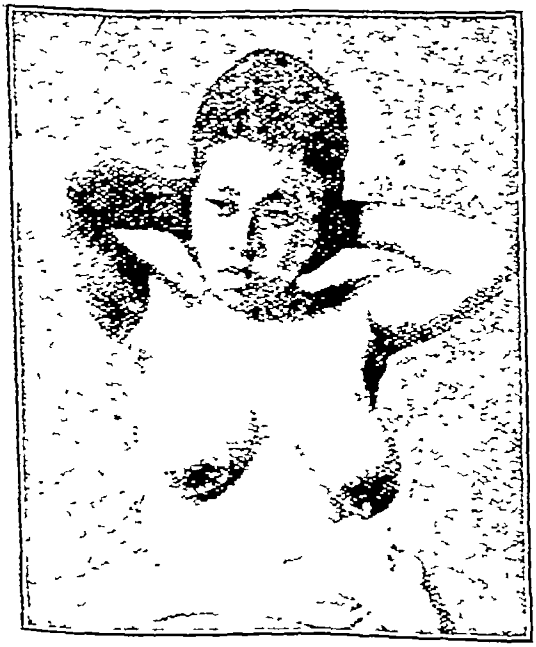
In regard to treatment Mr. Lloyd lays great stress on the importance of cauterising the hyperæsthetic areas. Obvious abnormalities such as adenoids and polypi must, of course, be removed, but this procedure, he says, will not always give the expected relief, and the electric cautery must then be applied to the areas just named. This method of treatment case of transmission from the father like that described by Dr. Péterquin. The case observed by Dr. Otani in Nagasaki, in which polymastia was inherited through four generations, from the great-grandmother to the grandmother, to the mother, and to her six children (three boys and three girls) is the most remarkable one on record.

MAMMARY GLANDS OF POLYMASTIA AND THEIR SECRETORY PROCESS

The development of polymastia is not always uniform. As Mr. J. Bland-Sutton has pointed out, there are three forms of its development: (1) the nipple, areola, and glands are so completely formed that they do not differ from the ordinary mammæ; (2) as we see very often, the nipple alone is existing—polythely; and (3) as in the cases reported by Dr. Satō and myself, the glands were found under the skin. In cases where these glands are fully developed there is generally more or less secretion of milk at the time of parturition; but the amount of milk and the duration of the secretory period are not always the same. I observed 11 cases in which the secretion was found at the time of parturition; and the longest period of lactation in my observation was six months after parturition. Although Dr. Uno, as above stated, mentions a case in which a woman was considerably annoyed after parturition by having dripping of milk from supernumerary glands in both axillæ, all my experience has proved to me that the secretion is obtained only by pressing or squeezing, and in so doing I could first obtain an uncoloured thin liquid, followed by cream-coloured milk.

The microscopical examination of the milk drawn from the glands a few days or a few months after parturition very often proves the existence of a great number of milk globules and a few epithelial cells. Whether there are glands or not in the polymastia cannot be ascertained until the subject has given birth to children several times. Although at ordinary times there may not seem to be any glands, when the lactation period comes on there are many cases where perfect secretion is performed. In the case cited by Dr. K. Satō the supernumerary glands at the anterior edge of the right axilla had a swelling of the size of a pigeon's egg which at the time of parturition, together with the ordinary mammæ, became enlarged to the size of an orange At her second parturition a swelling of the same size appeared at the same place on the left and also on the inner side of the upper arm. At this time the one on the right had swollen to a lump larger than the fist. At the third parturition it became enlarged to such an extent as to prevent the movement of the right upper extremity, so that Dr. Satō was obliged to remove it by a surgical operation. (See Fig. 2.) Later, at the fourth parturition, a regeneration of the mammary gland had appeared again at the same place on the right and gradually swollen to a lump as large as the fist. At the fifth parturition he was again obliged to remove it.

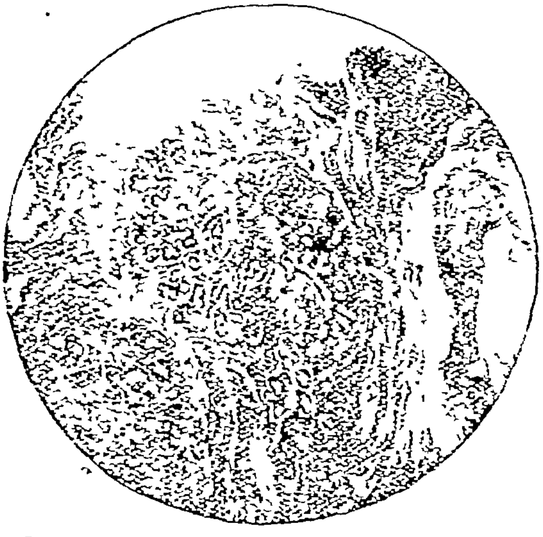
FIG 3



Supernumerary mammary glands in both axillæ secreting milk.

During the year 1906 I myself, too, observed in a woman who had given birth to triplets a bunch of the size of an egg which had appeared under the skin of the left axilla and atrophied within 30 days after the parturition. In July, 1903, Dr. Kinoshita, Professor in the Tokyo Imperial University, had kindly invited me to examine a female patient at the hospital of the Tokyo Imperial University, where I had an opportunity of observing a very interesting case of polymastia. The said patient, who was 24 years of age, was then on the eighth day after her third confinement. At the examination I found in her a supernumerary mammary gland of the size of a pigeon's egg in each axilla and a smaller one on each anterior wall of both axillæ. (See Fig. 3.) After squeezing them I recognised the secretion of milk from each of them.

FIG. 4.



Section of a supernumerary mammary gland in a case of polymastia.

In the case observed by Dr. Neugebauer, that of a woman 23 years of age having supernumerary mammary glands eight in number, at the first parturition no change took place, but from the second day of the second parturition the process of secretion commenced in every one of them. Through the kindness of Dr. Satō I was enabled to examine the glands which he had removed, and by examination of the microscopic specimen of the same I have been able to ascertain the existence of acinous glands in it. During the month of April, 1903, I had, however, an occasion of taking a supernumerary gland out of a woman 27 years of age. The microscopical examination of this proved the existence of acinous glands. (See Fig. 4.)

CONCLUSION.

From the above statements I have arrived at the following conclusions:—

1. Among the Japanese, unlike the Western people, polymastia is generally found above the normal breasts, and most commonly on the anterior wall of the axilla, or the region II. indicated by Dr. Williams

2 It is likely that in many cases of polymastia the areolæ of those under the normal breasts are pigmented, and that in males they are more likely to be pigmented than they are in females.

3 According to the result of investigations made by myself and others up to the present time the rate of polymastia is 1·68 per cent. among males and 5·19 per cent. among females. The fact that we find it more frequently in females than in males, and on the left side than on the right. exactly coincides with the results obtained in the West.

study of these two volumes. The new illustrations attain an even higher standard of merit than those in the first edition, and this is saying a great deal.

LIBRARY TABLE.

Outlines of the Diseases of Women. By JOHN PHILLIPS, M.A., M.D. Cantab., F.R.C.P. Lond., Professor of Obstetric Medicine and Diseases of Women, King's College Hospital. With 121 Illustrations and two appendices. Fourth edition, revised and enlarged. London: Charles Griffin and Co. 1906 Pp. 282. Price 7*s.* 6*d.*—As this book, of which Dr. Phillips has issued a fourth edition, is only an outline of the diseases of women we must not, of course, expect too much in the way of detail. The author has revised the new edition and more particularly those portions of the book dealing with chorion-epithelioma and the operation of ventro-suspension of the uterus. It is disappointing to find that the process of revision has not been carried out as thoroughly as it might have been; for instance, in considering the operative treatment of inversion of the uterus we are told that, if failure in the attempt at reposition has taken place and hæmorrhage is severe, amputation by the elastic ligature or electric cautery is advisable. We think that even the most conservative gynæcologist would not carry out such entirely obsolete treatment when the removal of the uterus by the easy operation of vaginal hysterectomy is undoubtedly the correct treatment, granting that other operative procedures, which by the way are not even alluded to, are unsuccessful. We fail also to see that division of the pedicle of a fibroid polypus with a wire écraseur is a better plan than the cutting through of the pedicle with a pair of scissors such as is the usual method of treating such cases. Dr. Phillips still recommends Apostoli's treatment carried out by the intrauterine method. In the same section on the operative treatment of fibroid tumours of the uterus we are told that oöphorectomy is indicated in young women with slowly growing hæmorrhagic fibroids. We should have thought that removal of the ovaries was contra-indicated especially in the case of young women. In the treatment of cancer of the cervix a considerable amount of space is devoted to supravaginal amputation of the cervix, although nothing is said of total abdominal hysterectomy, which seems curious. The author is of opinion that some cases of chorion-epithelioma may in reality be cases of decidual sarcoma. It is a pity that the drawing on p. 229 illustrating the characteristic contents of ovarian cystomata has not been deleted as its retention might lead the student to believe that the microscopical appearances are characteristic, whereas as a matter of fact they are not so at all.

The Operations of General Practice. By EDRED M. CORNER, M.A., M.C., M.B. Cantab., B.Sc. Lond., F.R.C.S. Eng., Surgeon in Charge of Out-patients at St. Thomas's Hospital and to the Children's Hospital, Great Ormond-street; Consulting Surgeon to the Wood Green and Purley Hospitals; formerly Erasmus Wilson Lecturer to the Royal College of Surgeons of England; and H. IRVING PINCHES, M.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Clinical Assistant to the Children's Hospital, Great Ormond-street; late House Surgeon and Obstetric House Physician to St. Thomas's Hospital. London: Henry Frowde and Hodder and Stoughton. 1907. Pp. 296. Price 15*s.* net.—This is one of the Oxford Medical Publications, a useful series of books only recently commenced. There can be no doubt that at the present time there is a very great tendency for those medical men who are in general practice to operate more frequently than 20 or 30 years ago, but there has been a want of a suitable work giving clear instructions for the operations which a general practitioner would be inclined to undertake. This want appears to us to be very well supplied by this book. It is large without being too big; it is clearly written, and gives just that amount of assistance which is likely to be needed. There is an introduction with a general discussion of surgical matters, such as asepsis; then follows a chapter on anæsthetics, and after that come chapters on the operations on different parts of the body. The illustrations are adequate.

A Dictionary of Medical Diagnosis: a Treatise on the Signs and Symptoms observed in Diseased Conditions, for the Use of Medical Practitioners and Students. By HENRY LAWRENCE MCKISACK, M.D. R.U.I., M.R.C.P. Lond., Physician to the Royal Victoria Hospital, Belfast. London: Baillière, Tindall, and Cox. 1907. Pp. 583. Price 10*s.* 6*d.*—It is only by attendance in the wards and out-patient rooms that the student can obtain the requisite experience to enable him to recognise and correctly to interpret the phenomena met with in disease, but a written guide to which he can turn for help will be valuable to him. In order to meet this requirement Dr. McKisack has written the volume under consideration, and we believe that students will find it useful to them in their clinical work and that practitioners will also be able to consult it with advantage in order to refresh their memory as to the significance of physical signs and symptoms when dealing with obscure or complicated cases. In order to facilitate reference to the different subjects these are arranged in alphabetical order and not in anatomical or nosological grouping; as the work is intended as a complement to, and not as a substitute for, the recognised text-books on medicine this is a good procedure. We have been well satisfied with our perusal of the work. It is complete and explicit, and an explanation of much of the more modern terms employed in medical literature will be found in it. In order to assist the reader in the study of differential diagnosis comparative tables are frequently employed; these are valuable not only for instruction but also for facility of reference. The book is well illustrated, containing numerous diagrams and reproductions of photographs illustrative of the text.

The Ophthalmoscope: A Manual for Students. By GUSTAVUS HARTRIDGE, F.R.C.S. Eng., Surgeon to the Royal Westminster Ophthalmic Hospital, Ophthalmic Surgeon to the Westminster Hospital, &c. Fifth edition. With 68 illustrations and four plates. London: J. and A. Churchill. 1907. Pp. 153. Price 4*s.* net.—This little book, while not so successful as its companion volume by the same author on the refraction of the eye, has yet attained a large measure of success. The book in reality is an incomplete student's manual on the diseases of the eye and the methods of their investigation by means of the ophthalmoscope. There seems to be a demand for small and concise books of this description, presumably amongst examinees, though this particular specimen has none of the demerits of a cram book. The material, though necessarily incomplete, is thoroughly trustworthy and clearly expressed. The plates in monochrome of diseased conditions of the fundus are not very satisfactory and might advantageously be replaced by coloured representations in a future edition

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc D., F.R.S. Vol XXXVI., No. 1. August 27th, 1907. London: C. F. Clay. Price 5*s.*—The articles contained in this number are: 1. The Non-existence of Protagon as a Definite Chemical Compound, by Otto Rosenheim, Ph.D., and M. Christine Tebb. The authors show that Liebreich's, Gamgee and Blankenhorn's, and Cramer's protagons represent practically the same substance as cérébrote prepared by Couerbe in 1834. By fractional crystallisation substances can be obtained from protagon which differ much *inter se.* Thus protagon with about 1 per cent of phosphorus yields when appropriately treated phrenosin containing no phosphorus and sphingomyelin which is rich in phosphorus.

SPONTANEOUS ANEURYSM OF THE POPLITEAL ARTERY TREATED BY EXTIRPATION.

By H. A. LEDIARD, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO THE CUMBERLAND INFIRMARY.

MUCH that has been written upon aneurysms of the limbs, and especially those of the popliteal artery, requires to be revised, in the light of modern methods of dealing with this disease, whether of spontaneous or of traumatic origin. For example, in Vol. LXXXII. of the Transactions of the Royal Medical and Chirurgical Society a paper on extirpation of a large non-pulsating aneurysm of the carotid artery, by the late W. J. Walsham, will be found, together with a very useful table of cases of various aneurysms treated by extirpation. Carotid, femoral, subclavian, inguinal, and tibial aneurysms are tabulated as well as popliteal, but for the present purpose allusion will be made to the 17 popliteal aneurysms only, forming as they do an excellent group for demonstrating the value of treating aneurysms of this artery by extirpation. Of this group, 13 were spontaneous aneurysms and were dealt with by exposure of the sac, ligature of the artery on its proximal and distal sides, and removal of the sac. All these cases came from foreign sources; 11 recovered and two died. The case now placed alongside with this group was treated in the same way.

A man, aged 54 years, a labourer in gas works, came under observation on August 25th, 1905, suffering from a popliteal aneurysm on the right side. Three months previously he strained his right knee and afterwards had always felt pain in the knee and down the calf of the leg when at work. A fortnight before admission to hospital he noticed a swelling behind the knee of about the size of a pigeon's egg; this swelling grew rapidly in size before he came for treatment. Behind the right knee there was a large pulsating fusiform swelling, expansile in all directions; a thrill could be felt over it and with a stethoscope a murmur could be heard. Pulsation and swelling could be obliterated by pressure on the femoral artery.

On August 28th chloroform was given, a tourniquet was applied to the thigh, and the patient was turned on to his face. An incision six inches long was made over the popliteal space; the politeal artery was dissected out above the aneurysm, ligatured in two places, and cut between the ligatures. The artery was cleared below the aneurysm and the same method adopted as above; the aneurysm was then dissected away. The only difficulty met with was due to adhesion of the popliteal vein to the sac of the aneurysm. More than five minutes were lost in the endeavour to separate the union, but this was found impossible and the vein was divided. From the sac an artery of some size passed forwards to the knee-joint. When the sac was just upon cleared it broke off from the distal ligature, showing the degenerated and brittle condition of the vessel. The sac was not opened until the operation was over, and was got away with comparative ease and without damaging its walls. Within the aneurysm there was little or no clot, or any found there was in decolourised flakes of fibrin adhering to the wall. The wall of the sac was as thin as brown paper and the size of the sac was equal to the fist of an infant three months old or to a russet apple. On August 30th the patient complained of cramp in the calf of the leg and a hot burning feeling across the instep and sole of the foot. Circulation in the toes was good. On Sept. 7th the burning feeling and numbness were gone; the stitches were removed. On Nov. 25th a sinus which had persisted was touched with pure carbolic acid. On Dec. 12th the wound had healed. The patient was able to kneel slowly without pain and walk with only a very slight limp.

With regard to the later progress of the case I heard from the patient on April 11th, 1907, when he reported himself as able to walk three or four miles without trouble or without a stick and he was engaged as a gardener and to do light work about a house. He stated that he had not the strength in his leg for any heavy work.

The method of treatment adopted was that which was considered by Walsham to be the ideal way of extirpating an aneurysm, for the whole aneurysm was got rid of and the cure was radical. The only damage done to other structures was due to the adhesion of the popliteal vein to the sac: a possibility to which Walsham drew attention; but it does not seem that cutting the vein is likely to be attended with any evil consequences. Perhaps the reason why reluctance has been shown to performing excision of a popliteal aneurysm is that it was formerly taught that cutting the popliteal vein would assuredly be followed by gangrene of the limb, but here it was the anatomist who spoke and not the surgeon. So often has this important adhesion been found that the surgeon who extirpates a popliteal aneurysm will always be on the outlook for it. In other respects, a popliteal aneurysm will not be likely to have contracted any adhesions. Even in Walsham's case of non-pulsating carotid aneurysm he speaks of it as well encapsuled, though slightly adherent to the neighbouring parts.[1] In short, for a case of uncomplicated spontaneous aneurysm of the popliteal artery excision of the sac will prove a comparatively simple operation. The ages of the cases given in Walsham's table ranged from eight to 63 years, and it is interesting to note that the man aged 63 years did quite well. One death was due to suppuration of the knee and the other to gangrene.

The risks associated with extirpation of popliteal aneurysm are possibly the same as those connected with other methods of treatment. Gangrene of the limb has followed compression of the femoral artery as well as after ligature and will perhaps occur in cases of extirpation. Compression has been stated in the record of cases of popliteal aneurysm to have cured in hours, days, weeks, and months, up to six, from which it may be gathered that considerable uncertainty attends this plan of treatment. Far more certain results have followed ligature of the femoral artery, but failure to cure by this method is also on record. Not only in popliteal aneurysm has ligature failed to cure, but in Henry Morris's case[2] a return of pulsation occurred in a carotid aneurysm after ligature of the carotid, and the old operation of laying open the sac, turning out the clots, and tying the vessels was done, but the sac was not removed.

Given an aneurysm cured by compression or ligature of the femoral so that the sac ceases to pulsate and the clot, if present, contracts, who can say if the cure will be a permanent one, or if trouble will not arise in the future, as in Scott's case,[3] exhibited on April 27th, 1894? A popliteal aneurysm had been treated by compression, flexion of the limb, and finally by ligature of the artery, and was apparently cured. Three years later the tumour began to increase in size and subsequently gangrene of the foot set in. The aneurysm was dissected out and a Chopart's amputation was performed. Primary removal of the aneurysm would appear to have been a better plan of treatment.

I can well understand a false aneurysm giving far greater trouble to extirpate; the tissues have been distended with clot and disguised, the mouth of the wounded artery is not found at once, but it is just in such cases that extirpation of the aneurysm has been attempted and successfully carried out. For example, in THE LANCET of May 20th, 1893, p. 1214, is a note on a case taken from the *Revue de Chirurgie* treated by M. Terrier and M. Hartmann, where a diffuse popliteal aneurysm caused by an exostosis growing from the inner supracondyloid ridge was dealt with by excision of the injured portion of the artery and the patient recovered with full use of his limb.

In Walsham's table under another heading are three cases of popliteal aneurysm in which the sac was opened, clots were turned out, the artery was tied, and the sac was removed; all these recovered. Of popliteal aneurysms with false sacs Walsham gives a case by Littlewood, where a false sac was laid open, clots were turned out, the true sac was discovered, the artery was tied above and

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 14, 1907.

The Plague in India.

IT appears that the net result of the two years' consideration by the Government of India of the proposals of the Royal College of Physicians of London is to condemn the recommendation of the College that a special organisation for dealing with plague should be formed, but to admit that a general sanitary service requires development.[1] Further than this there is apparently no progress, for Mr. MORLEY was still awaiting information regarding proposals in this direction when he penned the dispatch on July 26th, calling attention to the importance and urgency of the question, expressing his anxiety to be placed in possession at the earliest date of the view of the Indian Government, and recording his regret that greater expedition could not have been found practicable. Possibly the Secretary of State for India had also in mind at the time of his dispatch the questions which Dr. H. V. RUTHERFORD had asked so long back as April last concerning the strength of the medical staff specially deputed for plague work in India, the answers to which he was still awaiting, although three days at most would have been ample time for collecting the information. Things must move slowly in India when it takes over three months to learn what is the actual establishment devoted specially and wholly to plague work. We suspect that some of the active and passive resistance to reforms which Lord KITCHENER experienced in his proposed reorganisation of the Indian army, and which he successfully overcame, has now been transferred to the equally urgent and necessary reforms in the sanitary organisation in India. The particular name or form of the proposed sanitary organisation is a matter of small moment provided the service so formed is the very best for combating plague in India, and that it is formed quickly. We hope, however, that it will be the outcome of proposals by medical officers of great and practical experience in plague and sanitary work and not a cut-and-dried scheme from the secretariat in India, the source of many different plague policies. We further trust that in any scheme of development of a sanitary service it will be recognised that in dealing with qualified Indian medical men and women trained in preventive medicine a corresponding status in the service must be given to them according to the responsibility placed on them. It is only by ungrudgingly treating the Indian sanitary service as a great and important branch in the Civil Service of the country that the best work will be obtained from it. The fewer sanitary inspectors there are probably the better. Sanitary inspectors are not usually a success in the East; monetary considerations are liable to destroy their utility. Doubtless the creation of a separate public health service in India will have a dislocating effect on the existing medical and sanitary administration of the country. Evidently the Royal College of Physicians foresaw this contingency, for no radical changes were recommended, but a scheme embodying a slow and progressive development towards the attainment of a separate and special department the sole duty of which in the first instance should be the prevention and mitigation of plague epidemics while this disease continued its ravages in India.

Let us turn to the recently published correspondence between the Government of India and the Secretary of State for India for information as to the views held by the former.[2] One of the main objections put forward by the Government of India to the organisation proposed by the Royal College of Physicians is its unsuitability to India, but the papers relating to the Punjab show that this province actually possesses on a very small scale an organisation not dissimilar from that which the Royal College of Physicians recommended. The province is stated to have a special plague staff consisting of ten medical men belonging to the Indian Medical Service, four physicians sent out from England, and a subordinate staff of 23 assistant surgeons and 36 hospital assistants. The difference between this and the scheme recommended by the Royal College of Physicians lies in the fact that in the latter qualified women are added, and the suggestion is made that there should be, to begin with, a similar organisation for at least four or five centres, that these centres should be used as training places for other medical men and women in order that other fresh centres could be formed where most needed, and that in this way a special plague organisation should be brought into being and developed. It is not likely to be contended seriously that 14 medical officers with a few native assistants can cope in the slightest degree effectually with such an epidemic as that which has been prevailing in the Punjab during the past seven years, even when there are added to this special organisation the 29 civil surgeons with their other duties. The Punjab is slightly larger than Great Britain. It is divided into five divisions, has 29 districts, and 140 small towns. It is only necessary to state these facts to make clear the absurdity of attempting to combat one of the worst epidemics known in history with 14 medical men and their assistants.

In the Madras Presidency, where plague has been kept under reasonable control, it is stated that the Royal College of Physicians' "scheme is for all practical purposes not materially different from that which is now in existence in this presidency," and we learn later that a sanitary organisation was begun in 1895—i.e., a year after a sanitary service was recommended to the Government of India by the Medical Congress held in Calcutta in 1894. A similar reply comes from the United Provinces of Oudh and Agra. So that in at least three provinces the principle of the proposed organisation has already been accepted and is in operation, which are facts that do not consort well with into one, scraped out, and laid open by flaps on Nov. 10th. On Dec. 4th the fever and discharge continued; the right rectus was cut across and was found to contain pus. Anti-streptococcus serum was now given, the disease being supposed to be due to cocci. On the 20th pneumonia was discovered at the right base, which advanced and spread later to the left base also. On Jan. 11th the patient died.

---

[1] See THE LANCET, August 24th, 1907, p. 537.

[2] Correspondence regarding *Measures for the Prevention of Plague.* Wyman and Sons, London. 5½d.

Necropsy.—The intestines were much matted and the right lower abdomen was full of massive adhesions inclosing loculi of pus. There was an abscess about the tip of the appendix, which was perforated and imbedded in adhesions. The liver contained an abscess of the size of a cricket ball. The pleuræ on both sides were adherent above and contained offensive pus below. The lungs were full of small abscesses. Sections of both lungs and liver showed actinomycosis. Though this had never been found in the discharge from the abdomen, there can be little doubt that the fungus was introduced through the abdomen, presumably by means of *the pin.*

CASE 2.—A female, aged 43 years. The patient was a widow and was admitted on Oct. 1st, 1902, complaining of pain in the right side of the abdomen. The pain had lasted seven days. Five days ago she was sick. Previously to this illness she had an attack of pain in the left side of the abdomen three years ago "cured" by medicine. On admission she looked healthy; there was no pain. The temperature was 100·6° F. and the pulse was 107. There was a hard, round, dull, tender swelling in the right iliac fossa, not involving the skin. The rest of the abdomen was soft and moving freely. For several days she seemed better and the temperature became normal, though the lump was unchanged. The temperature again reaching 100·5°, on Oct. 7th an abscess far back in the loin, containing half a pint of fœtid pus, was opened and drained through the usual appendix incision. There were massive adhesions. The appendix was not found. She rapidly improved, the wound closed, and she left apparently cured.

On Dec. 2nd the patient was readmitted with an abscess in the right loin above the old operation scar. This was opened and drained. The skin was thickened and brawny, bluish and shiny. On the 22nd and 30th two further abscesses in the right loin were opened. There were now hectic fever and wasting. On Jan. 8th, 1903, there was great induration of the whole of the right loin, where the original abscess about the colon had resolved itself into three foci, the third of which was now opened. Yellow granules were noticed in the pus which proved to be actinomycetes. On Feb. 24th the loin was still indurated and riddled with sinuses, and three fresh spots appeared above the iliac crest. The fever continued at 101° nightly. On March 17th and April 7th fresh abscesses were opened and scraped. On June 20th the base of the right lung was consolidated, the breath sounds and vocal fremitus being absent. The chest wall was bulging and the skin was red and œdematous. Three weeks later a sinus burst over the scapula. On Sept. 3rd seven ounces of pus were evacuated from the chest at the level of the fifth rib. Other abscesses formed and were dealt with in the chest on the right side. On Nov. 11th the patient was discharged. She died "some months later." There was no necropsy.

CASE 3.—A male, aged 14 years. He was admitted on Jan. 7th, 1906, complaining of pain in the abdomen. On Dec. 26th he had pain at the umbilicus, but did not vomit. The bowels had been open regularly since. The boy did not leave work until Jan. 6th, when the pain became worse and was localised in the right iliac fossa. There was no history of swallowing anything. He had had a little abdominal pain in the previous autumn. On admission he was pale and thin but was not looking ill. He walked in. The temperature was 100·2° F., the pulse was 120, and the respirations were 18. The tongue was clean. There was a hard, tender, rounded well-defined lump in the right iliac fossa of the size of a cocoanut; the rest of the abdomen was soft and moving freely. The skin was normal. A diagnosis of appendicitis abscess was made and immediate operation was performed. Immense densely matted adhesions were found. With great difficulty a way was made through these. The caput cæci was found in a mass of adhesions; the appendix was firmly imbedded in omentum and adherent to the transverse colon by its tip. It was ligatured and cut away, but invagination failed. Time one and a half hours. A tube was inserted. The appendix was constricted; beyond this it was thickened. Lying inside it, in a sloughy bit of mucous membrane, was a triangular blackberry thorn one-third of an inch across. On separating the appendix from the ensheathing omentum a few drops of pus were seen. On Jan. 14th there was a fæcal fistula; the patient was still feverish. On the 28th there was still some elevation of temperature at night; the fistula was closed. During the next week it reopened; a small abscess burst at the umbilicus. On Feb. 19th the fever was high and a median incision below the umbilicus let out pus. He continued with discharging sinuses and hectic fever. On April 3rd the chest wall in front of the liver bulged and was red and tender; on the 5th a subphrenic abscess was opened here. Actinomycetes were found in the pus; search in the pus of the other wounds also revealed them. The boy was now very ill. On April 16th he left the infirmary. Three weeks afterwards he died. There was no necropsy.

CASE 4.—A female, aged 16 years. The patient lived in the country. She was admitted on Nov. 20th, 1905, complaining of abdominal pain and a sinus. In June, 1904, a painful swelling formed in the right iliac fossa which spontaneously discharged. She then went to a cottage hospital where she remained for ten months. On four occasions abscesses about the appendix region were opened; the last of these was a large one behind the great trochanter. At one time an appendicular concretion came away. The sinuses all closed. On admission the general condition was good; there was no fever. The chest was normal. There was a discharging sinus midway between the umbilicus and pubes; there were healed scars over the appendix and behind the hip. The hip-joint moved freely. The spine was normal. A week later, the temperature rising a little, chloroform was given and the abdomen was opened in the appendix region. Enormous matted adhesions were found occupying the whole right lower abdomen, and nothing was done. The wound healed but the fever still rose; during December the wounds in the groin and back of the hip broke out again. On Dec. 22nd a median incision was made from the umbilicus to the pubes; the peritoneum was half an inch thick and very adherent to the omentum and bowels. There was an extraordinarily dense mass below it. The appendix was found sloughed off one inch from its base; it was ligatured. The mass was adherent all round the cæcum. The sinuses, which led to the appendix, were scraped. She went steadily downhill, with high fever and free suppuration. An abscess was opened near the umbilicus. On Feb. 2nd dulness was found at the right base; this eventually developed into a subphrenic abscess, which was opened on March 8th but only one drachm of pus was found. On March 23rd the subphrenic region was again explored in front and behind but to no purpose. Soon after this actinomycetes were found in the pus from all the abdominal sinuses. The patient gradually wasted away, with a temperature of 103° every night. On May 5th she went home and died three months later. There was no necropsy.

CASE 5.—A female, aged 25 years. She was admitted on May 14th, 1907, complaining of a painful lump in the abdomen. Eight years previously she had had appendicitis; she was admitted to this institution and an operation was performed. Plastic adhesions surrounding the appendix were then found and nothing was done. Since then she had, on the whole, been fairly well, but had occasional pain for years past in the same place. During the previous fortnight this had been worse and the lump had been noticed. There was no vomiting; the bowels were costive. On admission she was found to be slightly built, pale, and thin; she was very short. The temperature was 99° F. and the pulse was 90; the tongue was clean. The chest was normal. There was a hard, well-defined, tender mass of the size of a cocoanut in the appendix region; the skin was not involved. The rest of the abdomen was normal. A diagnosis of actinomycosis of the appendix was made and on May 17th operation was performed. The bowels were found to be densely adherent to the anterior abdominal wall and an attempt was therefore made to get into any abscess cavity by working from the outer side behind the peritoneum. A spongy abscess was thus entered lying behind the cæcum; from this pus containing yellow granules was evacuated; these on microscoping and cultivating proved to be actinomycetes. A tube was put in. Three days later the sinus became fæcal but only for a day or two. No improvement resulting, a further operation was performed in June and more pus let out. Again the wound became fæcal. On August 26th a large hole in the cæcum was sewn up; the appendix was not found. She died on August 30th. There was no necropsy. All five

LONDON: SATURDAY, SEPTEMBER 14, 1907.

The Plague in India.

IT appears that the net result of the two years' consideration by the Government of India of the proposals of the Royal College of Physicians of London is to condemn the recommendation of the College that a special organisation for dealing with plague should be formed, but to admit that a general sanitary service requires development.[1] Further than this there is apparently no progress, for Mr. MORLEY was still awaiting information regarding proposals in this direction when he penned the dispatch on July 26th, calling attention to the importance and urgency of the question, expressing his anxiety to be placed in possession at the earliest date of the view of the Indian Government, and recording his regret that greater expedition could not have been found practicable. Possibly the Secretary of State for India had also in mind at the time of his dispatch the questions which Dr. H. V. RUTHERFORD had asked so long back as April last concerning the strength of the medical staff specially deputed for plague work in India, the answers to which he was still awaiting, although three days at most would have been ample time for collecting the information. Things must move slowly in India when it takes over three months to learn what is the actual establishment devoted specially and wholly to plague work. We suspect that some of the active and passive resistance to reforms which Lord KITCHENER experienced in his proposed reorganisation of the Indian army, and which he successfully overcame, has now been transferred to the equally urgent and necessary reforms in the sanitary organisation in India. The particular name or form of the proposed sanitary organisation is a matter of small moment provided the service so formed is the very best for combating plague in India, and that it is formed quickly. We hope, however, that it will be the outcome of proposals by medical officers of great and practical experience in plague and sanitary work and not a cut-and-dried scheme from the secretariat in India, the source of many different plague policies. We further trust that in any scheme of development of a sanitary service it will be recognised that in dealing with qualified Indian medical men and women trained in preventive medicine a corresponding status in the service must be given to them according to the responsibility placed on them. It is only by ungrudgingly treating the Indian sanitary service as a great and important branch in the Civil Service of the country that the best work will be obtained from it. The fewer sanitary inspectors there are probably the better. Sanitary inspectors are not usually a success in the East; monetary considerations are liable to destroy their utility. Doubtless the creation of a separate public health service in India will have a dislocating effect on the existing medical and sanitary administration of the country. Evidently the Royal College of Physicians foresaw this contingency, for no radical changes were recommended, but a scheme embodying a slow and progressive development towards the attainment of a separate and special department the sole duty of which in the first instance should be the prevention and mitigation of plague epidemics while this disease continued its ravages in India.

Let us turn to the recently published correspondence between the Government of India and the Secretary of State for India for information as to the views held by the former.[2] One of the main objections put forward by the Government of India to the organisation proposed by the Royal College of Physicians is its unsuitability to India, but the papers relating to the Punjab show that this province actually possesses on a very small scale an organisation not dissimilar from that which the Royal College of Physicians recommended. The province is stated to have a special plague staff consisting of ten medical men belonging to the Indian Medical Service, four physicians sent out from England, and a subordinate staff of 23 assistant surgeons and 38 hospital assistants. The difference between this and the scheme recommended by the Royal College of Physicians lies in the fact that in the latter qualified women are added, and the suggestion is made that there should be, to begin with, a similar organisation for at least four or five centres, that these centres should be used as training places for other medical men and women in order that other fresh centres could be formed where most needed, and that in this way a special plague organisation should be brought into being and developed. It is not likely to be contended seriously that 14 medical officers with a few native assistants can cope in the slightest degree effectually with such an epidemic as that which has been prevailing in the Punjab during the past seven years, even when there are added to this special organisation the 29 civil surgeons with their other duties. The Punjab is slightly larger than Great Britain. It is divided into five divisions, has 29 districts, and 140 small towns. It is only necessary to state these facts to make clear the absurdity of attempting to combat one of the worst epidemics known in history with 14 medical men and their assistants.

In the Madras Presidency, where plague has been kept under reasonable control, it is stated that the Royal College of Physicians' "scheme is for all practical purposes not materially different from that which is now in existence in this presidency," and we learn later that a sanitary organisation was begun in 1895—i.e., a year *after* a sanitary service was recommended to the Government of India by the Medical Congress held in Calcutta in 1894. A similar reply comes from the United Provinces of Oudh and Agra. So that in at least three provinces the principle of the proposed organisation has already been accepted and is in operation, which are facts that do not consort well with weeks afterwards in the neighbourhood, especially if a subphrenic abscess or abscess of the base of the right lung is suspected, actinomycosis should always be considered a very probable cause. Another point in the diagnosis of the condition is the spongy character of the abscesses, so that very little pus may be got from a large swelling. This character is not present when there is a considerable secondary infection with pyogenic organisms.

---

[2] Correspondence regarding Measures for the Prevention of Plague. Wyman and Sons, London. 6½*d.*

The actual confirmation of the diagnosis, of course, depends on the finding of the ray fungus. It is best seen in a thin layer of pus running down inside a test-tube, the yellow granules, about as large as a pin's head, sticking to the glass. These should be put on a slide, covered with a cover-slip very gently pressed on, and examined unstained. They form transparent areas to the naked eye. The further diagnosis rests with the microscopist.

Sometimes this affection may resemble tuberculous or malignant disease of the cæcum, but in actinomycosis the mass is larger, more fixed, and there are no obstructive symptoms. It may also be confounded with psoas abscess.

PROGNOSIS.

In my opinion this is much less favourable than English writers have admitted. My own cases have been particularly unfortunate, every one of the five having eventually died. In giving a prognosis the relapsing nature and long duration of the disease are to be taken into serious account. Gangolphe's case when he reported it was said to be recovering; he soon after died. One of my cases was sent out "well"; she came back and died a year later. A patient at St. Bartholomew's Hospital, reported by Waring, was sent out apparently cured but went back and died. A patient of Blascko, reported by Israël, relapsed and died after two years of apparent cure. One of my cases was operated on for appendicitis eight years ago, and though there had been symptoms ever since and a large mass was present that must have taken many months to form only lately has she been seriously ill.

Of 77 cases Grill quotes 22 cured, 10 relieved, and 45 dead. Of 68 cases (overlapping the above to some extent) Löwe quotes 12 cured, 36 dead, and 20 under treatment. Of 13 recent cases 4 have recovered and 9 died. We may conclude, then, that more than two-thirds of the cases die and that even those reported cured are liable to relapse. Most of the so-called cures have been watched for a very short time. Volkmann and Hochenegg have each followed cases for five years, still quite well. When extensive sinuses have formed, with fœtid pus, recovery is nearly hopeless, and the appearance of disease in the lungs or liver is equivalent to a death-warrant. The disease is usually miserably chronic and may last for years. One case died in 24 hours and several have run their course in a month. The average is about nine months. Erving's case lived 13 years.

TREATMENT.

Having regard to the very grave outlook, a determined attempt should be made completely to remove all foci of the infection if the patient comes under treatment soon enough, and unless such removal is quite impossible the surgeon should be prepared even to sacrifice the cæcum and neighbouring bowel, perhaps with temporary formation of an artificial anus. There is a strong temptation merely to open abscesses and this usually allows the patient to become doomed. Unfortunately, it has generally been found quite impossible by a reasonable sacrifice to eradicate the disease. All that can then be done is to open abscesses as they point. Potassium iodide in large doses is usually given; the wounds may be washed out with diluted tincture of iodine. Illich, von Eiselberg, and Friedrich claim great success with injections of tuberculin. Arsenic and calomel appear to have done good. Waring recommends peroxide of hydrogen as the best application for the sinuses.

I most cordially acknowledge the kindness of Mr. J. Paul Bush, Mr. G. Munro Smith, Dr. J. Swain, and Mr. T. Carwardine in allowing me to publish cases from their wards. Mr. T. H. Kellock also very kindly gave me some details of his cases by letter.

Bristol.

TWO CASES OF ACUTE TUBERCULOUS CEREBRO-SPINAL MENINGITIS.

By T. STACEY WILSON, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM;

AND

JAMES MILLER, M.D. EDIN., M.R.C.P. EDIN.,
VISITING PATHOLOGIST TO THE GENERAL HOSPITAL, BIRMINGHAM
LECTURER ON BACTERIOLOGY, BIRMINGHAM UNIVERSITY.

THE first of the two cases dealt with in this paper is one of very considerable clinical interest owing to the unusual course which the disease took and the rapid way in which the symptoms developed.

CASE 1.—The patient was a young and apparently healthy country girl, aged 17 years, who was in domestic service in Birmingham. The history of the onset of her illness, as given by Mr. A. E. De Vall of Saltley, with whom one of us saw the case in consultation, is as follows. On March 29th she went to see him, complaining of sore and congested but not ulcerated throat, vomiting, and pains in the limbs and in the back of the neck. The clinical picture was typical of influenza. Three days later he saw her at home and found her about the same but with the addition of headache and constipation. On the next day the vomiting ceased but pain over the bladder was complained of. On April 4th she still had pain over the bladder, and the lower limbs seemed very tender and she did not seem able to move them freely but there was no suggestion of any paralysis. The temperature was 100° F. For the next six days she remained in much the same condition and enteric fever was suspected as the spleen was enlarged slightly, the temperature oscillating between normal and 100°, and the patient being at times delirious. The pains had ceased in the arms but there were still pain and tenderness in the legs. On April 10th, 13 days after the onset of her illness, the tenderness of the legs increased and she could not move them without great pain. On the following day retention of urine supervened and the bowels were moved involuntarily and she became more drowsy and apathetic. On the 13th she had a slight convulsion involving the right side only which lasted some few minutes and was followed by unconsciousness for half an hour. A report upon the blood had been received from a trustworthy laboratory and Widal's reaction was stated to be positive. The

the Beelzebub, "Lord of the Flies." The proverb that "Dead flies cause the ointment of the apothecary to send forth a stinking savour" also bears witness to the antiquity of the evil and to the antagonism between the insects and the medical profession. In this country they are regarded merely as a minor nuisance, an enemy from whom meat has to be guarded rather through fear of resulting maggots than from any danger of more subtle contamination. It might even be suggested that they were useful as scavengers, clearing up all sorts of refuse; but this credit can scarcely be given to them, as they tend to wander rapidly from one source of food to another rather than to stay and to finish up any one delicacy; while it is probable that infective microbes would pass through the alimentary canal of the fly alive and would be deposited in undiminished virulence in some fresh spot, together with their excreta. Regarding flies, then, as potential carriers of infection, two factors have to be taken into consideration, the existence of foci of contamination to which they have access and the possibility of their transferring the contagium to mankind or the lower animals. The principal human diseases prevalent in this country which flies have been accused of spreading are enteric fever and epidemic summer diarrhœa. In both of these the infective agent probably generally leaves the body of the patient in the stools and conveyance of infection to others by flies implies that these insects have access to fæcal matter. In ordinary circumstances this seems hardly likely to occur where there is a well-organised system of water drainage, though perhaps filter-beds at sewage farms may offer opportunities for such infection. It is otherwise in such places as still employ dry systems of sewage disposal, and attention was forcibly directed a few years ago to the resulting danger by Mr. A. W. MARTIN,[4] medical officer of health of Gorton, where the "privy-midden" system was in operation. In his opinion flies were largely responsible for the prevalence of the diseases just mentioned. In the case of epizootic diseases there would seem to be greater danger, since flies may settle on the dead bodies of animals which have succumbed to such affections as swine fever, anthrax, and glanders and may readily convey infection to the feeding troughs of others. Probably so long as the carcass remains entire the risk of the insects becoming contaminated with bacteria is small, but it is important that infective material should be destroyed by fire or, at all events, deeply buried as soon as an inspection of the carcass has been carried out. To insure due care in such cases it is desirable that the reality of the danger arising from this mode of conveyance should be generally recognised. Dr. BUCHANAN has done good work in proving experimentally what had previously been largely a matter of surmise. From the domestic point of view also the problem of preserving food of all kinds from the attentions of flies becomes one of greater urgency. Hitherto it has seemed but a small matter. But if *de minimis non curat lex*, science has proved that it is by attention to what appear to be small things that the greatest results may be achieved, and in this case a little forethought may avert serious danger.

[4] Public Health, 1902-03, xv., p. 652.

Lancashire Sanitation.[1]

IT is just over 30 years since the passing of the Public Health Act of 1875, a period of time supposed to correspond with a generation of human beings, and it might be hoped that sanitary knowledge had now become so widely diffused that it would be difficult to find any traces of the old condition of things, when drains were primitive or non-existent, houses often barely fit for habitation, and dairies and bakehouses managed with no regard to cleanliness or health. Unfortunately, such a hope is far from realisation even at the present day. In too many parts of the country progress has been slow and uncertain: money is more valued than health and the most necessary measures of sanitation are often neglected when they involve an addition to the rates. Instances of such parsimony are within the knowledge of all, but documentary evidence is also available in the reports made from time to time to the Local Government Board by its inspectors who are sent to investigate the sanitary condition of individual localities. A batch of such reports has recently been issued, dealing with a group of districts in Lancashire and the condition of things revealed in these papers is such as to cast a slur on the civilisation of a country in which they are possible. It is amazing to find that in the very suburbs of Manchester, in the district of Droylsden, over three-quarters of the houses are supplied only with midden-privies in place of water-flushed closets, that many houses are built with windows that are not made to open, and that indescribable filth is prevalent in many of the poorest houses. But this state of things is by no means confined to the district just mentioned. Midden-privies are common at Limehurst, Denton, and Failsworth. At Lees we are informed that 870 houses have only 685 closets of any sort between them and that groups of 13 or 14 houses exist with only four closets to the group. In several districts there is no isolation hospital for infectious cases other than small-pox: at Failsworth only eight out of 62 cases of scarlet fever were removed from their homes for treatment. Back-to-back houses are found in some of the districts with no possibility of through ventilation; common lodging-houses are allowed to be kept in a filthy and insanitary condition. What wonder, then, that infantile mortality is high in these areas where not only do the women go out to work in the factories but home conditions are such as has been described. And if the human habitations are so neglected can it be wondered at that the cowsheds are noted as unsatisfactory. It is altogether a shameful and distressing condition of affairs to exist among us at the outset of the twentieth century.

Lamentation over our backslidings is, however, unprofitable unless it leads to efforts at improvement, and with this object it is advisable to endeavour to establish the actual causes which lead to such hygienic failures. It is not difficult to discover some at least of the defects at present existing. First and foremost the position of the medical officer of health must be altered. He upholds in each district the teaching of science; to him the local governing lumbar puncture showed increased pressure and signs of spinal meningitis. As the patient was rapidly getting worse and there were signs of increased intracranial pressure he was trephined on the right side, above and behind the ear. Nothing beyond the increased intracranial pressure could be detected. He died on the following day and the post-mortem results were as follows.

---

[1] Reports of Medical Inspectors of the Local Government Board. Nos. 263-268, 270, 271, and 273 (districts of Droylsden, Denton, Mossley, Failsworth, Lees, Hurst, Audenshaw, Ashton-under-Lyne, and Limehurst). 1907. Wyman and Sons, Limited, Fetter-lane, E.C.

Necropsy.—The post-mortem examination was held on May 12th. The whole body was examined. There was a trephine opening on the right side behind the ear. The lower lobe of the left lung showed collapse and dilatation of the bronchioles. The rest of the lung and the organ on the right side showed no obvious change. At the base of the left lung there was an enlarged gland with grey areas scattered throughout and one large necrotic focus. Microscopically the gland showed typical areas of giant cell formation and caseation. Tubercle bacilli were found in considerable numbers. The liver showed marked cloudy swelling with irregular paler areas scattered through it. The kidneys showed a similar condition. The spleen was enlarged, soft, and flabby. Microscopically these organs showed no change of special interest. The arterioles of the spleen, however, showed hyaline degeneration. With regard to the spinal cord, on opening the dura mater a large amount of turbid fluid was found. On microscopic examination polymorphonuclear and mononuclear leucocytes and endothelial cells were found in large numbers, also a few tubercle bacilli. The pia arachnoid was pale and the vessels appeared thickened but there were no tubercles. Sections of the cord showed well-marked inflammation of the pia arachnoid. There was exudation of a fibrinous-looking fluid containing numerous cells, chiefly mononuclear, but also polymorphonuclear. The cellular infiltration was most marked around the vessels and nerves. In places the cells were aggregated into definite tubercle follicles with occasional giant cells. Not infrequently the nerve roots were seen invaded by such cellular areas. Tubercle bacilli were fairly numerous in the giant and epithelioid cells. The white matter of the cord showed some cellular infiltration towards the periphery but this was not so marked as in the previous case. Early degenerative changes were to be found in the cells of the grey matter. Marchi specimens showed disseminated degenerative changes in the nerve roots and towards the periphery of the white matter but these were not nearly so marked as in the previous case. As to the brain, on opening the dura mater the convolutions were found much flattened and the vessels injected. There was a great excess of turbid fluid towards the base of the brain. There were irregular areas of opaque exudate to be seen in the subarachnoid at the base extending up the Rolandic fissures on either side and also over the vertex. The ventricles were distended with turbid blood-stained fluid. For microscopic examination portions were taken from both Rolandic areas, from the vertex, the cerebellum, and the pons. All showed a well-marked meningitis with sero-fibrinous exudate containing numerous cells with occasional areas of necrosis. Tubercle bacilli were found in these. No giant cells were found. There was some degree of cerebritis immediately under the pia arachnoid. Both middle ears contained seropurulent fluid. Suitably stained preparations showed numerous diplococci but no tubercle bacilli.

The second case is somewhat similar to the first but the changes are more marked in the brain than in the cord. Further, there is a source of infection in the caseous bronchial gland and probably also in the middle ear.

The reports of the post-mortem examinations are by Dr. J. Miller.

Birmingham.

OBSERVATIONS FROM THE SOUDAN.

BY L. BOUSFIELD, M.A., M.D. CANTAB.,

LIEUTENANT, R.A.M.C.; BIMBASHI, EGYPTIAN ARMY.

I.—MEMBRANOUS ULCERATION, DUE TO SPIROCHÆTÆ, SIMULATING DIPHTHERIA.

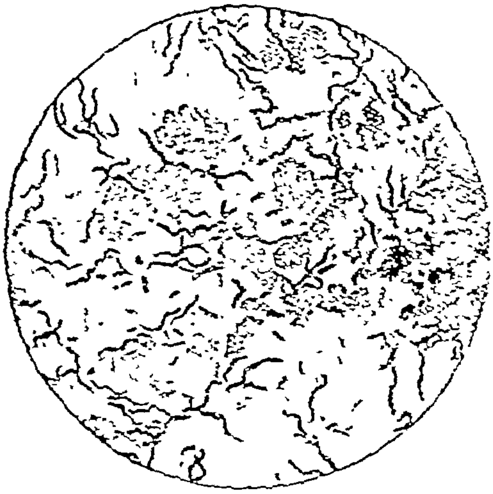
THE words "due to spirochætæ" appear in the heading of this article, though perhaps they should be replaced by the expression "associated with the presence of spirochætæ" as I have not yet attempted to produce the condition artificially, and so it cannot be stated definitely that spirochætæ are the exciting cause. However, there is good reason for considering that this condition is caused by spirochætæ in that they appear in enormous numbers in the swabs taken from the ulcerations and in some cases practically in "pure culture," though always associated with the bacillus fusiformis. Some films show such vast quantities, twined and matted together, that only at the periphery is it possible to examine individuals carefully.

The condition resembles closely, or is the same as, that described by Vincent[1] in 1898, but these cases seemed worthy of being placed on record for three reasons: first, this condition has not, as far as I know, been reported from this region; secondly, four similar ulcers in the buccal cavity and three (?) from the conjunctival sac are here described; and thirdly, there are certain differences between the three tonsillar cases and those reported by Vincent.

These differences are now given: 1. Fœtor was evident in his cases, while this was absent in all enumerated in this article. 2. His cases were practically all unilateral, while two out of three were bilateral. This point is of importance, for H. W. Bruce[2] states that mild cases are invariably unilateral. 3. Vincent mentions that bacilli fusiformes were sometimes unassociated with spirochætæ and often outnumbered them. In these cases the two were always associated with one another and the spirochætæ usually enormously outnumbered the bacilli. 4. Pyogenic cocci were almost invariably present in his cases, while in several cases of this series the infection was practically pure with spirochætæ and bacilli fusiformes. 5. He mentions extension to the soft palate and uvula, and in none of my cases was this present, perhaps owing to the cases being seen early in their course. 6. Vincent makes no remark about the urine, but Bruce mentions albuminuria in one out of ten of his cases. Albumin was present in two out of the three cases of tonsillitis mentioned in this article.

The number of cases is small and contains the following types: (a) Tonsillitis—(1) unilateral, one: and (2) bilateral, two. (b) Ulcers in buccal cavity—(1) opposite the last molar tooth of the lower jaw, three; and (2) in front in the lower fold of the mucous membrane, one.

The best way of describing this condition will be to give a *précis* of one case. An Egyptian nafar (soldier), aged about 23 years, reported sick with a sore throat. He stated that he had had a sore-throat for about 24 hours but beyond that made no complaint. On examination a thick yellowish-white membrane of about the size of a sixpenny piece was found adherent to the left tonsil. On removing the membrane a bleeding surface was exposed, showing considerable destruction of the underlying tissues. The ulcer thus formed was deep with ragged edges. The glands behind the left angle of the jaw were slightly enlarged and tender. The pharynx was not generally inflamed to any marked degree. His temperature was 100° F., his pulse-rate



Reproduction of a micro-photograph of a pure infection stained by methylene blue. Many spirochætæ in the field did not appear on the negative. The bacilli are bacilli fusiformes. No large clumps of spirochætæ appear in this field. The photograph was taken by Sergeant A. Gibbons, R.A.M.C. Objective 1/12; ocular No. 8.

[2] H. W. Bruce: Vincent's Angina, THE LANCET, July 16th, 1904, p. 155.

which are "greened" with copper salts and which do not contain an excessive amount of copper will be admitted to entry provided that the label bears a statement that salts of copper have been used. It seems to us that the American Government is convinced that the best policy is that which we have consistently urged for years in regard to all questions of fraud and adulteration, and that is to insist upon the use of an honest label. England has no statute applying to the prohibition or limitation of preservatives or colourings in food, but it still has the recommendations of a departmental committee which were drawn up six years ago! And so in 1907 the principal chemist of the Government laboratory is compelled to write in his report, which we noticed in our issue of August 24th, p. 542, "The figures show that butter frequently contains boron preservative in excess of the amount recommended as the limit by the Committee on Preservatives in Food, but in the absence of legislation on the point and in view of the conflicting decisions in the courts I have been unable to advise that proceedings should be taken." In the American bulletin it is stated that the views of "eminent physiologists, hygienists, health officers, and physicians in the United States" were obtained as to the propriety of using preservatives in food and a tabulation of these views points "overwhelmingly to the fact that preservatives, as a class, are injurious to health and hence their use is under the Act inhibited." THE LANCET, on its own initiative, collected similar evidence over ten years ago, but *festina lente* applies more to English than to American methods.

THE FOURTEENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE Fourteenth International Congress of Hygiene and Demography is to be held in Berlin from Sept. 23rd to 29th, and Dr. Nietner, the secretary-general, asks us to give publicity to the following. Up to the present 2500 applications have been received from intending members of the Congress. As the number of applications on such occasions always grows larger and larger in the course of the last weeks previous to the meeting there may be some difficulty in procuring suitable lodgings. For that reason, and also to facilitate all necessary preparations, intending visitors are respectfully but urgently requested to send in their applications as soon as possible. As a large number of the members of the Congress are already on their way it has not been possible to send the last "conclusions" to the members living in distant countries. Members will, however, be handed everything they require in connexion with the Congress on calling at the office on their arrival. Dr. Nietner's address is 9 W., Eichhornstrasse 9, Berlin. Prince Heinrich von Schönaich Carolath has been elected President of the Congress. The Vice-Presidents are Professor Rubner, director of the Hygienic Institute of the University of Berlin, and Professor von Meyr of Munich. Several *Festschriften* will be printed and presented to the members of the Congress. The Imperial Statistical Office and the Imperial Health Office will issue jointly a volume entitled "The German Empire from a Hygienic and Demographic Standpoint." The Royal Prussian Cultus-ministerium (Ministry of Education) will present two volumes to the members of the Congress, of which one deals with measures for preventing the spread of epidemics whilst the other gives a description of the new premises of university clinics, laboratories, and other medical institutions of various Prussian universities. The city of Berlin will contribute a work on the Hygiene of the Metropolis. Every member on his arrival will receive a guide-book with a short description of about 120 hygienic and other institutions over which the members are to be shown. This guide-book is in German, French, and English. A committee, including the leading members of the medical profession of Berlin and representatives of the various medical societies, of the medical faculty, and of the Army Medical Corps, has been formed for the purpose of showing attention to the members of the Congress on behalf of the Berlin medical men. The committee has decided to arrange a reception on Sept. 28th in the Exhibition Hall, Hardenbergstrasse, where there is room for several thousand guests.

ALCOHOLISM AND CIRRHOSIS OF THE LIVER IN CHILDHOOD.

THE pathology of the coroners' courts as reported in the lay newspapers is frequently something to wonder at and recks but little of text-books or authorities. The reason is perhaps not far to seek. The medical practitioner in giving his evidence usually strips it so far as possible of technicalities in order to make clear to the members of the jury the conditions found by himself during his attendance on the case or at the post-mortem examination, while the coroner, if he happens to be a medical man, not infrequently further explains any obscurities. The brief abstracts published, however, often enable but little exact information to be drawn by those reading them. A recent case in point may be quoted in illustration. At the inquest on a child, aged three years and nine months, it came out in evidence that she had swallowed a considerable quantity of gin, apparently about two and a half fluid ounces and that when seen by a medical practitioner she was found to be unconscious and suffering from general convulsions. These were relieved by the administration of chloroform but death eventually occurred. The post-mortem examination, which was performed by Dr. L. Freyberger, appears to have revealed a condition of cirrhosis of the liver, which was hobnailed and weighed 16 ounces, while the spleen and the kidneys were firmer than usual, and in one report it is stated that the "child had an adult brain," whatever that may mean. Both Mr. H. Wheelwright, the practitioner in attendance, and Dr. Freyberger stated that death was due to failure of respiration following acute alcoholic poisoning and that the changes found post mortem could not be produced by a single dose but were those usually associated with chronic alcoholism. The coroner after the medical evidence adjourned the inquest in order to make inquiry regarding the parents, since the conditions found strongly suggested that this occasion was not the first on which the child had taken alcohol. At the adjourned inquiry evidence was forthcoming that the parents bore a very good character both in their business and domestic relations. An inspector of the National Society for the Prevention of Cruelty to Children said that they had "the highest of reputations for kindness to their children" and that he could not trace any fact pointing to the child having taken alcohol before. The coroner, in summing up, said that there must be a certain amount of doubt in the case and that the high character of the parents made it very perplexing when taken into consideration with the medical evidence. It may be of some interest briefly to consider the occurrence of cirrhosis of the liver in children, which, though rare, is well recognised as occurring. 65 cases were collected by Howard and 53 by Laure and Honorat, but in such groups the ages of the children have usually been between nine and 15 years. In a considerable proportion of these cases no cause could be found, although alcoholism was traced as a cause in 15 per cent. of Howard's cases. One special form of true cirrhosis in children is due to syphilis and has been described as parasyphilitic cirrhosis of children. In infancy and early childhood the condition is more rare and although some cases are due to syphilis, in others the actual causation eludes discovery. The view is gaining ground that alcohol is not the direct and only cause

The various treatments employed were: 1. Dusting with boric or iodoform powder. 2. Hot boric fomentations every three hours. 3. Hip bath with perchloride of mercury solution ($\frac{1}{1000}$) three times daily for from one to one and a half hours at a time; on one occasion a local bath was used for 24 hours consecutively, at the end of which time the patient presented symptoms of poisoning (intestinal cramps, vomiting, and diarrhœa). 4. Lysol and carbolic baths. 5. Cauterisation with silver nitrate stick. 6. Very extensive scraping followed by swabbing with pure carbolic. 7. After all these methods had failed mercury and iodides with local antiseptic treatment were given without any results (second case.)

It spite of treatment the condition spread continuously and steadily and the first two cases seemed to get well owing to the destructive process coming to a natural end rather than to a termination procured through treatment. The third case came to hospital and proceeded just as the others had done, and after some weeks about one and a half inches of the penis had been destroyed and the only hope seemed to be that nature would step in and cause the process to end. Fortunately, a new Egyptian medical officer took charge of this ward, and he suggested trying turpentine. This was accordingly done, and the ulcer, which had been spreading imperceptibly but steadily for nearly one and a half months, began at once to present a more healthy appearance and was almost healed in a week. The oil of turpentine was applied on small lint pads to the ulcer. The oil of turpentine was probably old, but how old I cannot say, nor do I know whether it was American, German, or other particular kind; these points are mentioned because the properties of turpentine are said to vary both with age and with the species of pinus from which prepared. Perhaps the curative action was due to hydrogen peroxide, which turpentine produces with air in the presence of water. Unfortunately, no new cases have come under observation and so it is difficult to say whether the rapid healing was a coincidence or really due to the action of this drug; however, the Egyptian medical officer stated that he had treated other similar cases with this drug with like good results.

This seems worthy of recording, since the results of this type of ulceration are appalling, and if met with in other parts of the world the treatment by turpentine (or perhaps hydrogen peroxide) might be of great value.

Very few cases of phagedæna of the penis have come under my observation and none in the Soudan, and in these the condition was very rapid, showing much sloughing; the patients were debilitated and presented symptoms of toxic poisoning. These cases presented an entirely different picture, the destructive process continued imperceptibly but steadily week by week, and in the first patient month by month; the patients were not debilitated, and showed practically no signs of toxic poisoning.

In dealing with natives it is often difficult to know whether they are carrying out orders when one's back is turned, but in these cases the anxiety shown by the patients at the possible total loss of an important organ was very evident and there was no reason to believe that the various treatments were not thoroughly and conscientiously carried out.

I was unable to find out whether these ulcers resulted from sexual intercourse, but in all probability they did. Whether such a condition obtains amongst the female population I do not at present know.

There was no reason at any time in any one of these subjects to raise the diagnosis of epithelioma, and the subsequent course disproves such a condition. Further, malignant disease, from my own observations and from what has been told me by medical men of large experience in this region, is extremely rare amongst the natives of the Soudan.

THE BRISTOL GENERAL HOSPITAL.—The half-yearly meeting of the governors of the Bristol General Hospital was held on Sept. 9th under the presidency of Mr. J. S. Fry. The chairman stated that the daily average of in-patients for the past six months was 180·6, the highest on record. The financial statement was satisfactory. £16,210 have been received towards the special appeal made for the sum of £18 000 which was required for carrying out several much-needed improvements in the institution. The chairman alluded in sympathetic terms to the great loss which the hospital had sustained through the death of Dr. E. Markham Skerritt, whose "life had been well and wisely spent."

IRREGULARITY OF THE PULSE IN DIPHTHERIA.*

BY OWEN H. PETERS, M.D., CH.B. MELB., D.P.H. LOND.,
RESIDENT MEDICAL OFFICER, CITY ISOLATION HOSPITALS, NOTTINGHAM.

THE well-known occurrence of heart symptoms in diphtheria naturally leads the practitioner to pay special attention to the pulse, with the result that many a casual observer has regarded the frequent occurrence of irregularity as the most striking feature of the pulse in diphtheria. It will be shown that this fact has, however, little special significance and is really due to the great incidence of the disease in children, especially those of from four to five years of age, who appear commonly to exhibit this symptom after any febrile disturbance and often in apparent health.

An examination of the literature of diphtheria will impress one with the great importance attached to this sign wherever and whenever it occurs. It never seems, however, to have occurred to writers or clinical observers to doubt but that all irregularity of the pulse was the specific effect of the disease in question. No notice has been taken of the fact that it is so common in other diseases of childhood, and its comparative absence in adult cases seems to have been passed by without comment. All forms of irregularity being thus grouped as of an equally serious nature, it will be understood that some have gone so far as to suggest that patients should be kept in bed at least three months should any irregularity continue.[7] Estimates as to the percentage occurrence of irregularity of the pulse in diphtheria differ widely. Hibbard,[2] in a review of 700 cases, gives 10 per cent., but adds that "some cases were doubtlessly not recorded." The usual quotation is, however, much above this figure, and Villy,[3] who carefully followed out 177 cases, found it as high as 87·5 per cent. That this does not overshoot the mark is suggested by my own observations in 92 cases laboriously examined throughout the stay in hospital; over 80 per cent. were found to have had at some time definite irregularity. The wholesale occurrence of this sign at once suggests the inquiry as to what extent it might be attributed to specific affection of the heart.

In order to determine this point a comparison was established between cases of diphtheria and scarlet fever. This might be considered an instructive comparison, since there is a great contrast between these diseases as regards their cardiac effects. Scarlet fever does not seem to have much effect upon the myocardium if we are careful to select those cases only where the temperature falls in seven or eight days with no complications. So that with such a selection the toxin of each disease has acted for a similar time. When the temperature is sustained, as it often is, for a much longer period, and especially with adjacent pericarditis and endocarditis, there is then the real danger of serious myocarditis in scarlet fever. Pathological findings seem to confirm this view. A comparative investigation has recently been made by Aschoff[4] and Tawara of the changes in the heart wall in 112 cases taken from 13 different diseases. "Amongst these different groups of diseases it was only in the cases of diphtheria that at all regularly distributed parenchymatous modifications were found. In the cases of scarlet fever, measles, tuberculosis, &c., no alterations worth mentioning were found. In our typhoid cases in particular we practically failed to find any interstitial reaction contrary to the published statements with regard to the frequency with which myocarditic alterations occur in typhoid." This quotation is interesting as establishing a comparison between diphtheria and the other infectious diseases in the intensity of the cardiac affection and is the more valuable as the work was all done by one individual. In comparing the two diseases 92 cases of diphtheria and 95 of scarlet fever were taken consecutively from those that recovered in the order of admission into hospital after excluding protracted cases of the latter disease and those with pericarditis and endocarditis. They were arranged in two groups according as the pulse had been "regular" or "irregular" at any period throughout the disease. An easy standard was taken for the first group; those pulses that had been noted as slightly irregular on two or three occasions only were classed as "regular." All others were classed as "irregular." The arrived she was exsanguine and was not breathing. There were clots in the mouth and nares and signs of vomiting on the clothing. Adrenalin and normal saline solution were injected subcutaneously and artificial respiration was employed, but without avail. At the necropsy, which was performed 19 hours after death, both nostrils and the right auditory meatus were found filled with clotted blood. Below and behind the meatus was a swelling of the size of an olive, over which the skin was ecchymosed. The meninges and brain were normal. The venous sinuses, including the right lateral sinus and bulb, were intact. The whole temporal bone with a large amount of the soft tissues beneath and a portion of the wall of the pharynx were removed and hardened for 48 hours in 10 per cent. solution of formalin. A stream of water could be forced through the carotid canal without finding its way into the tympanum. The soft tissues beneath the bone which contained the carotid artery and jugular veins were infiltrated with blood and there was a large hæmorrhagic extravasation which communicated with the pharynx a short distance below the mouth of the Eustachian tube. The extravasation extended outward to the angle of the jaw, undermined the subcutaneous tissue, formed the swelling previously mentioned, and communicated with the lumen of the external auditory canal. The tympanic membrane was intact but was retracted and united to the promontory, evidently as the result of an old perforation. The tympanum and Eustachian tube contained much exudation but no blood. Attached to the walls of the tympanum were several small polypi. The attic and mastoid cells were filled with exudation but were not necrotic. Microscopic examination revealed the characteristic appearances of chronic suppurative otitis media. The carotid artery was normal but its sheath showed chronic inflammation as far as the first bend in the bony canal, most marked at the entrance of the latter. The sheath for a short distance was infiltrated with blood which had forced its way from the large hæmorrhage beneath the temporal bone. The soft tissues in which this hæmorrhage had taken place were involved in granulation tissues in which were large areas of pus cells. The wall of the jugular vein which passed through this abscess was necrotic, lined with purulent thrombi, and in places perforated. Sections of the abscess stained by Gram's method showed numerous streptococci but no other bacteria.

---

* The superior figures refer to the bibliography at the end of the article.

INFANT MORTALITY IN HUDDERSFIELD.

IT is not without interest to note the apparent effect on infant mortality of the local Act which was passed last year and enacted the early notification of births occurring within the borough of Huddersfield to the sanitary authority. The rate of infant mortality—of deaths under one year of age—in Huddersfield during 1905 was equal to 119 per 1000 births and rose during 1906 to 135 per 1000, the average rate in the 76 large English towns showing an increase from 140 in 1905 to 145 in 1906. Thus the rate of infant mortality in Huddersfield, which was 15 per cent. below the large urban rate in 1905, was only 7 per cent. below the same average in 1906. It must be remembered that the Birth Notification Act did not come into operation in Huddersfield until late in 1906, but bearing in mind the voluntary efforts made by the mayor and sanitary authority to promote early notification of births prior to the passing of the Act the figures noted above were somewhat disappointing. During the first six months of this year the rate of infant mortality in the 76 large towns was equal to 123 per 1000 births and the rate in Huddersfield did not exceed 97 per 1000; thus the Huddersfield rate was 21 per cent. below the mean large urban rate. The interesting point for consideration is whether this relative reduction in the rate of infantile mortality in Huddersfield during the first half of this year, compared with the mean rate in other large towns, can safely be attributed to the operation of the Huddersfield local Act. During the six weeks of unsummerlike weather and temperature ending on August 10th, which has checked the usual fatality of summer diarrhœa, the rate of infant mortality in our large towns has fallen to 96 per 1000, while in Huddersfield it has not exceeded 38 per 1000. The evidence of these statistics seems therefore to point to the successful administration of the Huddersfield local Act since the beginning of this year as the cause of the recent reduction of infant mortality in that town. In view of the new Act making early notification compulsory the effect of the local measure in Huddersfield on infant mortality acquires much importance.

FATAL HÆMOLYSIS FOLLOWING TRANSFUSION OF BLOOD.

IN November, 1906, Dr. Crile published in the *Journal of the American Medical Association* an important paper recommending as the best method of transfusion of blood anastomosis of the proximal end of an artery of the donor to the proximal end of a vein of the receiver.[1] Since that period the method has been tried in the treatment of anæmia in America at times with favourable results, at others without much apparent change. In the *Journal of the American Medical Association* of August 3rd Dr. William Pepper and Dr. Verner Nisbet have reported a case in which fatal hæmolysis followed—an observation of great importance because transfusion of blood has always been regarded as innocuous. A man, aged 33 years, was admitted to hospital on April 16th last. In October, 1906, it was noticed that his naturally pale complexion was becoming paler and tinnitus and nocturnal bleeding from the gums began. The bleeding gradually became more severe and took place both by day and by night for ten days preceding admission. Blood was also passed in the urine and fæces. 11 years before admission the patient had a hard sore on the penis which was followed by a rash, and he was treated for syphilis for six months. On admission the temperature was 93° F. and the pulse was 108. The skin was of a dirty lemon colour. The lymphatic glands in the axillæ and groins were palpable. The mucous membranes were very pale and the lips were blood-stained. Blood oozed continuously from the gums. The cardiac dulness extended above the third rib, to the right one centimetre beyond the sternal margin, and to the left three centimetres outside the nipple line. The first sound was loud and was accompanied at the apex by a rough murmur. A systolic murmur was also heard in the third interspace and was not transmitted to the vessels of the neck, over which a humming sound was heard. The pulmonary second sound was accentuated. Blood examination showed 20 per cent. of hæmoglobin and 970,000 red and 3600 white corpuscles per cubic millimetre. Blood was not found in the urine but was present in the fæces. The bleeding continued and the patient steadily lost ground. The diagnosis was obscure. Of hæmophilia there was no history. Scurvy was negatived by the absence of changes in the gums or intramuscular or subdermal effusions. The morphology of the blood excluded pernicious anæmia. On April 26th the patient seemed to be sinking rapidly. A large vein on the left elbow was anastomosed with his wife's left radial artery at 5 52 P.M. and transfusion was continued until 7.25 P.M. Both husband and wife stood the operation well. The red corpuscles at 5 50 P.M. were 420,000; at 7.15 P.M. they were 1,001,000. The bleeding from the gums almost ceased and the patient's colour improved. On the 28th he was much better and there was merely a trace of hæmorrhage from the gums. Transfusion was performed from the

Average date of onset 17·7 days.

decrease in irregularity with increase in the ages of the patients is clearly demonstrated in both—adults being almost exempt. The latter fact did not altogether escape Villy, since he adds "the number of adult patients is somewhat small to draw any certain conclusions from." This reservation is, however, quite unnecessary since my tables add additional testimony to the fact, as well as the experience of several hundred other cases. Neither the scarlet fever nor the diphtheria cases listed exhibited repiratory irregularity (with quiet breathing) in those over 25 years of age. The fact is plainly evident from these three tables that the particular variety of disease has got very little to do with the question, and a bald statement of percentage occurrence of irregular pulse in diphtheria might be said to point to nothing but the comparative numbers of patients at the different age-periods, and to be innocent of any serious cardiac implication.

This view of the case is in accord with the well-established fact that true irregularity of the pulse where myocarditis is in question must always be regarded as a very grave sign indeed. It points to the utter disbandment of the four "myogenic" forces of the heart wall. Towards the end of the first fortnight of diphtheria death usually takes place by sudden dilatation of the heart accompanied by delirium cordis. At this time these signs almost invariably point to a fatal ending. The irregularity here is unmistakeable in type—a staggering disorderly beat, completely independent of the respiratory act. As convalescence progresses the heart wall, however, shows itself more and more resistant to the forces of dissolution. Intermittence of the pulse is another sign which "seems to point to serious involvement of the myocardium."[9] It is a significant fact that its percentage occurrence is also a small one. Hibbard[8] gives 3 per cent. I have not found more than 4 per cent. in 800 cases. They are generally those of a severe type. In cases developing favourably intermittence usually disappears in a week or two. The fact that it does this and does not hang about for months and years like the spurious irregularity of the pulsus paradoxus points to the really serious import of the sign, which disappears with the repair of the myocardium. We can be sure that when intermittence and true irregularity of the pulse are present in diphtheria they are generally there on matters of grave import to the patient—to depart when the more serious aspect of the case has disappeared. Again, intermittence is generally regarded as the first beginnings of irregularity, the latter showing a more advanced stage of the cardiac disorder. Thus Broadbent[10] says, "Irregularity of cardiac action is more serious than intermission." Since then intermission occurs in only about 4 per cent. of cases it seems more than likely that a not much larger percentage can be claimed for true myocardial irregularity.

An attempt is generally made to state a period in the disease when the pulse becomes irregular and again a period when it may be expected to lose that quality. For instance, Bolton[7] speaks of the irregularity generally commencing in the second week, and Villy[3] goes so far as to estimate an average time of onset—17·7 days. This gives a serious aspect to what is really a harmless event capable of a very simple explanation. For it happens that in a case of moderate severity the temperature falls just about this time and along with it the pulse, which now enters the bradycardial stage so typical of this period of the disease. With the bradycardia comes the respiratory irregularity of the pulse; and not till then, because by the rule governing the appearance of respiratory irregularity the latter is not exhibited *in a relatively accelerated pulse, while relative* slowing increases the tendency to its occurrence. The latter fact Wenckebach[5] has noted in the following paragraph: "Winkler observed that when the frequency of the pulse is raised during mental exertion the difference in the period length is almost completely abolished, while it becomes very marked again during the rest after the mental work, as the pulse becomes correspondingly slower." I have known cases where the respiratory irregularity was so marked as to lead one to believe there was an admixture of true irregularity, develop a perfectly regular pulse in the acceleration due to a slight intercurrent tonsillitis. In contrast with this it will be remembered that acceleration of the pulse by vigorous exercise is used as a test to best bring out any suspected tendency to true myocardial irregularity. Here is an essential difference. We need not stay to discuss whether the former phenomenon is due to the acceleration of pulse or to the increased blood pressure accompanying it. The latter is no doubt the main consideration, and here Sir James Barr's explanation fits in very well; as do also Wenckebach's remarks about neurasthenia. For about the end of the first fortnight the typical case of diphtheria falls into a depression of subnormal temperature, slow pulse, and low blood pressure (the latter I have ascertained by proper instrumental measure*ments*).

Here, then, are the ideal conditions for the development of the pulsus paradoxus, and in probably no other disease are they more ideal. Consequently marked examples occur perhaps more often in diphtheria, although the phenomenon itself can hardly occur more frequently, seeing that the former is mostly a disease of children. Moreover, for reasons which would prove very interesting to discuss, in some of the worst cases of diphtheria, bradycardia is absent, the pulse-rate being well sustained. Here, where most irregularity of the pulse might be expected, none is found unless occasionally that of myocardial causation. Some may, however, still urge that the bradycardia and respiratory irregularity must have some relation to the severity of the attack, and therefore it may be maintained that this irregularity still furnishes a useful prognostic guide. There is a limited amount of truth in the first contention, but the bradycardia is always the more important prognostic indication, the patient on no account being allowed up till the tachycardial reaction is well established. Any respiratory irregularity still continuing at that time would be ignored. And in fact it is always a secondary matter and could be easily dispensed with as a prognostic sign, the exact cardiac condition being read from other much more reliable data. The tension of the pulse, for example, is, on the other hand, a sign of very real importance.

It might then be supposed that when the body draws out of the bradycardial depression and the tachycardial period supervenes respiratory irregularity of the pulse should disappear, but this is not the case. For there is a great range of pulse-rate at this time throughout the 24 hours, from 64 to 120 being not uncommonly met with in children. The pulse then tends to be regular at the period of greatest acceleration, with marked irregularity in the period of relative slowing. Now it has been the custom to attribute everything irregular in the behaviour of the pulse at this time to the influence of the vagus nerve, which has so often been found degenerated at this period. These alleged irregularities include: the *presence of irregular pulse*; the supposed irregular manner in which this irregularity comes and goes throughout the 24 hours; the marked changes or range of pulse-rate during the daily periods; and the frequent changes in the volume of the pulse. The first two have been explained by the effect of the change of rate where a tendency to the pulsus paradoxus is present. The change of rate itself does not, except occasionally, need the vagus influence to explain it, since it has often—though the connexion is not always clear—a basis on the daily movement of the temperature (or on some bodily state on which they both rest) which exhibits considerable daily spiking at this time, often rising above normal. A daily rise and fall of blood pressure is also more or less coincident with these. The changes in the volume of the pulse may also be explained by its usual relationships to alterations in the foregoing. One of the writers[7] mentioned above has again unwittingly furnished us with an illustration of the pulse at this period which is at the same time a into three groups: (1) the first concerns cases characterised by markedly exaggerated knee-jerks and anatomically by a degeneration of the posterior columns in the thoracic region and a recent degeneration of the pyramidal bundles; (2) in the second group the knee-jerks are abolished, which corresponds to a considerable degeneration of the posterior columns in the lumbar regions and some degeneration of the pyramidal tracts; and (3) in the third group there is a marked degeneration of the posterior columns throughout the entire cord, and, again, some changes in the pyramidal bundles. Dr. Gordon concludes from these studies that although "the motor pathway is always involved nevertheless it is only to a very slight degree in the majority of cases." As Babinski's sign is usually the clinical expression of a well-defined degenerative lesion of the motor tract the very moderate degree of pyramidal involvement will perhaps satisfactorily explain the rarity of the "phénomène des orteils" in paresis. He goes on to state that, "on the other hand, the study of the paradoxical reflex in organic nervous diseases suggests very strongly that it is the expression of a slight or early involvement of the motor tract." He found that in 60 cases of well-developed general paralysis which he examined the paradoxical reflex was present in 42 instances and that in 39 of these the knee-jerks were increased and absent in the remaining three. The Babinski sign was present on both sides in only three of the cases and in four others on one side only. Further, he found that in all except two cases when the Babinski sign was present the paradoxical reflex was absent and *vice versâ*. He then passes on to consider Oppenheim's reflex in relation to the Babinski sign and the paradoxical reflex in general paralysis and finally sums up his conclusions as follows: "the old triad of reflex phenomena—viz., exaggerated knee-jerks, ankle-clonus, and Bakinski's sign—which we are accustomed to find in hemiplegia, or in any other organic disease with a distinct degenerative lesion in the motor pathway, is here markedly dissociated. While the first is present in the majority of my cases, the other two are rare. Of the two more recently described reflexes, Oppenheim's is also rare, while the paradoxical is frequent."

THE "GOUTTES DE LAIT" INTERNATIONAL CONGRESS AT BRUSSELS.

THE Second International Congress of Gouttes de Lait is being held in Brussels from Sept. 12th to 16th inclusive, the first Congress having been held in Paris in October, 1905. The work of these congresses may be summarised under three headings: First, to give advice to mothers; secondly, to encourage breast feeding; and thirdly, to distribute milk to those infants for whom breast-feeding is either impossible or insufficient. The present Congress is divided into two sections, the first concerned with social and philanthropic questions and the second with the problems of infant hygiene. Foreign delegates may address the Congress in their own language and interpreters are attached to the sections. The main question to be discussed at the general meeting is as follows: "Is it advisable to widen the scope of the congresses of 'Gouttes de Lait' so as to include in their programmes all questions relating to the protection of child life, and should forthcoming congresses bear a new name which will denote the change?" In section 1 the following questions and subjects are to be considered:—

1. Are the "Gouttes de Lait" and other institutions for the protection of infant life satisfactory means for the prevention of tuberculosis, and can they be considered as forming the first necessary step in the solution of the problem of the prevention of tuberculosis? 2. An account of the legislation of different countries concerning the control of the production and distribution of milk. Special stress will be laid in the papers on the measures taken in certain towns for the control of infants' milk. 3. (*a*) Description of institutions of different countries for the prevention of infantile mortality. (*b*) Exact statistics of infantile mortality in each country.

In the second section the following matters are to be discussed:—

4. (*a*) The regulation of infant feeding: (1) breast feeding; (2) artificial feeding. (*b*) Study of digestion in infancy (glandular appendages of the alimentary canal, intestinal flora, fæces, &c.). 5. (*a*) The different milks used in artificial feeding, and the indications for their use. (*b*) Practical and rapid clinical methods of analysing milks. 6. Instruction in the hygiene of infancy by official and private agencies, and its popularisation in different countries.

The Congress is held under the patronage of their Royal Highnesses the Prince and Princess Albert of Belgium, and the general secretary of the Congress is Dr. Eugene Lust, Rue de la Limite, 27, Brussels.

THE ROYAL SOCIETY OF MEDICINE: CLINICAL SECTION.

THE meetings of the Clinical Section of the Royal Society of Medicine will, during the coming session, be conducted on lines somewhat modified from those of its predecessor the Clinical Society of London. It is proposed that during the first half of each meeting medical and surgical cases shall be exhibited and that the remainder of the meeting shall be devoted to the reading of papers. The latter will deal exclusively with the records of cases and clinical methods. The number of meetings during the session has been reduced to eight, and the first meeting will be held on Friday, Oct. 11th.

THE PRODUCTION OF ŒDEMA.

THE question as to the mechanism by which the œdema characteristic of cardiac failure and of renal disease is produced is among the most interesting problems of pathology and distinguished workers have given varying answers to it. Thus Heidenhain, who found that certain substances such as leech extract were capable of causing the escape of lymph from the vessels into the surrounding tissue, inferred that formation of lymph was due to a secretory action of the cells in the capillary walls and that dropsy was caused by overaction of these cells. Professor E. H. Starling, as the outcome of very ingenious experiments, threw doubt on this vital action. He found that by injecting into the blood harmless crystalloid bodies such as glucose it was possible to produce an inflow of lymph into the blood-vessels, resulting in a condition of hydræmic plethora or increase in the total amount of blood with diminution in its density. Œdema, he held, was caused by the resulting rise of pressure in the capillaries, assisted by changes in their walls. He endeavoured to bring the phenomena of cardiac dropsy into line with these observations by assuming a similar inflow of lymph to take place as the result of diminished pressure in the veins. This diminution of pressure was inferred to exist from the observation that obstruction of one of the large veins, though producing a rise of venous pressure near the heart, was accompanied by a shrinking in bulk of the limbs as shown by a plethysmograph—a phenomenon attributed to a fall in vascular tension. Dr. Charles Bolton has recently, in a communication read before the Royal Society on Jan. 17th, come forward to break a lance with Professor Starling over the reality of the condition of hydræmic plethora in such cases. He disputes the accuracy of the inference on which it is founded, as he finds that the result of obstructing one of the venæ cavæ is to produce a transitory rise of pressure in the veins of the limbs which quickly falls to normal owing to a compensatory dilatation of communicating channels, and that the œdema occurs at a time when there is normal venous, and either normal or diminished arterial, pressure. Hence in his view the escape of lymph which constitutes œdema is not due either to increased pressure in the capillaries or to hydræmic plethora. He attributes it to alteration in the capillary walls, though the exact cause of this alteration is not clear kinked and subacutely inflamed, with some peritonitis around; the gastric ulceration remained unsuspected until the post-mortem examination.

(2) A female, aged 27 years, died four days after operation for acute gangrenous appendicitis with peritonitis and tympanites, the acute symptoms having set in about 24 hours before operation. At the post-mortem examination the lower half of the abdomen and wound appeared to be healing satisfactorily. The stomach showed the remains of wide-spread gastric ulceration and the upper small intestines were much dilated. She had suffered from dyspepsia for 10 years and had been accustomed to take enormous quantities of commercial bicarbonate of soda.

(3) A man, aged 35 years, was seized with abdominal pain and diarrhœa. His stools came to contain large quantities of blood; later they mainly consisted of pus. He rapidly wasted, suffered from aphthæ, and died in the sixth week of the illness. On the fourteenth day he had commenced to have pains in the ileo-cæcal region; on the eighteenth day he was operated upon and an acutely inflamed appendix was found bound down by old adhesions and there was local septic peritonitis. After the removal of the appendix all peritoneal symptoms ceased and the wound healed well. The diagnosis of the intestinal affection proved impossible, as a post-mortem examination was refused; it was supposed to be a case of ulcerative colitis, but there was no fibrin or mucus in the stools and the course was rapid. All the reactions of typhoid fever were negative; there were no fever and no leucocytosis except in connexion with the intercurrent appendicitis. There was no evidence of any leaking abscess.

Probably none of the foregoing three cases would have died from the appendicitis alone.

(4) A female, aged 20 years, had acute gangrenous appendicitis with peritonitis, which had commenced five days before, and there was already marked tympanites. She died about 24 hours after operation and was found to have been otherwise healthy.

CLASS III.—Cases of suppurating appendicitis treated by shelling out of the appendix, wiping out the affected portion of the peritoneal cavity, and afterwards filling it with gauze; some cases were partly sutured. 14 cases; one death. No sinuses persisted, for the appendix was in all completely removed up to and including its funnel-like junction with the cæcum. Owing to slow healing some of the scars were not at first firm and several of the cases have been ordered belts. Possibly a case may require excision of the scar and suture in stages.

Of the death:

(5) A female, aged four years, after eight days of obscure abdominal disturbance, had marked tympanites. I found a multiloculated abscess in the pelvis around a gangrenous appendix. The child died 38 hours after operation.

CLASS IV.—Cases requiring an extensive ileo-lumbar incision for the removal of the appendix and the complete evacuation of pus and fibrinous masses. All the suppurating cavity was packed with gauze whilst pushing back the intestines. Secondary suture was done as soon as granulations lined the cavity. 18 cases; two deaths. All the scars remain sound and no belts or trusses have been required. The earliest secondary suture was four days after operation, the average being about nine days after. In one case in which a portion of the cæcum was already gangrenous, and a free fæcal fistula followed, the parts around were so soft that it was only after four months that the secondary suture could be undertaken, when a careful dissection and suture in stages resulted in sound healing. In another case a sinus persisted after the secondary suture. Six months later I explored to find that the sinus ran upwards through the psoas muscle nearly to the spine. A thorough scraping was followed by sound healing. In one case I made this deviation from the rule of always excising the appendix; I had already completely exposed the area of suppuration, and isolated the cæcum and appendix when the patient's condition appeared dangerous, so I wrapped up the cæcum and appendix in iodoform gauze. Three days later I removed the appendix and sewed up except for a drain.

Of the deaths:

(6) A male, aged 20 years, was seized with an obscure abdominal attack immediately after a long bicycle ride, during which his pulse and temperature, after being at first raised, became normal and the temperature even subnormal. He was found to have an abdominal abscess extending from the pelvis upwards in front of the intestines, and pus came out from the foramen of Winslow; the tip of the appendix had sloughed off and there were two concretions loose in the pelvis. On the second day after operation a portion of the cæcum sloughed. After a month an attempt at secondary suture was made and failed. In the second month after operation he passed pus in his motions and septic bronchitis appeared. In the third month a left empyema had to be drained. He died ten weeks after operation. There was suppuration between the diaphragm and the liver and spleen, also in the lesser peritoneal cavity, and multiple abscesses in both lungs. The method of operating here failed because the suppuration had already extended upwards into the lesser peritoneal cavity. The pus throughout showed streptococci.

(7) A male, aged 19 years, had acute gangrenous appendicitis with septic peritonitis, followed by tympanites. He was brought in collapsed and covered with a cold sweat. The appendix had sloughed owing to two concretions; the pelvis was full of pus and fibrin with adhesions. He died six hours later. There was no post-mortem examination.

Thus it has been possible to diagnose and to operate on 100 cases of appendicitis, with a loss when the appendicitis was the sole disease of only four, a result which removes the various objections that have been raised to the method.

Brook-street, W.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ACUTE ARTHRITIS COMPLICATING A CASE OF OPHTHALMIA NEONATORUM.

BY J. H. F. NUNN, M.R.C.S. ENG., L.R.C.P. LOND.

MRS. ——, a healthy primipara, gave birth to a strong, well-nourished child. On the third or fourth day after birth an acute attack of purulent ophthalmia of the infant's left eye developed. The conjunctivitis was treated with boric and perchloride of mercury lotions and occasional applications of silver nitrate paint (10 grains to one ounce) as the discharge was profuse. Care was taken to allow the child time for sleep. About 24 hours after the conjunctivitis of the infant declared itself the mother developed an attack of pelvic inflammation. I obtained a distinct history of gonorrhœa from the father of the child, who had been treated for the complaint, and I ascertained from the mother that she had had a discharge for some weeks previous to her confinement. After four or five days, when I hoped that the infant's right eye had been preserved, it became similarly affected to the left which was now almost well. At this juncture the metatarso-phalangeal joint of the left great toe of the baby became hot, swollen, red, and painful to touch, the condition being similar to a comparatively mild attack of gout. The nurse was careful and from her I could obtain no evidence of a fall, bruise, burn, or any injury likely to produce the condition. The joint became slightly better, but on the left eye becoming reinfected (this time the condition was worse than before, so that a large central opacity developed which eventually nearly disappeared) the joint again became more acutely inflamed. The arthritis gradually subsided without leaving any stiffness or trace of the inflammation. The child's digestion and bowels were attended to and the joint was occasionally fomented and protected with cotton wool, beyond which no treatment was attempted. The reduction of the discharge from the eye by the use of silver nitrate appeared to coincide with an improvement in the joint, and when the paint was not used for 36 hours there was not only an increase in discharge from the eye but also in the swelling of the joint.

Judging from the usual course of gonorrhœal arthritis, and from the fact that the child was healthy and its strength was being maintained, and that the apparent cause was being treated and thereby diminished, I considered the prognosis to be favourable.

I mention the case because the complication was unexpected, and an ophthalmic surgeon of experience could not recall a similar occurrence; neither had I during 15

NOTES UPON HEALTH RESORTS.

SOME MEMORANDA ON THE ITALIAN LAKES.

BY H. B. T. SYMONS, L.R.C.P. IREL., &c.

THE Lakes of Lombardy, with the adjacent and mainly Swiss Lake of Lugano, probably form the chief intermediate climatic station in Europe. An annual convergence of visitors arrives from north, south, east, and west, or, to speak more precisely, there are two such convergences—one at the end of winter and one at the end of summer. It is therefore not remarkable that, in view of the increase of travel, sojourners in this region should have multiplied 100 per cent. during the past decade. It is possible, then, to reach the lakes from the four cardinal points of the compass. To those arriving from Great Britain—they can do so in a day's travel—Lake Maggiore is first attained. The greater number of travellers go on, in the first case, to Como. The favourite months are May and September. In the spring the weather, when fine, is unsurpassable; when it is bad, and the spring is the most rainy season, it is extremely so. Viewed in this light the autumn, being drier, is preferable. Como for the climatologist presents no special indications as to locality. The centre of lakeland is called the basin of Tremezzina, where the lake bifurcates Y-like. Places on the right bank have more sun. At random I specify one on either side of the lake, and in different localities of the lake, which are well adapted to the health-seeker's wants. Steamers afford ready and pleasant means of connexion between places to be visited.

First in order of these the Villa Serbelloni may be mentioned. It crowns the promontory of Bellagio, the centre of the "Y." It is possibly the oldest inhabited place on the lake whose records have been preserved, and I incline to think that it is still the most beautiful. Once a stronghold and afterwards a villa, it is now a hotel not over-frequented, select, but expensive. The grounds are magnificent. There is an English colony at Cadenabbia opposite on the left shore of the lake. The second of these places is the Villa d'Este, Cernobbio, which was formerly the residence of Queen Caroline during her voluntary exile from England in the early part of the nineteenth century. This spacious house seemed to be for a long time infected with a gloomy dignity to which modern hotel methods have now succeeded.

The journey between Lake Como and Lake Lugano may be made by rail at either end or in the middle from Argegno on Como to Osteno. If the last route be taken a sharp ascent of some 2000 feet has to be climbed, through the Val d'Intelvi. At the head of the valley is Lanzo d'Intelvi, a growing resort suitable for early summer and autumn in the main. In view of its moderate elevation, 3000 feet, it has attractions to those desiring to pass the summer in the locality of the lakes and to avoid excessive altitude. The nights are fresh and its position on the mountain side looking northward to the Bernese Oberland is such as to render it cooler than many places of similar elevation.

A new funicular railway has just been opened from Lanzo to Osteno. The approach from Lugano will thus be much facilitated, which town one passes through in retracing the way to Lake Maggiore. On Lake Maggiore there are two places that have been praised for the climate to be found there, Pallanza and Locarno, both looking full south. The former has mostly German visitors and the chief hotel is arranged according to Teutonic ideas of comfort. A thick coppice of yew trees surrounds the building. Locarno presents surroundings of a markedly pleasing character. The contour of the hills at the lake-head makes for all that is delightful in alpine form and colour. To my mind the place is rather over-rated climatically. As a specimen of the statements which pass from book to book so much in matters of climate without challenge one finds those on Locarno apt to be specially fallacious; it is commonly credited with furnishing an all but tropical climate. Even such writers as Dr. I. Burney Yeo and Mr. R. Bagot, the well-known writer on Italian subjects, have been somehow misled on this point. "During the winter months," says Mr. Bagot in a recently published work on the lakes, "Locarno possesses a climate superior to the French or Italian Riviera; orange and lemon-trees abound, myrtle and many other semi-tropical shrubs and plants flourish throughout the winter." Locarno is an admirable place in the late autumn, for at this season the weather is sunny here if anywhere and society is to be found in this locality when Bellagio, Menaggio, Baveno, or Stresa present a deserted air. With the close of the autumn, however, the orange-tree, "that busy plant," as George Herbert has described it, is ingeniously housed, and the semi-tropical shrubs receive their winter clothing of heavy matting, the whilom semi-tropical garden disappears, and the illusions of perpetual summer flee away. A large colony of people practising the "Nature Cure" live here. Lake Orta, smaller and rather remotely placed, and Varese, near Como, should also be mentioned.

Briefly, the Italian lakes, amongst other considerations, may be described as the convalescent's paradise. The moderate elevation, the extreme equality of temperature, the freedom from dust and noise, the picturesque surroundings, and the pleasant variation of the scene easily obtained afford conditions admirable for mind and body undergoing restoration. Under this heading one may place the "after-cure" for bathers or Weir-Mitchell patients. Early *poitrinaires* are in some instances benefited, or at least it is believed that they may stay here without harm. Whether hotel life be appropriate in pulmonary tuberculosis is a question which must be left to the consideration of others.

MEDICINE AND THE LAW.

An Illicit Still and an Absurd Story.

THE explanation recently put forward in a prosecution for unlawfully manufacturing spirits and using an illicit still drew from the magistrate at Marlborough-street police court some trenchant observations upon the absurdity of wasting his time with stories that might amuse but could not deceive him. The defendant, a Russian butter and cheese maker, named Jacobovitch, had on his premises a still and about 40 gallons of wash in an active state of fermentation, and explained to the inland revenue officials who discovered them that the wash was a kind of sauce, and that the still was used for cheese-making by passing a hot pipe through the milk. Variants of this story were put forward at the police court and witnesses were called to swear that the defendant's only business consisted in manufacturing cheese or butter. As Mr. Denman observed: "There is no limit to what these people believe to be the gullibility of the magistrates before whom they come." As a matter of fact, in these important prosecutions, which not only defend the rights of the revenue but protect the public from being poisoned with unwholesome spirits, and in those others which seek to prevent the distribution of putrid or adulterated food, there is always some story easy to be invented if only a magistrate can be found to lend an ear to it. It will, for instance, have been observed that a large proportion of the retailers of foodstuffs, who from time to time are prosecuted for offering for sale articles of obviously human diet in an unfit condition, promptly discover that they have bought sacksful of tins of preserved milk or large quantities of putrid fish or meat in order to sell it for feeding pigs or for manuring the ground Those operations are extremely unlikely to be carried out in the manner that the defendant's story suggests, but presumably it satisfies his fighting spirit and he feels that he has not submitted to be fined or imprisoned without a struggle. Mr. Denman professed himself to be amused at the ingenuity of Jacobovitch (who on a previous occasion had been fined £25 for a like offence), but he fined him £125 nevertheless, with the alternative of four months' imprisonment. If the law were only concerned in "making the punishment fit the crime" the better course, and one which perhaps might have been adopted in an Oriental country, would have been to sentence him to imprisonment together with his still and his 40 gallons of wash until he produced a palatable condiment or a few pounds of either cheese or butter by the novel processes of manufacture of which he claimed to be the master.

Street Noises.

A coal hawker and an oilman were recently summoned before Mr. Plowden at the Marylebone police court on account of the noise made by the former in shouting "coal" in a certain street at 11 A.M. and by the latter in calling attention to his wares by ringing a bell. The learned magistrate appears to have had little sympathy with the desire of the complainants, who were the police at a neighbouring section house, to sleep after their nights on duty, for he

Reviews and Notices of Books.

Diseases of the Eye: A Manual for Students and Practitioners. By J. HERBERT PARSONS, D.Sc., M.B., B.S. Lond., F.R.C.S. Eng., Assistant Ophthalmic Surgeon, University College Hospital; Assistant Surgeon, Royal London (Moorfields) Ophthalmic Hospital. With 15 coloured plates and 308 woodcuts. London: J. and A. Churchill. 1907. Pp. 664. Price 10*s.* 6*d.* net.

IT is difficult for the most original of authors to present to his readers any great novelty in the mode of discussing the subjects that must be dealt with in a manual of ophthalmology intended for the use of the large classes of senior students and of junior practitioners; for it is only the student in the last year or two of his attendance in the wards of a hospital or the young practitioner in the first year or two of his professional work who has the time or the inclination to master the details of so large and important a subject as the diseases of the eye. Yet there are few departments of medicine the study of which is more interesting, owing to its numerous relations with other branches of science, or which, when successfully pursued and applied, is more useful to man. The author of this work has excellent qualifications for the office of a teacher. He is connected with a special hospital presenting the most extensive field of observation of diseases of the eye in England. As curator of the museum at Moorfields he has large opportunity of examining the exceptional as well as the more common diseases of the eye. And the works which he has already published on the pathology and on the physiology of that organ show that he has not neglected opportunities which have now enabled him to produce one of the most useful manuals to be found in any language.

In recommending the volume to the junior members of the profession we may remark generally that it is of handy size, clear print, and that it possesses excellent illustrations, those in particular showing the macroscopic changes in the iris and retina, many of which are coloured, being exceptionally instructive. Finally the space accorded to each division of ophthalmology is fairly in accordance with its importance to the learner. In the plan of the work the arrangement in chapters or divisions is—anatomy and physiology, examination of the eye, the diseases in topographical order, errors of refraction, disorders of motility of the eye, diseases of the adnexa of the eye, and some appendices specifying the requirements of the public services.

As might be expected from Mr. Parsons's familiarity with pathological researches, this aspect of the diseases of the eye is brought into prominence to the great advantage of the student, since much of our knowledge of the intimate changes taking place in inflammation of opaque tissues is derived from the investigation of the processes occurring in the transparent tissue of the cornea. We are tempted to transcribe the account, or rather a part of the account, of the process of ulceration in the cornea to show the mode in which accurate pathological knowledge is brought to bear by Mr. Parsons not only on the limited area of the cornea but upon inflammatory affections generally. After describing the usual form of an ulcer in the progressive stage as saucer-shaped with walls thickened from imbibition of fluid and the presence of numerous leucocytes, he points out that a line of demarcation is formed as in necrosis elsewhere. The toxins are most concentrated near the centre where the organisms are most numerous but dead owing to their virulence. Then, as Leber showed, a ring or wall of leucocytes containing many nuclei forms a second line of defence. Here the leucocytes are neither paralysed nor killed by toxins but are able to exert their digestive functions, removing by dissolving or digesting the necrotic tissues. The process of reparation is then described and with vascularisation the regressive stage is reached, the stages of which are given. But in certain circumstances some of the toxins elaborated by the bacteria diffuse through the cornea into the anterior chamber, where they exert an irritative effect upon the vessels of the iris and ciliary body, causing hyperæmia of the iris, and in severe cases the formation and discharge into the aqueous from the vessels of numerous leucocytes which gravitate to the bottom of the anterior chamber where they form an hypopyon. "There are several important facts about hypopyon," Mr. Parsons continues, "which must be borne in mind. The pus cells do not come from the cornea as was once thought. This is proved by the following facts: 1. Descemet's membrane is impermeable to leucocytes though fluids pass readily through it. 2. The cells sometimes contain pigment granules obviously derived from the uveal tract. 3. If the ulcer have not perforated the hypopyon is sterile. The last fact is of the very greatest importance both theoretically and practically. It shows that the leucocytosis is due to toxins, not to actual invasion of bacteria which indeed are as incapable of passing through the intact Descemet's membrane as are leucocytes. It accounts for the ease and rapidity with which hypopyon is often absorbed; it may develop in an hour or two, rapidly disappear, and as readily reappear. Such hypopyons are very fluid, always moving to the lowest part of the anterior chamber if the position of the patient's head be changed. The fact that the hypopyon is sterile has great practical importance—it is unnecessary to remove the pus as is the rule in all other parts of the body; if the ulcerative process can be stopped the hypopyon will be absorbed." Of course in exceptional cases its removal becomes necessary.

Cataract and the operations for its removal are described succinctly but in quite sufficient detail for the junior practitioner. As a matter of fact, the cases requiring extraction of the lens do not in general fall to his lot. To be successful the diagnosis must be satisfactorily made and the surgeon must know the steps of the operation and must not only have the appropriate instruments but they must be in perfect order, a blunt point to the Graefe's knife often leading to undue pressure upon the globe and loss of vitreous. Mr. Parsons confines himself in the diagnosis of errors of refraction to the employment of the shadow test, yet the application of this test can hardly be learnt from books except in the dark room of a hospital with an expert at hand to explain the difficulties which so often arise and which often prove puzzling even to him. We have seen several cases excellently determined by the late Mr. Hulke by the "slit" test alone and this method might have been given as an alternative and certainly much easier method than skiascopy.

The chapter on Sympathetic Ophthalmia is written in accordance with the lights of the present day, but supplies sufficient evidence that this is still a dark corner of ophthalmology and affords little help to the general practitioner who is suddenly confronted with a wound in the globe and has to determine whether he should attempt to apply the ordinary rules of surgery or at once proceed to its removal. The fact is, that we require many more clinical histories of carefully observed cases, supported by such pathological details as Mr. Parsons, Mr. E. Treacher Collins, and other expert microscopists can supply. We want to know why a prick with the point of a pin is followed in one case by no more than a trifling local inflammation and in another apparently exactly similar by the most disastrous results, not only to the injured eye alone but to the opposite one. We want to know better than we do at present the means or channels by which the evil influence is conveyed from the excitor to the sympathising eye, and, above all, we want to know the treatment that should be adopted at the early and at the later stages of the affection, the grounds inducing us to preserve the injured eye in one drain the fruit-pickers' huts. The subject of infantile mortality in this district has been gone into very thoroughly by the medical officer of health during the past year, more especially as regards the eight years during which he has been in office. In this way he has been able to procure averages having a much higher value than the rates for one year would possess. The average infantile mortality for the eight years in question was 132 per 1000 births, the legitimate rate being 124 and the illegitimate 404; while one of the special tables constructed by Dr. Richmond shows that 19 per cent. of the deaths occur under the age of one week, 31 per cent. under one month, and one-half under three months, the remainder being fairly evenly distributed over the remaining months. Of the total deaths under one year of age 37·5 per cent. were due to wasting diseases and 23 per cent. to diarrhœal diseases; while of the total deaths under one month no less than 74·2 per cent. were due to wasting diseases. This group of wasting diseases may be divided into two sub-groups, premature birth and atrophy, and of those due to premature birth 60·5 per cent. of the whole occur immediately on birth or within the first week. Dr. Richmond thinks that the medical officer of health can do very little to check mortality under this head. As regards, however, the second sub-group—i.e., atrophy and like causes—there are many which occur in the first week which are probably due to pre-natal causes. These deaths diminish for the next three weeks but increase in the second and third months, and at this time the causes are post-natal and preventable—i.e., due to neglect, artificial feeding, and insanitary surroundings. By way of curtailing the death-roll under this head Dr. Richmond proposes the appointment of lady visitors who should visit and instruct the mothers as to the proper methods of feeding their children and who should report to the sanitary officials any defects in the sanitary condition of the houses. We much hope that this suggestion will be acted upon, and there is no reason why visitors of this description should be appointed in urban districts only. We should be glad, too, to see this subject of infantile mortality analysed as carefully in other rural districts as in the Dartford district, and it is gratifying to find a rural medical officer of health gratuitously going beyond the already very complicated tables which he is bound to fill up.

County Borough of Bournemouth.—Mr. P. W. G. Nunn, the medical officer of health of this important health resort, condemns in his current annual report the belief that pulmonary tuberculosis possesses the high degree of infectivity with which it is credited by some persons. His experience at Bournemouth during 36 years has not tended in this direction and in his view had the disease possessed this attribute the low death-rate attained by Bournemouth would not have been achieved. Certainly the evidence of Bournemouth, with its numerous institutions for pulmonary tuberculosis, should be of value, and we wish that Mr. Nunn had entered a little more into detail upon his subject. There is, however, much evidence from other places pointing to the conclusion that the presence of sanatoriums and hospitals for consumption exercises no prejudicial influence upon the death-rate from this disease; indeed, in the majority of such places such death-rate has steadily declined. The borough analyst, whose report is bound up with that of the medical officer of health, reports that one sample of milk contained no less than 35 grains of boric acid to the pint, a somewhat drastic dose to administer to invalids or children without their consent or knowledge. We are glad, therefore, to see that the town council has decided to take action in all cases where 40 grains to the gallon of boric acid and formalin to an amount exceeding one part in 40,000 are detected.

Reigate Rural District.—Provisional arrangements have apparently been made between the medical officer to the education committee of the Surrey county council and the local medical officers of health by means of which a closer supervision over the health of the scholars may be maintained than heretofore. The school teachers are now required to notify to the local medical officer of health whenever a child is absent from school owing to any infectious or contagious malady or when there is even a suspicion of such an occurrence. The medical officers of health are, too, expected to visit each school at least once a year and to examine into its sanitary conditions. The examinations made in this sense in 1906 by Dr. Arthur E. Porter seem to indicate that in several instances the local schools ought not to be used as such. We read of "sanitary conveniences badly situated," "no water supply to urinal," "very poor cloakroom accommodation," "not a suitable building for a school," and "quite unfit for a school." If these statements are not out of proportion they should receive the immediate attention of the education authority.

County Borough of Salford.—Mr. C. H. Tattersall's current volume embodies a report by Dr. J. J. Butterworth, the deputy medical officer of health and assistant medical officer to the education committee, upon the medical inspection of schools. The routine practice appears to be to visit the schools regularly and to inspect the children rapidly. All those suffering from physical or mental defects are noted. If as a result of further examination of these selected children it is found that medical treatment is desirable, apart from some modification of school attendance, the parents are advised either to consult a private practitioner or to attend at hospital with the child. In addition to this method of determining defective children it is within the province of the school attendance officers to refer children to the medical inspector. The physical instruction sub committee undertook in 1904 to have the measurements of boys taken in six elementary schools and some useful data, not in a form which can be conveniently epitomised, will be found in Mr. Tattersall's report. It may, however, be stated generally that the results as regards height were below the Edinburgh and Glasgow data, below the Anthropometric Committee average standard, and markedly below the public schools standard. Very similar observations obtain as regards weight. Apparently the Salford education authority supplies spectacles at a low and uniform price to children requiring them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 7980 births and 3785 deaths were registered during the week ending Sept. 7th. The annual rate of mortality in these towns, which had been equal to 11·5 and 11·8 per 1000 in the two previous weeks, further rose last week to 12·3 per 1000 During the first ten weeks of the current quarter the death-rate in these towns has averaged 12·0 per 1000, the rate in London during the same period being 11·9 per 1000 The lowest death-rates in the 76 towns last week were 3·1 in Wallasey, 5·4 in Walthamstow, 5·7 in East Ham, and 7·0 in Hornsey; the highest rates were 17·0 in Nottingham and in Liverpool, 17·2 in Tynemouth, 17·6 in Newcastle-on-Tyne, and 19·7 in Stockton-on-Tees. The 3785 deaths in the 76 towns last week exceeded by 168 the number in the previous week, and included 471 which were referred to the principal epidemic diseases, against 407, 432, and 437 in the three preceding weeks; of these, 229 resulted from diarrhœa, 80 from whooping-cough, 71 from measles, 39 from diphtheria, 34 from scarlet fever, and 18 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Willesden, Plymouth, South Shields, Huddersfield, Hornsey, Rochdale, or in six other of the 76 towns; the death-rates from these diseases, however, ranged upwards to 3·6 in Cardiff, 3·8 in Aston Manor and in Sheffield, 3·9 in Bootle, and 4·9 in Walsall. The fatal cases of diarrhœa, which had risen from 39 to 194 in the eight preceding weeks, further increased to 229 in the week under notice, and caused death-rates ranging upwards to 2·2 in Walsall, 2·6 in Rotherham, 2·9 in Sheffield, and 3·1 in Bootle. The deaths from whooping-cough, which had been 99 and 76 in the two previous weeks, rose again to 80 last week; the highest death-rates from this disease were 1·3 in Aston Manor and 1·4 in West Hartlepool. The fatal cases of measles, which had been 102, 84, and 73 in the three preceding weeks, further declined to 71 in the week under notice; the mortality from this disease was equal to 1·2 per 1000 in Blackburn, 1·4 in Merthyr Tydfil, 2·2 in Walsall, and 3·3 in Cardiff. The deaths from diphtheria slightly exceeded the number in the previous week, while those from scarlet fever and from "fever" showed a slight decline; the mortality from these diseases was not excessive in any of the 76 towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals and the London Fever Hospital on Sept. 7th was 3816, the numbers having risen successively in the 17 preceding weeks from 2658 to 3738; 587 new cases were admitted during the week, against 430, 440, and 557 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory system, which has been extensively adopted in America, but many authorities in this country do not view it with favour.

We do not think that this work adds much to the knowledge of hay fever, but it contains a good summary of the various opinions which are held in regard to the pathology and the treatment of the disease.

Operative Gynecology. By HOWARD A. KELLY, A.B., M.D., LL.D., F.R.C.S. Edin. (Hon.), Professor of Gynæcological Surgery in the Johns Hopkins University and Gynæcologist in the Johns Hopkins Hospital, Baltimore. Second edition, revised and enlarged. With 11 plates and 703 original illustrations. London: Sidney Appleton. 1906. Vol. I., p. 680. Vol. II., pp. 656. Price £3 3s. net for two volumes.

SINCE the first appearance of Professor Kelly's important work on Operative Gynecology nine years ago many important changes have taken place in this field of surgery. The very high place which this book has always occupied in gynæcological literature renders the appearance of a second edition a matter of much importance. The author has taken the opportunity of adding several chapters on various subjects of minor gynæcology so as to render the book more suitable for the general practitioner. For our part we somewhat regret that Professor Kelly has not been content to retain the special character of his work as one adapted particularly to the needs of the operating gynæcologist. There are so many subjects of interest only to the specialist on which we could hardly have too much written by so great an authority that we are sorry to see any space taken up by matters which are quite adequately dealt with in the ordinary text-book. The book, however, retains all its distinctive qualities, and the second edition, like the first, need fear no rivals in its own particular sphere. A very thorough revision has been carried out and in several instances chapters have been entirely rewritten.

In the first volume we notice a new chapter on bacteriology by Dr. W. W. Ford and one on the use of the x rays in detecting calculi by Dr. F. H. Baetjer. In the chapter on gynæcological examinations a new instrument, the piezometer, for measuring the resistance of the abdominal muscles present and for determining indirectly the amount of pain, is described. The method recommended of examining virgins in the knee-chest position with a long cylindrical speculum is worthy of attention. There are new chapters on local and palliative treatment, menstruation and its anomalies, and uterine displacements and their treatment by pessaries. The chapter on anæsthesia has been contributed by Dr. H. W. Cook. The subject of spinal anæsthesia is dismissed in a few lines and evidently meets with no favour in Professor Kelly's clinic, being described as unsatisfactory and unsafe. The section on Bartholin's glands has been considerably added to and there are several very good new drawings. The minute anatomy of the gland, based on Dr. T. S. Cullen's recent work, is very fully described and illustrated. In the chapter on relaxed vaginal outlet an account has been added of the operation devised by Dr. G. R. Holden for the purpose of uniting the anterior edges of the levator ani muscles and this is illustrated with several good figures. It certainly promises to be of value in these cases. Nearly 60 pages of this volume are given up to affections of the ureters, and we need not say that this chapter, embodying as it does so much of the author's special work, is one of the greatest interest and value. There are some very striking illustrations of wax-tipped catheters actually scratched by calculi. The chapter on inversion of the uterus, revised by Dr. Dobbin, is not up to the standard of the others, while the chapter on vaginal extirpation of submucous myomata and polypi is an interesting illustration of the fact that the one weak point in this work is to be found in the description of some of the simpler operations undertaken by the vagina. For example, here we actually see an illustration of the use of an écraseur; we are told to incise the cervix laterally in order to expose an intra-uterine fibroid, and ligature of the pedicle of a fibroid or mucous polypus is advised before removing either of these tumours. Although mucous polypi are said correctly to be often associated with a hypertrophic endometritis, no mention is made of the best method of treating them—namely, by curettage.

In the second volume the chapter on the general principles common to abdominal operations has been largely rewritten and there is a good illustration of the method of postural drainage which is often so useful and which consists in elevating the body to an angle of about 30 degrees to encourage the flow of all fluids to the floor of the pelvis. One of the most important chapters in the whole work is that on hysterectomy, with extirpation of ovaries and tubes. It has been extensively revised and a very good description is given of the author's method of bisecting the uterus as a preliminary to the removal of densely adherent appendages. The method is one which we have found of the utmost value in some of these difficult cases, and we can fully corroborate the advantages which are claimed for it. It turns what is often a most difficult and dangerous operation into one of comparative ease. The most interesting and the most helpful section of all we have always regarded as that on myomectomy and hysteromyomectomy. In this new edition there are some noteworthy additions and a number of new figures in this chapter. Further illustrations of the difficulties and dangers which may be encountered in dealing with complicated cases of fibroid tumours are given and the recital of the different devices adopted by the author in treating such cases cannot fail to be of the utmost help to all who have to deal with them.

At the present time we naturally turn with much expectation to the chapter on the operative treatment of carcinoma of the uterus. The whole has been revised and practically rewritten by Dr. J. A. Sampson. It is one of the best accounts that we have read and contains a detailed record of Dr. Sampson's important researches as to the method in which the disease spreads and the relative frequency of the involvement of the glands and of the cellular tissue of the pelvis. The illustrations are of the greatest artistic merit and importance and reflect great credit on Professor Max Brödel. The abdominal route in dealing with the disease is favoured. For the important details with regard to the avoidance of damage to the ureters we must refer our readers to the book itself. The method of operating recommended, based upon the anatomical studies of Dr. Sampson on the blood-supply of the ureters, is a very good one and renders the risk of damaging these structures almost *nil*. We are interested to see that stress is laid on the danger and often unsatisfactory results obtained in many cases of uretero-vesical implantation. In the chapter on intestinal complications the crushing operation for the removal of the appendix is described and recommended.

We can hardly praise this book too highly. It is a fitting record of the genius of its author and of the remarkable work accomplished in the Johns Hopkins Hospital under his direction and supervision. It is true that the book contains mainly the opinions and the practice of Professor Kelly and it might be objected that too little attention is paid to the work and opinions of other surgeons. In this, however, lies one of the main merits of the book—that it is founded upon the practice of one school, and it derives much of its value from the fact that the reputation of the Johns Hopkins University stands so high that any record of the work done there cannot but be helpful to others. Professor Kelly's "Operative Gynecology" must be read and studied by any gynæcologist who wishes to keep abreast of the advances which daily are being made in his specialty, and he will not fail to derive the utmost pleasure and profit from his

Correspondence.

"Audi alteram partem."

SHIPS' SURGEONS AND MEDICAL EQUIPMENT.

To the Editors of THE LANCET.

SIRS,—Having just performed a voyage as surgeon on a passenger boat trading from Australia to England and formed a *few impressions as to the medical* side of things and the provision made for sickness in the way of drugs, &c., I have thought I might set these down with some profit.

Before sailing I took the trouble to run down and see what drugs and instruments there were, and I found that things according to Board of Trade regulations were supplied and that departure from the strict letter of these was not *encouraged*. Instruments were well provided, but there was only one artery forceps among the whole outfit. I requisitioned for two or three more but found after sailing these were not got, on the ground that the Board of Trade regulations did not require more than one. There were about 170 souls on board and the voyage would take at least seven weeks. As a matter of fact, it took about eight weeks. It can be easily seen that in the admitted possibility of a serious accident involving *the severance of several* arteries one useful pair of forceps was but a poor stand-by to fall back on.

The choice of drugs was of a very peculiar character. There was no nux vomica, sulphate of soda, ammonium chloride, or any one of the infusions provided. Nor was there any adequate provision of gauze. Carbolic acid and a little perchloride solution was the only antiseptic provided, unless one would call boric acid such. There was no picric acid for burns.

Now all this was specially noticeable in view of the fact that as to catering for the feeding, as to comfort, and as to attendance upon the passengers the ship was exceedingly well found. Clearly there seemed an inability to recognise the necessity of so providing that the important duty of the surgeon should be efficiently carried out. His place in the scheme of things seems not yet definitely settled. He is apparently as yet but an accretion, an accident, and hence there is an inability to gauge the place in the scale that he and his duties hold. He himself is treated with courtesy and consideration and his representations are received with respect; but any definite action is avoided by an attitude of *non possumus*. The dispensary had no seat or bench, and it was only the courtesy and good sense of the commander that provided such after the voyage had begun. Now it would be unreasonable in the extreme to expect the comfort of a surgery or the completeness of provision of a hospital dispensary, but ought not a little more latitude to be allowed the *doctor so as to give him every encouragement to perform his* duties with pleasure and satisfaction to himself and his patients, who need just as much sympathy and care at sea as on shore?

It might be objected that really so very little sickness occurs on board that it would be foolish to go to any great expense and make elaborate provision for contingencies that *could only arise on the rarest occasions.* In answer to this let me give an inadequate list of what I had to deal with on the voyage: orchitis and epididymitis, an old fracture of metatarsal bone with severe strain and adhesions, a case of alcoholism, two axillary abscesses and one inguinal abscess, one case of chancre, two of cystitis, one of renal calculus, one case suggestive of renal calculus; obscure case in many respects; one of prostatic enlargement, two of varicella, one of pertussis, one of acute laryngitis with adenoids as an aggravation, very *severe*; two burns, several injuries of shins leading to ulcers, two cases of liver derangement with gastric complications, one phthisis pulmonalis, far advanced; several cases of lumbago, bronchial catarrh, and pharyngitis (three). Then there were sundry cases of catarrh, indigestion, and, of course, the large number of constipation cases we all expect among firemen and others. I submit this is a formidable list for a few weeks and I allow it is exceptional. But no chain is stronger than its weakest link, and on starting no one ever thought such a deal of sickness would occur. But pity the doctor who is called upon to meet the situation. Certainly nothing *very* serious resulted, but it might have in other circumstances. Some drugs were run out of on the voyage and I desired to get them replaced. But then I found that the company objected to any drugs being bought at any *other* ports than London and it was there down in their regulations for the guidance of the surgeon. But the captain got them all the same. But how is a man to get satisfactorily through his work, small and unimportant as it may be, if he is hampered by considerations such as these?

There is one more point I must draw attention to. Is it comportable with the dignity and efficiency of the work of the doctor that his dispensary should be next to a urinal and his cabin and the dispensary both lie in a dark alleyway which it was impossible to keep clean or properly lighted? This alleyway constituted the one means of access for the crew to go to their quarters, for the stores to be carried backwards and forwards, and for the provisions to be conveyed to the crew and the steerage passengers, and for all and sundry to go to the bar. The traffic along it was thus very great and at times it was impassable. To crown all, its width was about four feet. Now surely it is time such a state of things was rectified. Of course we must keep in view that the doctor and his dispensary are accessible to *every class of* passenger at all times But *this* applies just as much to saloon passengers as to others, and to invite such to pass through dirty and dark alleyways where they must brush against coal dust and step through slops is a blunder as well as a crime. *Structurally, surely,* in this day of marine architecture *in excelsis* there can be no insuperable difficulty in so placing cabin and dispensary so that they can be accessible in unexceptionable neighbourhoods and with approaches that can be kept both clean and dry?

Now, finally, is it not time that Board of Trade lists of drugs should be revised? When were these schedules *last over-hauled and corrected? It seems only right that they should* be so drawn up as not to allow any latitude to such shipping companies as are not above playing fast and loose with them in their pursuit of a cheese-paring policy to make them really a means of hampering their medical officer. Of course, it is ever the effect, in these ingenious days, of any prescriptive legislation to have a restrictive result, because while it says what must be *taken it is ever open* to any one to say that nothing outside its provisions shall be taken Both the character of drugs and their quantities *ought* to be more or less at the option and direction of the surgeon, inasmuch as every medical man has certain drugs with which he works and has confidence in. As a *matter of fact* these positions are more or less filled by recently qualified men who have *not yet* had occasion to have their special *fancies and dependencies*. But even such in their *hospital* work will have a choice dictated by experience. I have deliberately re*frained from specifying the ship* and company that have given *me my text,* because I am clear that the conditions here are more or less prevalent in all lines but the *very best.* As to them I have no experience, so cannot say. But I have frequently travelled on other lines, and can assert that the conditions described above are the best I have met with.

Trusting that you will consider this matter of sufficient importance *to* justify insertion,

I am, Sirs, yours faithfully,

G. A. VAN SOMEREN, M.D. Edin.

Sydney, N S Wales.

RHEUMATOID ARTHRITIS.

To the Editors of THE LANCET.

SIRS,—*In common with others I read with much* interest your annotation entitled "Rheumatoid Arthritis" which appeared in THE LANCET of Sept. 7th, p. 725. In considering the trend of the discussion on *this subject* at the recent annual meeting you draw attention to the almost complete absence of any allusion to the neural theory of the origin of the disease, and this notwithstanding *the fact that* some authorities like Spender, Latham, and others, still hold it to be the correct view. This silence on the subject of the neural theory as opposed to the infective would seem to *carry with it the inference either that* the neural theory has been thoroughly weighed, found wanting, and no longer merits serious attention, or that there is something *inherently* antagonistic in the two *theories* which *precludes* anything of the nature of a compromise between their respective advocates.

The truth of the matter, *it seems to me* is that neither *of*

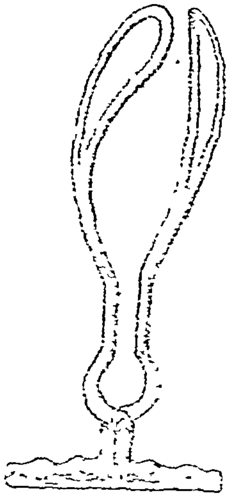
This view is in opposition to the conclusion of A. O. Lockhead and W. Cramer, published in the *Biochemical Journal*, Vol. II. 2. On the Nature of the Fat contained in the Liver, Kidney, and Heart, by Percival Hartley, Grocers' Company Research Scholar. The chief conclusions at which the author arrives are that the higher fatty acids from the liver include, in addition to saturated acids and acids of the oleic series, considerable quantities of acids of the series $C_nH_{2n-4}O_2$, $C_nH_{2n-6}O_2$, and possibly $C_nH_{2n-8}O_2$; that the fatty acids from the kidney and the heart muscle have iodine values of the same order as those of the liver fatty acids; and that the higher fatty acids from the organs undergo change on exposure to the air, the iodine value diminishing and a large proportion becoming insoluble in petroleum ether. 3. Metabolism during Starvation, Part II., Inorganic, by E. P. Cathcart, M.D. Glasg., and C. E. Fawsitt, D.Sc. Glasgow University. 4. The Action of Caffeine on the Capacity for Muscular Work, by W. H. R. Rivers and H. N. Webber. The authors show that in two subjects caffeine produced an increase in the capacity for muscular work but in one the action continued throughout the whole of six sets of ergograms and in the second a decided fall below the normal was observed towards the close of each set of six ergograms. 5. The Haldane-Smith Method of Estimating the Oxygen Tension of Arterial Blood, by W. A. Osborne, University of Melbourne. The author considers that Haldane and Smith were not justified in concluding from their researches that the oxygen tension of arterial blood is higher than that of the alveolar air because the colorimetric method employed is inaccurate and because no account was taken of the counter diffusion of O and CO_2 on the CO. 6. On Sulphhæmoglobin, by T. Wood Clarke and W. H. Hurtley, St. Bartholomew's Hospital. 7. Concerning Cystinuria and Diamines, by F. H. Thiele, M.D., pathologist to University College Hospital. This number of the journal contains the Proceedings of the Physiological Society for May 18th, June 22nd, and July 20th, 1907.

The Biochemical Journal. Edited by BENJAMIN MOORE, M.A., D.Sc., and EDWARD WHITLEY, M.A. Vol. II., No. 9. August 20th, 1907. Biochemical Department, Johnston Laboratories, University of Liverpool.—The contents of this part are: (1) The Electrolytes in Pathological Body-Fluids, by Oskar C. Gruner, M.B. Lond., clinical pathologist, Leeds General Infirmary; (2) Abnormal Fat Assimilation associated with Some Diseases of the Intestine, by Owen T. Williams, M.D., B.Sc. Lond., medical registrar, Liverpool Royal Infirmary; (3) A Note on the Reduction of Alkaline Copper Solutions by Sugar, by Stanley R. Benedict, from the Sheffield Laboratory of Physiological Chemistry, Yale University, New Haven, Conn., U.S.A.; (4) On the Effect of Narcotic Agents in the Detachment of Electrolytes from Cell Proteins, by Herbert E. Roaf, M.D. Toronto, lecturer on physiology, University of Liverpool, and E. Alderson, M.D. Liverp.; and (5) On Some Applications of Safranin as a Test for Carbohydrates, by Hugh MacLean, M.D. Aberd., lecturer on chemical physiology, University of Aberdeen. Unlike many other tests for sugar, safranin is absolutely unaffected by uric acid or urates, hippuric acid, creatinin, creatin, chloral, chloroform, hydrogen peroxide, salts of hydroxylamine, pyrocatechin, or hydroquinone. It is essentially a reagent for indicating the presence of carbohydrates in general.

New Inventions.

NEW DESIGN OF MIDWIFERY FORCEPS.

I ASK permission by the medium of the columns of THE LANCET to draw the attention of the medical profession to a new design of midwifery forceps. It has often occurred to me during a lengthened experience of midwifery practice that there was a manifest failure to provide the chief essential of such forceps—viz., a means of *traction*—in the ancient instrument still in use by every general practitioner of the present day. It is with this excuse I submit the accompanying sketch wherein this failure is to a considerable extent obviated by having each handle at right angles to the shank. At first sight it may seem difficult of application, but from repeated use I find it simpler. Each handle is 2½ inches, this being necessary to get a firm enough hold for introducing, making, when locked with its fellow, 5 inches of somewhat uncomely length, and yet not too long if each hand of the operator is on each handle of the instrument when enforced traction is necessary; in practice this does not interfere with its efficiency. In the ordinary position with the thighs flexed and kept apart, or on the back with the thighs apart, the joined handle is not, as one might expect, in the way in the movement necessary for complete delivery. Where rotation is practised the means of doing so by this instrument is simplified. The other accessories of forceps, such as for compression by the addition of a screw, or for axis-traction by a handle, may be applied to the shank or other part of this instrument as they are to others; for my part I prefer keeping the handles locked by some material such as tape or string that can be so easily divided or unwound when not required further.



Messrs. Mayer and Meltzer of London and Melbourne have kindly arranged for the supply of this instrument and I have to thank them for their assistance in carrying out my design.

T. TAYLOR DOWNIE, M.B., C.M. Glasg.,
Honorary Midwifery Surgeon, Women's Hospital, Melbourne, Australia.

AN IMPROVED RETINOSCOPICAL MIRROR.

FROM the illustration it will be seen that two mirrors (one concave and one flat), 1¾ inches in diameter, are hinged together so as mutually to protect one another. This is a well-known device but the improvement consists in having on the back of the concave mirror a small triangular carrier. This has three perforations carrying a + 2 D. and a + 4 D. lenses, the centre one being unglassed. When examining by the indirect method either at will can be brought over the sight hole of the mirror. The advantage of examining with + lenses gives not only increased magnification but lessens the distance at which the observer has to stand from the eye of the patient. To enable one to clean the lenses the carrier is hinged on itself. The sight holes in both mirrors are six millimetres in diameter which is larger than commonly made. Messrs. Hawes of Leadenhall-street, London, E.C., made the instrument at my suggestion some years ago and as it has proved of value to myself and recommended itself to other ophthalmic surgeons it may be worth the attention of others. A pupilometer is fitted to the back of the flat mirror.

SHIPS' SURGEONS AND MEDICAL EQUIPMENT.

To the Editors of THE LANCET.

SIRS,—Having just performed a voyage as surgeon on a passenger boat trading from Australia to England and formed a few impressions as to the medical side of things and the provision made for sickness in the way of drugs, &c., I have thought I might set these down with some profit.

Before sailing I took the trouble to run down and see what drugs and instruments there were, and I found that things according to Board of Trade regulations were supplied and that departure from the strict letter of these was not encouraged. Instruments were well provided, but there was only one artery forceps among the whole outfit. I requisitioned for two or three more but found after sailing these were not got, on the ground that the Board of Trade regulations did not require more than one. There were about 170 souls on board and the voyage would take at least seven weeks. As a matter of fact, it took about eight weeks. It can be easily seen that in the admitted possibility of a serious accident involving the severance of several arteries one useful pair of forceps was but a poor stand-by to fall back on.

The choice of drugs was of a very peculiar character. There was no nux vomica, sulphate of soda, ammonium chloride, or any one of the infusions provided. Nor was there any adequate provision of gauze. Carbolic acid and a little perchloride solution was the only antiseptic provided, unless one would call boric acid such. There was no picric acid for burns.

Now all this was specially noticeable in view of the fact that as to catering for the feeding, as to comfort, and as to attendance upon the passengers the ship was exceedingly well found. Clearly there seemed an inability to recognise the necessity of so providing that the important duty of the surgeon should be efficiently carried out. His place in the scheme of things seems not yet definitely settled. He is apparently as yet but an accretion, an accident, and hence there is an inability to gauge the place in the scale that he and his duties hold. He himself is treated with courtesy and consideration and his representations are received with respect; but any definite action is avoided by an attitude of *non possumus*. The dispensary had no seat or bench, and it was only the courtesy and good sense of the commander that provided such after the voyage had begun. Now it would be unreasonable in the extreme to expect the comfort of a surgery or the completeness of provision of a hospital dispensary, but ought not a little more latitude to be allowed the doctor so as to give him every encouragement to perform his duties with pleasure and satisfaction to himself and his patients, who need just as much sympathy and care at sea as on shore?

It might be objected that really so very little sickness occurs on board that it would be foolish to go to any great expense and make elaborate provision for contingencies that could only arise on the rarest occasions. In answer to this let me give an inadequate list of what I had to deal with on the voyage: orchitis and epididymitis, an old fracture of metatarsal bone with severe strain and adhesions, a case of alcoholism, two axillary abscesses and one inguinal abscess, one case of chancre, two of cystitis, one of renal calculus, one case suggestive of renal calculus, obscure case in many respects; one of prostatic enlargement, two of varicella, one of pertussis, one of acute laryngitis with adenoids as an aggravation, very severe; two burns, several injuries of shins leading to ulcers, two cases of liver derangement with gastric complications, one phthisis pulmonalis, far advanced; several cases of lumbago, bronchial catarrh, and pharyngitis (three). Then there were sundry cases of catarrh, indigestion, and, of course, the large number of constipation cases we all expect among firemen and others. I submit this is a formidable list for a few weeks and I allow it is exceptional. But no chain is stronger than its weakest link, and on starting no one ever thought such a deal of sickness would occur. But pity the doctor who is called upon to meet the situation. Certainly nothing *very* serious resulted, but it might have in other circumstances. Some drugs were run out of on the voyage and I desired to get them replaced. But then I found that the company objected to any drugs being bought at any other ports than London and it was there down in their regulations for the guidance of the surgeon. But the captain got them all the same. But how is a man to get satisfactorily through his work, small and unimportant as it may be, if he is hampered by considerations such as these?

There is one more point I must draw attention to. Is it comportable with the dignity and efficiency of the work of the doctor that his dispensary should be next to a urinal and his cabin and the dispensary both be in a dark alleyway which it was impossible to keep clean or properly lighted? This alleyway constituted the one means of access for the crew to go to their quarters, for the stores to be carried backwards and forwards, and for the provisions to be conveyed to the crew and the steerage passengers, and for all and sundry to go to the bar. The traffic along it was thus very great and at times it was impassable. To crown all, its width was about four feet. Now surely it is time such a state of things was rectified. Of course we must keep in view that the doctor and his dispensary are accessible to every class of passenger at all times. But this applies just as much to saloon passengers as to others, and to invite such to pass through dirty and dark alleyways where they must brush against coal dust and step through slops is a blunder as well as a crime. Structurally, surely, in this day of marine architecture *in excelsis* there can be no insuperable difficulty in so placing cabin and dispensary so that they can be accessible in unexceptionable neighbourhoods and with approaches that can be kept both clean and dry?

Now, finally, is it not time that Board of Trade lists of drugs should be revised? When were these schedules last overhauled and corrected? It seems only right that they should be so drawn up as not to allow any latitude to such shipping companies as are not above playing fast and loose with them in their pursuit of a cheese-paring policy to make them really a means of hampering their medical officer. Of course, it is ever the effect, in these ingenious days, of any prescriptive legislation to have a restrictive result, because while it says what must be taken it is ever open to any one to say that nothing outside its provisions shall be taken. Both the character of drugs and their quantities ought to be more or less at the option and direction of the surgeon, inasmuch as every medical man has certain drugs with which he works and has confidence in. As a matter of fact these positions are more or less filled by recently qualified men who have not yet had occasion to have their special fancies and dependencies. But even such in their hospital work will have a choice dictated by experience. I have deliberately refrained from specifying the ship and company that have given me my text, because I am clear that the conditions here are more or less prevalent in all lines but the *very best*. As to them I have no experience, so cannot say. But I have frequently travelled on other lines, and can assert that the conditions described above are the best I have met with.

Trusting that you will consider this matter of sufficient importance to justify insertion,

I am, Sirs, yours faithfully,

Sydney, N.S. Wales. G. A. VAN SOMEREN, M.D. Edin.

RHEUMATOID ARTHRITIS.

To the Editors of THE LANCET.

SIRS,—In common with others I read with much interest your annotation entitled "Rheumatoid Arthritis" which appeared in THE LANCET of Sept. 7th, p. 725. In considering the trend of the discussion on this subject at the recent annual meeting you draw attention to the almost complete absence of any allusion to the neural theory of the origin of the disease, and this notwithstanding the fact that some authorities like Spender, Latham, and others, still hold it to be the correct view. This silence on the subject of the neural theory as opposed to the infective would seem to carry with it the inference either that the neural theory has been thoroughly weighed, found wanting, and no longer merits serious attention, or that there is something inherently antagonistic in the two theories which precludes anything of the nature of a compromise between their respective advocates.

The truth of the matter, it seems to me, is that neither of the view that the proposals are not adapted to India or of any practical utility. Organisation on adequate and proper lines is the first essential in combating plague. Neither at the beginning of the plague nor after 11 years' experience does this fact appear to have impressed itself upon the Indian Government. It was not recognised when the initial mistake was made of reinforcing its medical service in 1897 by large numbers of troops. This circumstance is mentioned in the latest despatch apparently as rather a creditable proceeding instead of one which did more to assist in the complete failure which it deplores and in raising hostility to every measure connected with plague than any other factor. Nor was it recognised in the inoculation campaign in 1902, when the plague service was raised to 77 European medical officers, 37 of whom came from England, for the organisation was still inadequate for the purposes intended. Many of the more important operations had accordingly by order to be intrusted to compounders—i.e., to assistants very little different from Indian villagers, and in case of great stress of work the duty of actually opening the bottles of the prophylactic was to be intrusted to any of the intelligent villagers gathered together for the inoculation. We know the result. The campaign failed and the onus of the failure was hastily and mistakenly placed on the Bombay laboratory instead of on an inadequate organisation and the absence of coördination in the different departments working on plague.

◆

Flies as Carriers of Disease.

ONE of the most striking of the discoveries made by pathologists in recent years has been that of the important part played by insects of various kinds in the conveyance of disease to mankind and to the lower animals. An entirely new field of research has thus been opened up and the revelation of a novel source of danger has suggested the adoption of prophylactic measures which would have seemed ridiculous only a generation ago. The first inkling of this source of infection was the hypothesis put forward by Sir PATRICK MANSON as to the origin of malarial infection in the bite of the mosquito, a suggestion brilliantly converted into certainty by the work of ROSS among our own countrymen and of the Italian observers GRASSI and BIGNAMI. It was not long before facts were brought forward tending to attribute to the insect world the responsibility for other serious diseases. In the case of yellow fever, although the causal agent has not yet been identified, it is pretty definitely established that another species of mosquito conveys the infection, an interesting point of contrast with malaria lying in the probability that the insect is here the definitive and man only the intermediate host of the parasite. Another disease produced by the bite of a blood-sucking insect is the deadly African lethargy or sleeping sickness caused by a trypanosome conveyed by the fly glossina palpalis. Nor is it only winged insects which carry infection, for the fleas which infest rats are generally believed to convey infection to human beings in epidemic outbreaks of plague. In this country we are fortunately not exposed to any serious dangers from the bites of disease-bearing insects, though from time to time cases of dangerous and even fatal cellulitis are reported due to the bite of a horse-fly infected with some virulent germ. But it is not only by direct inoculation that infection may be spread: food may be contaminated with pathogenic bacteria carried by insect scavengers and its consumption may give rise to fatal mischief. The very interesting paper by Dr. R. M. BUCHANAN[1] which recently appeared in our columns emphasises the reality of the danger to which we may be exposed by the agency of the common varieties of house-fly. Dr. BUCHANAN first points out how well adapted is the foot of the fly for carrying on it particles of any adhesive material over which the insect has crawled. Particles loaded with bacteria will readily adhere to its bristles and pads, to be smeared over the next object on which the fly settles. Food of almost all kinds attracts flies, which crawl over it if it is solid and too often fall into it when it is liquid, so that infection readily occurs. In Dr. BUCHANAN'S experiments flies were made to crawl over Petri dishes containing some nutrient medium and the resulting colonies of bacteria were counted and studied. It is satisfactory to find that flies caught in an enteric ward of a fever hospital did not give rise to any colonies of typhoid bacilli when thus treated; even when they were caused to crawl over actual fæcal matter the number of typhoid colonies which developed was very small as compared with the saprophytic organisms present. Still some colonies were observed to form. Staphylococci and tubercle bacilli were also capable of conveyance by the same means. Much more striking results were, however, obtained with the organisms of some epizootic diseases. Flies which had crawled over the carcass of a pig dead from swine fever readily conveyed a large number of the causal organisms to artificial media, and even more marked infection occurred from insects which had been brought into contract with a guinea-pig dead from anthrax. The bacilli of glanders were also carried on the feet of flies. Nor is Dr. BUCHANAN the only authority who has called attention to flies as a means of conveying disease. A notable communication by Dr. H. H. TOOTH,[2] based on his experiences during the South African war, drew a striking picture of the probable responsibility of the swarms of flies for the spread of the epidemic of enteric fever among the British troops in the field, and a similar view was maintained by Dr. A. B. DUNNE[3] who noted that the incidence and remission of typhoid infection corresponded very closely with the appearance of flies in the hot season and their disappearance as cold weather followed. It would seem, therefore, that it is not only in the laboratory but also under natural conditions that flies may act as carriers of disease.

The question, then, as to the actual amount of danger attributable in this country to such a source of infection is worthy of careful study. Fortunately in temperate climates flies do not abound to the same extent as in tropical and subtropical conditions. There they are capable of rendering life almost intolerable by their very multitude; those who have suffered from them will appreciate the horrors of the Egyptian Plague and sympathise with those ancient races who identified the chief power for evil with

Flies as Carriers of Disease.

ONE of the most striking of the discoveries made by pathologists in recent years has been that of the important part played by insects of various kinds in the conveyance of disease to mankind and to the lower animals. An entirely new field of research has thus been opened up and the revelation of a novel source of danger has suggested the adoption of prophylactic measures which would have seemed ridiculous only a generation ago. The first inkling of this source of infection was the hypothesis put forward by Sir PATRICK MANSON as to the origin of malarial infection in the bite of the mosquito, a suggestion brilliantly converted into certainty by the work of ROSS among our own countrymen and of the Italian observers GRASSI and BIGNAMI. It was not long before facts were brought forward tending to attribute to the insect world the responsibility for other serious diseases. In the case of yellow fever, although the causal agent has not yet been identified, it is pretty definitely established that another species of mosquito conveys the infection, an interesting point of contrast with malaria lying in the probability that the insect is here the definitive and man only the intermediate host of the parasite. Another disease produced by the bite of a blood-sucking insect is the deadly African lethargy or sleeping sickness caused by a trypanosome conveyed by the fly glossina palpalis. Nor is it only winged insects which carry infection, for the fleas which infest rats are generally believed to convey infection to human beings in epidemic outbreaks of plague. In this country we are fortunately not exposed to any serious dangers from the bites of disease-bearing insects, though from time to time cases of dangerous and even fatal cellulitis are reported due to the bite of a horse-fly infected with some virulent germ. But it is not only by direct inoculation that infection may be spread: food may be contaminated with pathogenic bacteria carried by insect scavengers and its consumption may give rise to fatal mischief. The very interesting paper by Dr. R. M. BUCHANAN[1] which recently appeared in our columns emphasises the reality of the danger to which we may be exposed by the agency of the common varieties of house-fly. Dr. BUCHANAN first points out how well adapted is the foot of the fly for carrying on it particles of any adhesive material over which the insect has crawled. Particles loaded with bacteria will readily adhere to its bristles and pads, to be smeared over the next object on which the fly settles. Food of almost all kinds attracts flies, which crawl over it if it is solid and too often fall into it when it is liquid, so that infection readily occurs. In Dr. BUCHANAN'S experiments flies were made to crawl over Petri dishes containing some nutrient medium and the resulting colonies of bacteria were counted and studied. It is satisfactory to find that flies caught in an enteric ward of a fever hospital did not give rise to any colonies of typhoid bacilli when thus treated; even when they were caused to crawl over actual fæcal matter the number of typhoid colonies which developed was very small as compared with the saprophytic organisms present. Still some colonies were observed to form. Staphylococci and tubercle bacilli were also capable of conveyance by the same means. Much more striking results were, however, obtained with the organisms of some epizootic diseases. Flies which had crawled over the carcass of a pig dead from swine fever readily conveyed a large number of the causal organisms to artificial media, and even more marked infection occurred from insects which had been brought into contact with a guinea-pig dead from anthrax. The bacilli of glanders were also carried on the feet of flies. Nor is Dr. BUCHANAN the only authority who has called attention to flies as a means of conveying disease. A notable communication by Dr. H. H. TOOTH,[2] based on his experiences during the South African war, drew a striking picture of the probable responsibility of the swarms of flies for the spread of the epidemic of enteric fever among the British troops in the field, and a similar view was maintained by Dr. A. B. DUNNE[3] who noted that the incidence and remission of typhoid infection corresponded very closely with the appearance of flies in the hot season and their disappearance as cold weather followed. It would seem, therefore, that it is not only in the laboratory but also under natural conditions that flies may act as carriers of disease.

The question, then, as to the actual amount of danger attributable in this country to such a source of infection is worthy of careful study. Fortunately in temperate climates flies do not abound to the same extent as in tropical and subtropical conditions. There they are capable of rendering life almost intolerable by their very multitude; those who have suffered from them will appreciate the horrors of the Egyptian Plague and sympathise with those ancient races who identified the chief power for evil with are, the official report states, "in most unsuitable and thickly populated localities." The report adds that :—

[3] Ibid., March 8th, 1902, p. 662.

> A special department is now formed under the efficient charge of Mr. Watson, M.R.C.V.S., for the purposes of meat, fish, and food inspection generally, but it is obvious that he can never adequately control the meat-supply of the city until the private slaughter houses are abolished and the meat killed under his supervision in the abattoir. The Dairy Inspection Department has also, as mentioned before, been placed under his supervision as well as the inspection of slaughter-houses. The whole question, not only of meat but of food inspection generally, is a wide and vitally important one, and requires close and unremitting attention on the part of the public health committee.
>
> Slaughter-houses situated in such crowded localities as Moore-street, Townsend-street, Chatham-street, Westland-row, Thomas street, Francis-street, Dorset-street are a positive nuisance to the residents in these districts.

Such is the historic aspect of the subject; and having ascertained this much I proceeded to visit the public abattoir. It is situated in the direction of Phœnix Park, just opposite, and conveniently near, the large cattle-market. If the butchers who buy their cattle there took them merely across the road to the public slaughter-house it would save them much time and trouble. But the majority prefer to drive the animals through the streets of Dublin to their private slaughter-houses. This, of course, is bad. The animals by their droppings add to the difficulty of keeping the streets clean. The barking of dogs, the shouting of men, and the lowing of the cattle add to the street noises. These animals not only impede the traffic but by reason of the blows and dog-bites which they receive and the panic into which they are thrown the disturbance caused by their journey to the Dublin cattle market is aggravated. At the slaughter-house the cattle would not only be spared the alarm of being driven through strange streets amid terrifying tramways and motor-cars, but there are adjacent fields where they could rest and graze for a few days before being killed. Also (and perhaps these form the best constructed part of the Dublin abattoir) there are the lairs or stabling attached where animals can rest and recover from the effects of travelling. The surrounding fields belong to the city of Dublin and are kept at present for grazing purposes but also in view of a probable enlargement of the slaughter-house. The sheep and cattle lairs consist of a sort of verandah with corrugated roofs, with concrete and fluted flooring, so that the liquid manure easily drains away. But there are some wooden planks at the edge of the flooring that should be removed, as they naturally absorb much of the foul moisture.

Taken altogether, I must confess that I was much disappointed with the public abattoir. It cannot for a moment be compared with any good model slaughter-house of the continent. The one excuse is that it was built in 1882; that is, before the modern principles had been generally accepted. The unpretending entrance, the very simple office for the management, the absence of uniforms, of smartness, and of that appearance of order, discipline, and dignity which conveys the impression of the majesty of government, at once proclaimed the fact that in the building and organising of its public abattoir the city of Dublin had utterly failed to understand the importance of its mission. A public slaughter-house should be an elegant edifice, kept so bright and clean and tidily regulated in every part as to constitute a demonstration of the power of science to civilise even the most brutal of occupations. Those who built the Dublin slaughter-house had evidently no knowledge of what constitutes a model modern abattoir. Thus on entering the first steps are taken on square pavement stones that go up to the doors of the slaughter sheds. Here blood and manure flow upon these stones. Yet they are not cemented, so that the subsoil is befouled. Now close at hand there is a terrace of new dwelling-houses and under them subsoil water is likely to contain some of the blood and manure from the slaughter-house. One of the great grievances against private slaughter-houses is that they contaminate the subsoil in towns, and here is a public abattoir doing the same.

To the right on entering there is a lofty hall sometimes called the meat market. Carcasses should be brought to this hall and hung so as to cool. Under the same roof there is a cold storage where for *1s. 6d.* for the first day and *1s.* for the following days a butcher may hang the meat which he cannot dispose of rapidly. The "omnibus" rails, the patent scales, the lofty, well aired, shady and cool character of this central compartment, are certainly preferable to, and more commodious than, anything to be found in a private slaughter-house. No individual butcher could afford to build anything like it for his own private use. But I have seen in the town one or two private slaughter-sheds that were, if anything, better than those of the public abattoir. To begin with, the slaughter or killing rooms at the public abattoir have exactly the same disadvantage as those in the town—namely, they are private. Certainly they can be more readily inspected, but only by reason of their construction and because they are nearer to each other. In other words, there is no slaughter-hall but there are several small compartments let out to various butchers. Indeed, butchers complained to me that these slaughter-rooms are let out to the highest bidder, thus giving special advantage to the wealthiest butchers. On the other hand, on questioning some of the town officials, I was assured that this was not the case for all the slaughter-rooms. Some were always available for the smaller butchers who would only use them for a short time. Obviously, however, it is easier to find room in a large slaughter-hall than when the same space is divided up into compartments. More important, however, than this consideration of the convenience of the butchers is the public health point of view. Obviously it is easier to watch over what is done in a large hall than in small compartments, and the latter are not so easily cleansed or ventilated. Therefore the Dublin abattoir is behind the times because it still tolerates compartments.

The slaughter rooms or compartments are also in themselves defective. The walls very properly are of glazed bricks up to a certain height but somehow the splashings go above this, striking and sticking upon the porous part of the wall. In one instance some offal must have been thrown up purposely for large pieces were adhering to the walls at a height of ten feet or more. It suggested that pieces of fat and offal had been used as missiles in a free fight. Such disorder would, in Germany, be absolutely incomprehensible; it would drive the officials to distraction. To treat Government property with such scant respect would shock the German mind more than words can express and it is necessary to remember that it is to Germany we must look for the best example in regard to public abattoirs. All splashing above the glazed part or dado cannot be satisfactorily cleansed away and its occurrence should be rendered impossible. But worse than this, because so easy to avoid and yet so abominable in itself, were the horrible wooden tables riveted to the walls on which the intestines are laid so that the fat may be removed therefrom to make butter substitutes. Between these tables and the wall there is a space from half to an entire inch wide in which fat, offal, blood, dust, and dirt cake and remain for days, weeks, perhaps months. For such work no wood should be used. In any case, if there be wooden tables they should stand on their own four legs and be removeable from the wall so that they can be cleaned on all four sides and that the walls can also be cleaned. There is evidently no sanitary police force here.

Immediately behind each of these slaughter-rooms or compartments there is a small stable or lair where animals are kept for a short time before they are killed. These small stables are very dark; they are reeking with manure, and it would be no easy matter to clean them thoroughly. The manure oozes out of them and runs on to the uncemented pavement opposite a second row of slaughter-sheds or rooms. These have also got similar stables behind them. The carcasses from the second row of slaughter-rooms should at once be removed to the large hall where the meat is intended to hang and to cool. This removal of carcasses can be easily effected from the first, but not so easily from the second, row of slaughter-rooms. Consequently a good deal of the meat is simply hung up in the open outside the second row of slaughter-rooms. The carcasses are then exposed to the effluvia from the stables of the front row which face them and of the second row behind them and also to the dust and dirt caused by the traffic; to the rain or sunshine; in fact, to multiple influences likely to compromise the quality and the cleanliness of the meat. This ought not to be; the carcasses should at once be taken to the cooling hall built for their reception; but some butchers assured me that as they could not do this easily they did not do it at all, forgetting that in such matters there should be no option allowed. It is not a question of the butchers' convenience but of the proper preservation and preparation of meat.

There are but few pigs killed at the Dublin abattoir, as the figures given above show, but the place where they are killed is much superior to that provided for horned cattle and can easily be kept clean. With all its defects the public body must look for guidance in all matters of health affecting its district. It is essential, therefore, that the conditions of appointment for these officers should be such as to enlist the services of the best men and to leave them sufficient time to devote to the important duties of their office. Further, these officers must be protected against undue influence brought to bear upon them by the representatives of local interests which may be affected by strict sanitary administration. It is notorious that in all these respects the present condition of affairs is highly unsatisfactory. Fair remuneration and fixity of tenure are alike wanting. In not one of the group of districts dealt with in the present series of reports is a medical officer of health appointed to give his whole time to the duties of his post. Further, for such time as they are able to devote to health matters these officers are paid salaries which are almost insulting. Thus at Denton the medical officer of health receives £40 per annum, while the inspector of nuisances is paid £250. At Lees and at Audenshaw the salaries of the medical officers are £20 and at Hurst £30. At Ashton-under-Lyne the medical officer of health, who had been paid £130 a year, died, and the town council appears to have thought the occasion a happy opportunity for retrenchment, for it not only passed over the candidate for the office who, in the opinion of the Local Government Board inspector, was best qualified to hold it, but it appointed a new officer *for only six months* at a salary of £40 for that period. Nor is this instance of cheese-paring policy unique, for, as we noted last week, the town council at Southend-on-Sea has similarly distinguished itself, practically dismissing a very capable and efficient officer and reducing the salary attached to the post from £600 to £500 per annum. Naturally, the Local Government Board does not view such proceedings with favour, but the powers of the Board are limited. At Ashton-under-Lyne the sanction of the Board was given to the raising of a loan for sanitary improvements on certain conditions; but the conditions were not fulfilled and seemingly no power exists to enforce them. It is clearly desirable that the powers of the central body should be enlarged, so as to enable it to deal with recalcitrant local authorities. If according to the elegant metaphor of Mr. WINSTON CHURCHILL it is desirable "to ginger" the local fathers in the matter of small holdings, *much more is it* needful in the domain of hygiene. It is certain that in many instances local bodies are unsuited to administer the laws of health, as personal interests are too likely to intervene and to warp their judgment. A change in the law is desirable so that the post of medical officer of health should be permanent, appointments being carefully supervised by the Local Government Board; and provision should be made that if a sanitary authority refuses to carry out the advice of its expert officer, an appeal should automatically be made to the Government department. Payment of health officers should be adequate to enable them to give their whole time to their public work, and if any district is too small or too poor to afford this, amalgamation of adjacent areas for purposes of sanitary administration should be insisted upon.

But it is not only the sluggishness of local authorities or the overworked state of their medical officers that stands in the way of progress. The habits of the *classes* who inhabit insanitary areas must be changed. No landlord can be expected to spend money on improving his houses when the tenants tear up and burn the wood work, sell the leaden pipes, and prefer a condition of filth to any attempt at cleanliness and decency. That such degraded habits exist is attested by the reports before us, and the conditions which produce them call for treatment. It is to education that we must look for a remedy and, unfortunately, true education spreads slowly. Yet it does spread gradually. The sanitary condition of the country as a whole shows a marvellous advance on the old state of things, and when among the subjects taught in our elementary schools is included instruction in the rudiments of hygiene we may hope that rich and poor alike will recognise their true interests and that slums with their attendant horrors will cease to constitute a blot on our civilisation.

Annotations.

"Ne quid nimis."

PRESERVATIVES AND DYES IN FOODS.

THE United States Department of Agriculture has issued a provisional "decision" on the question of the use of dyes, chemicals, and preservatives in foods. It has been determined in general that no drug, chemical, or harmful or deleterious dye or preservative may be used. Common salt, sugar, wood smoke, potable distilled liquors, vinegar, and condiments may be used. Saltpetre is allowed pending further inquiry. No prosecution, again, is to be instituted in the case of the application of the fumes of burning sulphur (SO_2) as usually employed in the manufacture of those foods and food products which contain aldehyde, sugars, and so on, with which sulphurous acid may combine if the total amount of sulphur dioxide in the finished product does not exceed 350 milligrammes per litre in wines or 350 milligrammes per kilogramme in other food products. Of this amount 70 milligrammes may exist in the free state. Foods and food products manufactured or packed during the season of 1907 which contain sodium benzoate in quantities not exceeding one-tenth of 1 per cent. or an equivalent of benzoic acid, will be permitted provided that it has been customary to use this preservative in such foods and food products. There is clearly no intention of the department to allow the use of preservatives to be extended. The label of each package of sulphured foods *or of foods containing benzoic* acid or benzoate must bear a statement that the food is preserved with this, that, or the other preservative, as the case may be. The department will not allow any statement on the label to the effect that the article is guaranteed to conform to the requirements of the Food and Drugs Act. The use of any dye, harmless or otherwise, to colour or to stain a food in a manner calculated to conceal damage or inferiority is specifically prohibited and the use in food for any purpose of any mineral dye or any coal-tar dye except certain ones which are listed will be grounds for prosecution. Pending further investigation now proceeding certain coal-tar dyes which are made specifically for use in foods and which bear a guarantee from the manufacturer that they are free from subsidiary products and represent the actual substance the name of which they bear may be used in foods. The list contains the following colourings. *Red shades:* amaranth, ponceau 3 R., erythrosin. *Orange shade:* orange I. *Yellow shade:* naphthol yellow S. *Green shade:* light green S.F. yellowish. *Blue shade:* indigo disulpho acid. So far the use of copper for colouring peas has not been finally determined, but for the present all vegetables the infirmary by a reference to other cities, and mentioned that in one of the largest cities in the empire a similar hospital to the General Infirmary not only got all its water free of charge but was also in receipt of a subscription from the municipality. At present the amount paid by the infirmary was £356 per annum and he expressed the hope that the council would see its way to exempt the infirmary from the operation of the proposed increase of rate. Mr. Lupton rightly enlarged on the difference which should exist in the treatment of a rate-supported or rate-aided institution and one supported by voluntary contributions. To increase the rates in the former class is, as he said, in a measure to take money out of one pocket and put it into another.

Nursing at the General Infirmary.

The maintenance of a high standard of efficiency in the nursing at hospitals and infirmaries is, as one might expect, a source of great expense, and any increase in the number of the staff should be carefully considered before it is carried into effect. Some months ago a committee of the board, consisting of laymen and members of the honorary staff, was appointed to consider the nursing arrangements and to report to the board. A good many meetings were held and information was obtained from most of the larger metropolitan and provincial hospitals. It may be pointed out that the General Infirmary at Leeds undertakes, as its name implies, all kinds of work, and that there are special departments for diseases of women, special medical and surgical wards for children, special departments for ophthalmic and aural cases, and a very large out-patient and casualty department. The number of in-patients last year was 7052 and the average number in the infirmary at one time was 365. The number of patients treated at the Robert Arthington and Ida semi-convalescent homes was 1247. At the time when the committee of inquiry was appointed the staff consisted of the lady superintendent and her assistant, with a nursing staff of 101, which included 16 nursing sisters or charge nurses. Each of the nine large wards, which accommodate 28 or 32 patients, is in charge of a sister with a varying number of nurses under her. Six of the wards are in groups of two and each group of two is under the charge of a sister in the same way. The remaining four sisters are in charge of the casualty and out-patient department, the theatres, the supervision of the night nursing and the two semi-convalescent hospitals, and each of these has a varying number of nurses under her. The committee felt that a case was made out for an increase in the number of the nurses and special attention was given to the conditions of the nursing during the night and to the question of the occasional employment of extra nurses at times of stress from some of the various nursing institutions in the city. It was felt by the committee that the demand for these extra nurses, mainly required when it is necessary to have the services of one or more nurses entirely devoted to one patient, was of so fluctuating a character that it would be unwise to make any attempt to meet this by an increase in the staff, and in future, as in the past, outside nurses will from time to time be engaged. The night nursing has been under the immediate supervision of the night sister and her assistant. In each of the nine large wards and in each group of the smaller wards, as above explained, there is one night nurse but one of the heavier wards is provided with two. There are also three nurses who are moved about by the night sister to meet the varying periods of activity in the different wards, and the making of beds and the other routine duties of the wards are arranged in harmony with this. There was much discussion as to whether the increase in the night staff should take the form of placing extra nurses in the heavier wards or in an increase in the number of these moveable nurses, and the latter plan was unanimously decided upon. There will be an increase in the number of nurses on duty in the theatres and in some of the wards, and at a recent meeting of the board the recommendation of the committee that ten extra nurses should be engaged was ratified. Accommodation for nine of the ten extra nurses will be provided in two empty houses belonging to and adjoining the infirmary, after some structural alterations at a probable cost of about £300, and in estimating the future expenses of the infirmary an additional sum of £600 per annum must be reckoned for as the cost of the additional nurses recommended by the committee. The nursing staff will therefore now consist of 111 sisters and nurses exclusive of the lady superintendent and her assistant.

Sept. 10th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Merthyr General Hospital.

THE General Hospital at Merthyr Tydfil has been enlarged several times since its establishment in 1887. Last year an addition was made to the accommodation on the female side at the cost of Sir William Thomas Lewis and to the male side by public subscription. The increased general expenditure involved by this additional accommodation has been met by an annual contribution of 1*s.* from each workman employed in the local collieries and ironworks. The men employed at the Cyfarthfa works have not joined in this general scheme because they maintain that every medical man practising in the town should be *ipso facto* a member of the staff of the hospital. The workmen at the other works contend that the Cyfarthfa men should not have the benefits of the institution unless they comply with the conditions in force elsewhere, and the executive board of the hospital upholds this contention, so that except in cases of extreme urgency the Cyfarthfa men are not received for treatment.

Bristol Pauper Children.

In a city so renowned as Bristol for its philanthropic institutions it is not a little strange that those who are responsible for the well-being of the poorest classes should appear to have so little sense of responsibility when the medical care of the latter is concerned. For some years past the Local Government Board has been urging the board of guardians to provide better and more adequate infirmary accommodation but the recommendations of the central authority have upon one pretext or another been either entirely ignored or postponed. At the last meeting of the board of guardians but scant courtesy was shown to suggestions made in a report of Mr. Andrew Fuller, a medical inspector of the Poor-law department of the Local Government Board. Mr. Fuller had made an inquiry into the medical supervision of the children under the care of the board of guardians. Some of these children are in grouped homes and others in scattered homes. As regards one of the former, at Downend, it appears that a medical man attends weekly and at other times when required, the superintendent matron being responsible for the decision when these other times shall be. As Mr. Fuller very properly pointed out, this places upon the matron a responsibility which she should not be called upon to bear—namely, the diagnosis of what may be termed minor ailments. The two most prominent recommendations made by Mr. Fuller had reference to the necessity for periodical examinations of the children's teeth and an examination by a specialist of the naso-pharynx of every child in the homes with a view to ascertain the necessity for medical or surgical treatment. Mr. Fuller stated that he found several children with badly ulcerated gums owing to their teeth requiring attention, while others had had their first teeth extracted, and none of the carious teeth of any of the children had been stopped. He also pointed out that quite a large proportion of the children were suffering from conditions of the nasal passages which required surgical or other treatment. In spite of these very precise statements from so experienced an official as Mr. Fuller his recommendations were spoken of by members of the board of guardians as "absurd" and "monstrous," mainly apparently because they involved additional expenditure. They do not seem to realise that nothing is more wasteful than to send out into the world from their schools youths and girls handicapped with deafness and the other untoward results of adenoid growths, and with their teeth so decayed that their digestive functions are seriously impaired.

From Medical Officer of Health to Medical Missionary.

Dr. Peter Fraser, the medical officer of health of Carnarvonshire, has just applied to the Calvinistic Methodist Foreign Missions for an appointment as medical missionary in the Khassia Hills, India. It is expected that his application will be accepted and that his wife will share in his work. Dr. Fraser has made great efforts for the improvement in the housing of the working classes and has been instrumental in the removal of large slum areas in Carnarvon.

Sept. 10th.

of polylobular fibrosis of the liver, but that various causes, including alcohol, may lead to a condition favouring the action of some toxic agent, whether chemical or bacterial, which is the actual cause of the condition. In any case, it is wise to be extremely cautious in suggesting that the cause of a cirrhosis in a child is due to the taking of alcohol, as the history of the above case demonstrates.

* No trustworthy average.

All the above figures, excepting those for Sandown, have been computed from the reports published daily or weekly by the Meteorological Office, and it is therefore permissible to suppose that they represent accurately the temperature, rainfall, and bright sunshine of the past summer at the various observing stations. It will be seen that the mean temperature for the three months was everywhere below the average, the defect ranging from about two degrees to four degrees. The absence of heat was generally much more marked during June than during the two subsequent months, but throughout the whole period there were extremely few afternoons with an average temperature for the time of year. Most of the nights were also cold, but as a rule the divergence from the normal was less after sunset than during the daytime. The daily range of temperature was consequently considerably smaller than is usual in summer, and this fact probably accounts to some extent for the generally low death returns. But there were other elements which also tended to render the weather of the summer more than usually favourable to health, and if a meteorologist were asked to give his opinion he would probably say that besides the equability of temperature the other contributing causes were (1) the very frequent slight falls of rain that had such a cleansing effect upon the atmosphere, and (2) the relatively great velocity of the wind, which prevented the air becoming stagnant in the large cities. One of the chief features of the season was, indeed, the very large number of days when the wind from some point of the compass between west and south blew strongly or briskly. The air was thus never allowed to rest, but a pretty constant fresh stream was always arriving from the broad Atlantic. Under such conditions a summer is certain to be cool in this country, just as a winter cannot help being mild. In the summer the air has no time to be warmed by radiated heat from the earth and in winter it is in too great a hurry to be cooled from a like cause. Shade temperature readings of 70° and above were remarkably rare. In London (Westminster) there was only one in June, nine in July, and 12 in August, and the highest temperature of the whole year at the same well-exposed station was not during summer at all, but on May 12th, when the thermometer rose to 79°. Days with more or less rain were very numerous, but except in the north and north-west and in a few scattered localities elsewhere the aggregate fall was small. Nearly everywhere July and August were dry, the heavy amounts in the north-west being the result of a wet June. The driest spots were in the extreme east of England and at the Scilly Isles, Lowestoft having no more than 3·4 inches and the Scilly Isles only 3·5 inches. In the extreme south-east only about one day in three was rainy, while in the north-west there was only about one day in three without rain. Sunshine, like temperature, was below the average throughout the entire kingdom, but in several localities the deficiency was very small. At Eastbourne it was not more than 14 hours, at Blackpool 17 hours, and in London 26 hours. Omitting the large aggregate of 669 hours at Sandown, the records of which were presumably not examined by the Meteorological Office, the sunniest place given in the table was Eastbourne with 656 hours, followed very closely by Jersey and Worthing, while the most sunless spots were Manchester and Glasgow, each with 359 hours. These two populous cities received less than four hours' sunshine per day, while Eastbourne enjoyed rather more than seven hours and London more than five and a quarter hours per day. The record for London was very satisfactory, its total of 489 hours being only 20 hours less than that at Llandudno, 60 more than at Birmingham, and 27 more than at Harrogate. During the corresponding period of 1906 the metropolis recorded 693 hours and the number of hours at Torquay, Bournemouth, Clacton, and several other resorts on the south and south-east coasts exceeded 750.

FATAL HÆMORRHAGE FROM THE JUGULAR VEIN IN CHRONIC OTITIS MEDIA.

IN the *Boston Medical and Surgical Journal* of July 4th Dr. F. L. Jack and Dr. F. H. Verhoeff have reported a case of chronic otitis media which terminated in an unusual manner—by fatal hæmorrhage from the jugular vein. A girl, aged two and a half years, was taken to hospital. She had been in good health until two weeks previously, when she became fretful and evidently was in pain. A swelling had been noticed behind the right ear for nearly a week and a discharge of pus from the ear for several days. There was much coagulated blood in the meatus. Over the tip of the mastoid, extending about one inch below and one and a half inches posteriorly was a large, tender, and fluctuating swelling of the size of a Tangerine orange. The child was admitted and two hours later severe hæmorrhage occurred from the mouth and nose. When the house surgeon patients under treatment, with 121 discharges and 94 deaths. The admissions show a decrease of 55 as compared with the previous year, the diminution being due to a falling-off in the cases transferred from the Belfast workhouse (the numbers from that institution being fewer by 59), while, on the other hand, the number of admissions directly from the patients' homes remains at the same ratio to the population as in previous years. In a very interesting and suggestive report Dr. Graham quotes from the inspectors of lunatics in their special report (on the alleged increase of insanity for 1906) a statement to the effect that they believe that "the Irish branch of the Celtic race is specially predisposed to mental breakdown, and therefore the great increase in the number of registered insane all over the civilised world is for this as well as for other reasons very marked in Ireland"; and they think that probably "the innutritious dietary and other deprivations of the majority of the population of Ireland must, when acting over many generations, have led to impaired nutrition of the nervous system, and in this way have developed in the race those neuropathic and psychopathic tendencies which are the precursors of insanity." Further, statistics prove—as stated in Dr. Graham's report—that the proportion of the insane among the Irish in America is greater than that of any other nationality. It is curious that Armenian and other emigrants to the United States from the Turkish dominions do not evince the same proneness to mental breakdown. Further, the refugees from Poland and from some parts of the Russian empire (whose state at home has been as unhappy as the Irish emigrant) do not show the same tendency to mental breakdown. Dr. Graham suggests, as an explanation of this curious fact, that it is due to two reasons. First, that many Irish emigrants are driven by poverty to the United States who are ill-fitted for the new conditions of life, the crowded tenements of big cities, and the abnormally keen competition for a livelihood—in a word, all that is implied in a sudden change from a quiet agricultural existence in Ireland to the bustle and excitement of New York or Chicago; and secondly, that the intellect of the Irishman is finer and that he is more civilised than the Russian or Hungarian. Owing to the fact that the Irish race, as a race, is of finer psychical structure, therefore, adverse conditions tell on him more strongly than on the others. This brightness, to quote from Dr. Graham's report, this keen susceptibility to joy and sorrow, make him more liable to mental breakdown than would be the case among duller peoples. The gross expenditure for the financial year ended March 31st, 1907, amounted to £25,483, which, after deducting receipts from paying patients and miscellaneous sources, gives the low net capitation cost of £21 1*s.* 8*d.* per annum. Special reference is made to the great loss which the institution—and, I may add, the medical profession—has sustained in the death, on Feb. 13th, 1907, of Dr. R. A. L. Graham who had been an assistant medical officer for eight years. Dr. A. S. Merrick, who for 22 years was medical superintendent (he resigned in 1897), died at the close of last year.

Queen's College, Belfast.

The report of the President of Queen's College, Belfast (Rev. Dr. Hamilton), just issued for the academic year, 1906–07, indicates that the College continues to prosecute its work with vigour and success. Special reference is made to the splendid achievement accomplished by the equipment fund. 20 years ago there was but one laboratory; now there are eight. Owing to the Treasury giving £5400 for new buildings on condition that a corresponding sum of £5400 was contributed by the better equipment fund, there are now the "Donald Currie Laboratories" devoted to chemistry, the "Musgrave Laboratories" devoted to research and teaching in pathology and bacteriology, the "Jaffé Laboratories" for physiology, the "Harland Laboratories" for natural philosophy and engineering, as well as biological, pharmaceutical, and anatomical laboratories. Of the students there was an increase in the Faculty of Arts and as usual the medical students were numerous. An athletic field will be available next session, and all the students' college societies appear to have had very useful and successful sessions during the academic year 1906–07. Among the honours to old students Professor J. W. Byers was knighted, Serjeant Dodd, K.C., was appointed one of His Majesty's judges in Ireland, and Mr. J. O. Wylie, K.C., was selected as the judicial head of the Irish Land Commission.

Women's National Health Association of Ireland.

Her Excellency the Countess of Aberdeen is to be present and to take part in a meeting which will be held on Oct. 29th in the City Hall, Belfast (the Lord Mayor, the Earl of Shaftesbury, presiding), to establish a Belfast branch of the Women's National Health Association of Ireland.

Lunacy in Ireland.

The following deplorable statistics were mentioned at a meeting of the Belfast Asylum Committee on Sept. 9th. In 1851 the registered number of insane in Ireland was 9980; in 1901 they totalled 25,050, or 1 to every 179 of the population. In 1851 the entire insane for Belfast, county Antrim, county Down, and Carrickfergus was 330. The last returns showed—Belfast, 1150; County Down, about 600; and County Antrim, about 550; a total of 2300, or an increase of 1970. While the population of Ireland in 1841 was 8,175,124, it was in 1901 4,458,775, a decrease of 3,716,349. (In 1906 the Registrar-General estimates the population as—in the middle of the year—4,388,006, while in 1906 there were 35,344 emigrants.) Comparing the number of lunatics per 10,000 of population, the result was:—

	England and Wales.	Scotland.	Ireland.
1871	30·4	34·0	30·5
1881	32·5	38·5	35·6
1891	33·6	38·4	45·0
1901	40·8	45·0	56·2

Such startling figures surely demand the attention of statesmen and patriots.

Cerebro-spinal Fever.

On Sept. 9th a boy, six years of age, who first exhibited signs of cerebro-spinal meningitis on Sept. 6th, died at Harryville, Ballymena, county Antrim.

Sept. 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Purification of Water in Hotels.

THE French Touring Club is organising a competition the object of which is to discover the best means of insuring the purity of water supplied in hotels. The programme has been arranged by a committee of which M. J. Lucas-Championnière is the president, and proposals are invited for methods of sterilisation which will be satisfactory alike to the Faculty of Medicine, to hotel-keepers, and to travellers. Any inventor may compete. The method or apparatus which is adjudged the best will be recommended to all hotel-keepers and to all the members of the French Touring Club.

Vaccination in Paris.

Dr. Roux has presented to the council of public health of the department of the Seine a report on his inspections of vaccination stations (*établissements vaccinogènes*) in 1906. He remarks that he cannot conclude his report without calling attention to the fact that more than three years have elapsed since vaccination and revaccination were made obligatory, but that the law has not been systematically enforced either in Paris or in the department of the Seine. Lists of persons who were required to conform to the regulations were not prepared, hours of attendance (*séances*) were not arranged, and the results were not recorded.

The School of Medicine in Indo-China.

In the School of Medicine at Saigon in Indo-China a military department has been established for the purpose of training ten native medical assistants each year. The students will be selected by competition among the native soldiers in course of training. The period of study will be four years.

Treatment of Ankylosis of the Knee joint with Malposition.

At the congress of the French Association for the Advancement of Science M. Lardennois read a paper on the treatment of the cases in which a child's knee joint had become ankylosed in a faulty position. He said that ankylosis of the knee-joint in the position of flexion was not uncommon in children, and the proper treatment was a difficult problem because the same operative measures could not be used as in radial artery of the patient's brother-in-law. This raised the red corpuscles from 1,270,000 to 1,800,000. In the evening the patient was flushed and lethargic and perspired much. The temperature was 102°. On the 29th he was very jaundiced. The temperature rose to 104°. The arms were painful and swollen and the hands were œdematous. The liver increased in size and became tender and the spleen was palpable. Petechiæ appeared. The urine contained urobilin, hæmoglobin, blood, and many casts. After the first transfusion the urine became slightly reddish and contained a little urobilin, suggesting hæmolysis, but this condition had nearly disappeared at the time of the second transfusion. During the night after the second transfusion the urine became bloody and subsequently its condition showed a direct relation with the jaundice, oppression, and other evidences of hæmolysis. On April 30th the jaundice was worse, the temperature was still high, and the mouth was very dry but not bleeding. Death occurred on May 3rd. The necropsy showed numerous small pulmonary hæmorrhages, dilatation of the heart, and acute parenchymatous nephritis with subcapsular ecchymoses. The cases reported by Dr. Crile seem to show that direct transfusion is a safe procedure in hæmorrhage. But the present case indicates that there may be danger of *hæmolysis* in certain pathological conditions.

HYPERSUSCEPTIBILITY AND IMMUNITY.

THAT nothing in nature is too trivial to be worth recording is now a commonplace of science. Light is often shed on important problems from the most unexpected quarters. An instance may, perhaps, be seen in some recent researches carried out by Dr. M. J. Rosenau and Dr. J. F. Anderson on the somewhat obscure phenomena of hypersusceptibility[1] produced in animals by injections of foreign serum. The observation upon which these studies were based was the discovery that if an animal were injected with a dose of horse-serum and subsequently received a second dose of the same after some days' interval serious and even fatal symptoms were produced. From further experiments it appears that the same phenomenon results from the injection of other albuminous substances, such as white of egg or even extract of yeast, and that an interval of about ten days must elapse before the condition of hypersensibility is fully developed. This condition is transmitted by the mother to her offspring but not by the father. The administration of uncooked meat results in the production of some degree of susceptibility to the albumins of the animal eaten, but this result is prevented by thorough cooking of the meat. The explanation of the phenomenon is not very clear, but "profound chemical changes, perhaps in the central nervous system, are probably produced by the first injection of a strange serum." The interesting suggestion is made by the writers that the incubation period of an infectious disease—often a period of about ten days, corresponding closely with that needed for the production of hypersusceptibility—may be explained by the existence of some similar action, while the analogy with the phenomena seen after injection of tuberculin is obvious. The still more curious feature seen in some diseases, the occurrence of a crisis, may perhaps prove to come under the same law. These observations have also a bearing upon the production of immunity, the writers holding that a condition of hypersusceptibility is probably necessary as a stage in the production of immunity to one class of diseases. It corresponds to some extent with the "negative phase" or diminished resistance seen after inoculation with bacteria or their toxins. Thus hypersusceptibility produced in guinea-pigs by extracts of some varieties of bacteria (typhoid, colon) was followed by a definite immunity to the corresponding infection but this was not the case with the bacilli of anthrax.

TRADE CUSTOMS.

THE term "trade customs" in some quarters appears to be the modern synonym for malpractices. So many defendants shelter themselves, or attempt to shelter themselves, behind the plea of trade custom that it would be interesting to have a list published of "trade customs." The public have a right to know what trade customs are. We doubt very much if the public know quite so much about them as the trade. Police-court proceedings enlighten us considerably at times, but there are so many "trade customs" that we plead for a glossary of them. We fancy that we should be fairly safe in saying that such a compilation would open our eyes to a string of petty practices designed more or less to cheat the purchasing public: trade customs, in fact, which though approved by the trade are, strictly speaking, illegal transactions. We should like to see appointed a Royal Commission on "trade customs." The selection of the Commissioners, who, of course, would be authorities on the subject, would be interesting and the evidence of the witnesses would at least be amusing if not instructive. The final report would have the word "swindle" written in every one of its conclusions—that is to say, if the Commissioners honestly set about their business. These may be strong words, but day by day we read in police-court proceedings how indictment after indictment is met by the sickening excuse of "trade customs." Brown paper is found in the soles of boots; it is a trade custom. Silk containing cotton is sold as pure silk; it is a common practice of the trade and therefore a justifiable one, because the trade recognises it. It is also at times the trade custom to call an article brandy which is not brandy, soda-water which is not soda-water, butter which is not butter, and so on *ad infinitum*. In fine, it will be found that "trade customs" as a rule do not call a spade a spade and things are not what they seem. The term "trade customs" is a cloak, is not in many instances honest, and in an equal number of instances exists to evade the law. The law should recognise no trade custom which is not straight dealing.

THE FREQUENCY OF THE BABINSKI SIGN IN GENERAL PARALYSIS.

Dr. Alfred Gordon contributes an interesting paper entitled "A Study of Reflexes of the Lower Extremities in 60 cases of Paresis" to the July (1907) issue of the *Journal of Nervous and Mental Disease* (America). He refers to the general agreement by most authorities that the Babinski sign is rarely present in cases of general paralysis. Robert and Fournial (*Revue Neurologique*, Nov. 21, 1906) reported that out of 66 cases of paretic dementia they had only found it present in one patient. As Dr. Gordon states, the reason for this infrequency is not easy to explain when it is borne in mind that the involvement of the motor tract in general paralysis is the rule and further that the Babinski reflex is unquestionably a sign of an involvement of the motor pathway in its central or terminal ends. Dr. Gordon showed in his first clinical studies[1] that the "paradoxical reflex" is "a sign of irritation or early stage of a lesion of the motor tract," and he considered that it would be of some pathogenetic value to study the relationship of this reflex and the Babinski sign in general paralysis. He refers to Wyruboff's work in the *Revue Neurologique*, 1900, in which he showed that, from the anatomico-clinical standpoint, all cases of general paralysis can be divided of the University of Turin, where he is professor of psychiatry and criminal anthropology, and who (*si quis alius!*) is a witness of the evils of the abuse of alcohol, speaks with less confidence on the subject and would advise abstention from the beverage wherever it "is impossible to fix the dose beyond which it becomes a source of the more serious mischief;" and a no less distinguished psychiatrist, Professor Enrico Morselli of Genoa, sees the root of the evil not in wine but in "the alcohols of industrial origin." Professor Capparelli, who holds the chair of physiology in the University of Catania, agrees with his *confrère* Morselli in insisting on pure wine culture and traces the harm done by "alcohol" to the artificial products thrown on the market, adding: "I believe the moderate use of sound wine to be an excellent coefficient of health," while he scouts the notion that taken thus it can ever cause hepatic mischief. Dr. Carlo Ruata, professor of materia medica in the Umbrian School (University of Perugia), maintains that a truly scientific and impartial investigation of the whole subject has yet to be started and sides with Capparelli in announcing that the moderate use of wine has never caused cirrhosis of the liver. The professor of hygiene at Naples, Dr. De Giaxa, thinks that the use of vinous beverages is a question of individual tolerance and cannot persuade himself that sound wine is not "good for digestion and the physical energy of the organism." Professor Alfredo Rubino (also of the Neapolitan University) is equally emphatic in favour of the judicious use of wine, as are also Professor Sanfelice of Messina and Professor Martinotti of Bologna. Professor Antonio Carle of Turin, who, as a pure surgeon, disclaims all pretension to speak with authority on a medico-clinical question, approves the moderate use of alcohol freely diluted; of the same school, Dr. Bernardo Silva, though an abstainer of ten years' standing, admits the benefit of graduated doses of wine, especially in fever cases and in convalescents; and Professor Galeotti of the Pathological Institute of Naples, after he had long been a teetotaler, began the graduated use of fermented liquors in convalescence from illness and found distinct benefit from it. Lastly, Professor Mangiagalli, the distinguished successor of Porro in the Lombard School, deprecates the "exaggeration" which is a distinctive note of the total abstinence propaganda. "I have even read in books," he says, "a denunciation of bread. There are certain men of science, like the mediæval Mystics, who would mould and model a humanity naked, joyless, subsisting on fruit and water. The crusade against alcohol is holy, but it can gain neither in force nor in effect by making itself the mouthpiece of assertions and exaggerations demonstrably unscientific." 18 representatives of Italian medicine, it will be seen, have each, *ex cathedrâ* and, so to speak, above his own signature, pronounced opinions on the moderate use of wine, and in well-nigh every case, some more, some less, emphatic in expression, have declared in its favour. Wine, not spirits, the juice of the grape *par excellence*, as consumed in Latin countries, is the beverage under consideration, and there is unanimity among the 18 medical men as to the wine trade having itself to blame if by impure production it plays into the hands of those who would eliminate all wine, good as well as not so good or positively bad, from human consumption. One of the 18 anticipates a reaction against the mineral waters now so common as a substitute for the "bottled sunshine" of his native land. In these, too, it is alleged, there is spurious manufacture! But, when all is said and done, the public have nothing to lose by discussions which make for the production of a genuine article and for the use of the said article in moderation.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Birth Returns.

THE Imperial Medical School of Haidar Pasha on the Asiatic side of the metropolis has submitted a very useful suggestion to the Ottoman Ministry of Justice, as well as to the central municipality, with regard to the necessity of registering in a constant and regular way the birth returns of Constantinople. Up to now only deaths were recorded, whereas the returns of births were utterly neglected. This neglect rendered the accurate making of the census and the ascertaining of the actual increase or decrease of th indigenous population impossible. True, there existed th practice of registering the births by imams and mouktar as well as by the officials of non-Mussulman religious communities, but this was done in a very incomplete, negligen fashion, the returns never being submitted to the municipalities. Henceforward it is intended to remedy this stat of things. Orders have been given that each municipality is to provide a general official register for the purpose o entering birth as well as death returns. The municipa sanitary inspectors will be responsible for the regular and accurate registration. It will thus be possible in the futur to compare the death- and birth-rates and to make correc statistics of the movement of the population.

Yaghourt and its Adulteration.

One of the chief popular foods in Turkey is yaghourt This is a kind of curdled milk which makes a very favourite dish in spring and summer time, especially with the poorer classes of the population. At present there exist six factories which supply the metropolis with yaghourt; two at Epivatis, one at Tcheuplidé, and three at Callictaria. The one at the last-named place, in possession of a Moslem, is the largest and best equipped. It is a stone building and has three large boilers of 600 litres capacity each. The milk used in this factory is that of the sheep. This is boiled for two hours, being at the same time agitated, and then poured from a considerable height into numerous receptacles which are made of tin and placed upon tiers of slightly heated shelves. Here it is left for two or three hours. The scum is then taken off and rennet introduced for coagulation and fermentation. Now, it has been found that the yaghourt is frequently adulterated, extraneous matter, such as flour, or starch, or gum, or other oftentimes injurious ingredients, being introduced into the milk kept for its preparation. This fraudulent practice will now be strictly forbidden and severe measures taken to insure that all the yaghourt factories, and the local dairies where this food stuff is being prepared on a minor scale, shall produce pure, unadulterated yaghourt. The municipal medical men will visit at regular intervals the factories and the dairies. They will also examine the dishes and receptacles of hawkers selling yaghourt in the streets. Every fraudulent practice will be heavily punished.

The Cholera.

Extensive and energetic measures are being taken against the dreaded invasion of cholera from Russia. In that country the scourge seems to make great ravages, judging from the reports received in Constantinople. It is spreading through many provinces and has reached even St. Petersburg. The Red Cross Association of that city has granted 100,000 roubles for the purpose of combating the epidemic. This association also sends a number of medical men to every infected district, while medical committees hold frequent meetings for the discussion of means and measures of prevention and cure. The government of Samara seems to suffer most but Simbirsk, Astrakhan, and Sisran are also suffering greatly. One valuable measure is the erection of tea houses, thus enabling the populace to dispense with the use of unboiled river water. It is to be hoped that the steps taken in Constantinople will prove to be efficient, but at any rate the Conseil Supérieur de Santé is exhibiting a laudable vigilance.

August 23rd.

VACCINATION FEES IN SOUTH WALES AND THE WEST OF ENGLAND.—At a meeting of the Neath (Glamorganshire) board of guardians held on Sept. 4th it was decided to pay the minimum vaccination fees to the public vaccinators.—At a meeting of the Warmley (Gloucestershire) board of guardians held on Sept. 3rd it was decided to give the minimum fees for vaccination to the public vaccinators of the union, one of the guardians remarking that "he was sorry they could not make it lower as he did not believe in vaccination."—The public vaccinators of the Bristol union have accepted the fees for vaccinations as suggested by the guardians. Seven of the public vaccinators consequently will receive the minimum fees allowed by the Local Government Board and the remaining two gentlemen will receive 3*s*. 6*d*. and 4*s*. per case respectively, owing to the larger area and more scattered population of their districts.

from his observations. It may be induced by the initial rise of pressure, though the effects are not visible till this has passed off, or it may be caused by some retraction of the blood stream in the veins. Manifestly the question is not yet settled, though all observers seem at one in assuming an alteration in the cells constituting the walls of the capillaries —a view which appears to bring passive effusions into line with those due to inflammation, the change being possibly one of degree, not of kind.

DEAF CHILDREN IN ELEMENTARY SCHOOLS.

A DISCUSSION of some importance took place in the ninth section of the recent International Congress on School Hygiene with regard to the arrangements to be made for children suffering from defects of hearing. Dr. J. Kerr Love recommended that those who were merely "hard of hearing" and some of the better cases of the semi-deaf should be taught in special classes in the ordinary schools. Worse cases, including the intelligent deaf-mutes, should attend special day-schools or oral residential schools, while those deaf-mutes who proved failures in oral classes and those of defective intelligence should have manual alphabet teaching in a residential institution. Mr. P. Macleod Yearsley laid stress upon the difficulties of making ignorant or indifferent parents provide the necessary medical treatment for their children who suffer from ear disease and advocated the passage of special legislation to deal with such cases. If this were impracticable he would institute lectures to parents on aural defects and appoint officers to deal with the careless and refractory. After a discussion on papers read the section unanimously resolved that it was desirable to provide special classes for those deaf children who could most suitably be taught in a "hearing environment," under the control of teachers qualified to teach articulation and lip-reading to the deaf, the classes to be subject to special legislation dealing with deaf children. Certainly nothing but good can come of the efforts of the Congress to call public attention to the needs of these sufferers and from full discussion of the problems involved in their education. Difficulties will almost certainly arise in many schools as to provision of separate class-rooms for deaf children, for it seems scarcely possible to give them their lessons in the same room as other classes. It would be necessary to group the schools in some way, so that the special classes could be held at convenient centres. This, however, is only a matter of organisation and presents no particular difficulty. The training of the necessary number of qualified teachers will further have to be arranged.

RUPTURE OF A BRONCHUS.

IN THE LANCET of Sept. 7th, p. 694, appeared an account of a case which was under the care of Mr. W. H. Bowen in the East London Children's Hospital, Shadwell, and which was recorded by Dr. W. Norman May. The patient was a boy, 15 years old, who had been injured by the wheel of a van passing over his head. He was found to have a double depressed fracture of the skull and pneumothorax. The skull lesion was treated and it was apparently doing well, but the boy died 26 hours after the accident from the thoracic condition. At the necropsy it was found that the right bronchus had been torn completely across immediately below the bifurcation of the trachea, the torn ends being separated about half an inch. There was no blood in the pleural cavity and the ribs, clavicles, and pleuræ were quite intact. Complete or even partial rupture of a bronchus is a very rare condition and when it does occur it is nearly always associated with, and due to, fracture of a rib or the sternum, the sharp edge of the broken bone being the direct cause of the rupture. In the case above mentioned, which Dr. May has described, all the ribs were intact and therefore this explanation is inadmissible. A possible explanation is that the chest was much compressed by the heavy wheel of the wagon, and then the pressure on the lung forcibly tore it away with the bronchus from the trachea. Mr. A. Marmaduke Sheild exhibited a specimen at a meeting of the Pathological Society of London on March 19th, 1889, showing complete rupture of the left bronchus. A man, 47 years old, was crushed between the pole of a van and a wall. In addition to other injuries to the chest the third and fourth ribs were broken and the left bronchus was torn completely through close to its junction with the trachea. In this case it is probable that the bronchus was torn by one of the broken ribs. It is curious that so little is to be found in the text-books relating to this rare though important lesion, and though specimens are to be seen in several museums very few histories are obtainable.

EPIDEMIC CEREBRO-SPINAL FEVER.

AT the annual congress of the Incorporated Sanitary Association of Scotland, held at Aberdeen on Sept. 5th and 6th, a discussion on epidemic cerebro-spinal fever was opened by Dr. A. K. Chalmers, medical officer of health of Glasgow. Dr. R. M. Buchanan, bacteriologist to the Glasgow corporation, read a paper on the Examination of Cerebro-spinal Fever Contacts. He said that the meningococcus existed in the naso-pharynx of a large proportion (26·3 per cent.) of the healthy persons who had been in close contact with cases of the disease and that such persons, acting as carriers of the meningococcus, provided a very large source of potential infection. Dr. W. Leslie Mackenzie said that during the last six months 1611 cases had been reported to the Scottish Local Government Board and that 648 of these were in Glasgow. In Scotland during the week ended Sept. 7th there were eight deaths from this cause registered in Glasgow and one in Edinburgh. In Belfast during the same period there were five deaths registered as being due to this cause.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Sept. 6th states that for the week ended Sept. 5th there were 5 cases of plague and 4 deaths from the disease. As regards Hong-Kong, a telegram from the Governor received at the Colonial Office on Sept. 9th states that for the week ending Sept. 7th there were 5 cases of plague and 5 deaths from the disease. The department of public health of Queensland, in a bulletin dated August 3rd, states that no case of plague had occurred in Brisbane since July 26th. As regards the Cape Colony, the medical officer of health for the colony states that for the week ended August 17th no case of plague occurred in King William's Town or district.

THE tablet to the memory of the late Robert Barnes, M.D. Lond., will be unveiled in the Robert Barnes Laboratory of St. George's Hospital at 3.45 P.M. on Tuesday, Oct. 1st.

POLLUTION OF THE RIVER YEO.—At a meeting of the Yeovil rural district council held on Sept. 2nd a report of a series of analyses by the county analyst (Dr. H. J. Alford) of samples of water taken from the river Yeo below the outfall from the Yeovil corporation's sewage works was read. The report indicated that the stream was largely polluted with sewage and one sample contained arsenic in appreciable quantity. Arsenic is used in the preparation of the leather for the glove manufacturers. After some discussion the chairman said he did not see that the council could do anything at present in the matter and added "that the Yeovil town council were at their wits' end over the pollution of the river."

admirable exposition of the beliefs and practice of British surgery.

In 1875 he published his well-known "Treatise on the Principles and Practice of Surgery," which, although founded on the "System of Surgery," presented evidence of the personal experience of the author, of his learning as a skilled anatomist, and of his assimilation of the developing doctrines of asepsis. This was the handbook of several generations of medical students in every English-speaking medical school, and indeed has only of recent times been excluded from the list of manuals which it was our custom to recommend for the constitution of a student's library. It was admirably written and illustrated, but not quite as easy reading as it seemed. Holmes's classical culture made it impossible for him not to write clearly, but he was in many places too intellectual for the audience which he supposed himself to be addressing, so that the sequence of events or the force of arguments which appeared clear to him often required more elaboration if they were to be equally clear to the average medical student. The book, however, was a great performance and deservedly enjoyed its popularity. He produced four editions of the work but the fifth edition was left to Mr. T. Pickering Pick, his colleague at St. George's Hospital. Mr. Pick exercised a free hand, for although he preserved the original plan of the book he revised it most carefully, incorporating in it all the recent teaching in surgery and pathology, and especially giving prominence to the innovations in practice and in range of treatment due to the developments of aseptic surgery.

The "Treatise on Surgery" and the articles in the "System of Surgery" comprise most of Holmes's literary work, but the appendix on "The Surgical Treatment of the Diseases of Childhood" was extended in scope and detail until it became an important volume when it was published as a separate work and obtained great success, running through two editions and being translated into French and German. His allotment to himself of this subject when bringing out the System was due to the fact that he had been elected in 1859 assistant surgeon to the Children's Hospital, Great Ormond-street. He became full surgeon to the institution two years later and only severed his connexion in 1868 when he became full surgeon to St George's Hospital and also dean of the medical school. Holmes was also the editor for several editions of "Gray's Anatomy"; he translated from the German Wagner's work on "The Resection of Bones," and contributed to the Reports of St. George's Hospital. All the productions of his pen possessed the same qualities of culture and thoroughness, as his not infrequent contributions to our columns show.

As a surgeon Holmes came at rather a difficult period, being about 20 years younger than Brodie, ten years younger than Paget, but a whole generation older than, for example, Macewen, Watson Cheyne, and Treves. He recognised the enormous value and significance of the work of his great contemporary, Lord Lister, but it was impossible for him to do more at once. Lister had taught himself, and was instructing the whole scientific world junior to him, but no one could have taught Lister's contemporaries who had left the lecture-room too long to become flexible pupils when the famous work at Glasgow and Edinburgh began to bear results as a complete revolution. Holmes had been brought up in an older school, and though he faced manfully the difficulties of an entirely new technique, and though he was insistent upon the Listerian doctrines in his lectures, he never became a great exponent of the practice of aseptic surgery. He was, however, a bold and fertile operator and records of his work in the two hospitals with which he was connected form a remarkable tribute to his mastery of his science, while he welcomed the teachings of aseptic surgery in the most whole-hearted manner because of the vastly extended scope of operative treatment which it promised. The last paper which he contributed to our columns[1] is a splendid testimony to his foresight as a surgeon, as well as to the long continuance of his skill as an operator and his adaptability towards modern methods. In 1875, in the first edition of the "Treatise on the Principles and Practice of Surgery," he had advocated that the right treatment for rupture of the bladder was abdominal section and the immediate suture of the rent. The teaching was in advance of the day, the leaders of surgery being still unaware of the possibilities opened up to them by aseptic technique, and though it was adopted b the late Mr. C. Heath and Mr. A. Willett, and possibly b one or two others, the results were not satisfactory. Bu in 1886 Sir William MacCormac recorded in our column two successful cases of suture of the ruptured bladder afte abdominal section, mentioning the fact of Holmes's early advocacy of the procedure; and in the following yea Holmes had the gratification of being able to record a successful case under his own care. The details which he published show that he had foreseen in days when the operation was considered to be but a desperate remedy in a desperate plight, the difficulties that would have to be met by the surgeon, and that he recognised, when at last the opportunity came to him, the advantages of the Listerian technique.

As a teacher he possessed virtues which made him a little dreaded though enormously admired by the students at St. George's Hospital for over 30 years. He was clear, forcible, sarcastic, not unkind, but distinctly intolerant of fools. The scholar and the logician in him would forgive slowness if it was redeemed by patience, but he could not abide shallowness and glibness. The student who attending at a test examination had committed to memory from Holmes's own book a list of signs and symptoms would find his complacency rent from him by an inability to answer one or two questions on first principles. He used the same methods during the years when he was an examiner at the Royal College of Surgeons of England, and many are the men who attributed their failure to his alleged severity. As a matter of fact he was not severe, for the well-grounded candidate always had in him a friend. He could not forgive pretence, but he was always quick to mark the man whose knowledge was ahead of his powers of expression.

As a man of affairs Holmes was a great success, his clearness of vision, his personal courage and integrity, and his habit of hard work enabling him to detect the reasons of failure as well as to appreciate the factors of success. His experience of hospital affairs made him an authority upon the numerous practical and social questions which centre round what is known as hospital abuse. Jointly with the late Dr. J. S. Bristowe he was the author of a valuable report on hospitals to the Privy Council (Sixth Annual Report to the Medical Officers of the Privy Council). More than 20 years ago he pointed to the development of provident dispensaries, so that they might form a link between the general practitioner and the out-patient department of hospitals, as the right step to be taken to protect alike the charitable contributions of the well-to-do, the rights of the sick poor, and the position of the professional man. That in such development lies probably the solution of a most difficult problem is now an accepted belief. As treasurer of St. George's Hospital he exercised for more than a decade a close supervision over the work of the institution with which he had been so long connected. He was for 20 years chief surgeon to the Metropolitan police, he filled the distinguished post of President of the Royal Medical and Chirurgical Society, and he sat with advantage to his colleagues upon many committees to consider questions of hospital dispensation.

We have said enough to justify our earlier statement that Timothy Holmes, though of late fallen out of the line of observation, was one of the great figures of Victorian surgery. He was publicly accepted as such. To members of the St. George's Hospital Medical School during the long years of his active work he was always the personification of the great surgeon. His wide reading and extensive and accurate scholarship—for to his attainments as surgeon and anatomist, classic and mathematician, he added a knowledge of French and German—his devotion to his work, his caustic simplicity, his dignified appearance and the mannerisms due to the fact that he had lost the sight of one eye will always dwell in the memory of his pupils. To have been Holmes's house surgeon or Holmes's dresser meant the lifelong recollection of Holmes's characteristics. To have been his colleague was equally to feel his influence, as the following brief communication shows: "By his colleagues," writes "W. H.," "Mr. Holmes will be mourned with affectionate sorrow as one who was ever an example of the highest integrity and the most disinterested generosity. By his juniors he will be remembered with especial gratitude as always ready to help them with his advice and experience and to place at their service his unrivalled knowledge of the literature of his profession. He was, moreover, particularly careful of the only imposed fines of 1*s.* Such noisy nuisances as those complained of are at least as disturbing to those who are awake and are doing their day's work quietly without annoying their neighbours as they are to persons who desire to rest, and it is to be regretted that in a city like London where a certain amount of noise is inevitable wholly unnecessary additions to it should not be more vigorously repressed than they are.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 12th, 1829.

ADVICE FOR THE PREVENTION OF FEVER IN IRELAND.

To the Editor of THE LANCET.

SIR,—Observing at page 657 of THE LANCET, a few simple and excellent rules recommended at the London Fever Hospital to be adopted to prevent contagion, I take the liberty of enclosing you some rules of a similar nature with which I have lately met, issued a few months since from a fever hospital in Ireland. You will not only render a service in Ireland, where your journal circulates very widely, by republishing them, but you will both amuse and instruct many of your readers in this country, by the insight which this "advice" thus unpremeditatedly affords them, into the degraded state of the lower class of people of that country. We may readily judge what must be the state of health in those neighbourhoods in which it is necessary to advise the people "to scrape their floors with a *spade*, and sweep them every day" Houses without windows and chimneys, floors matted with dung, spades instead of brooms, straw beds, and foulness of all kinds, seem the common characteristics of that unfortunate country. Well might Dr. Stoker, in speaking of its poorer classes in his report, have said that "Their habitations were ruinous, and their apartments (into each of which numbers crowded, in order to lessen expense, by dividing the cost of rent and taxes) became so many laboratories of noxious vapours, sometimes more like the neglected cemetries of the dead, than habitations of the living."

I am, Sir, your obedient servant,

London, Sept. 5. G. I.

"*Advice to prevent Fever.*

"Nisi utile est quod facimus, stulta est Gloria."—*Phædrus.*

No. 1.—Let your doors and windows be kept open in the day; if you have not a window in the back part of your house, make one; have them so hung as to be easily opened; have a chimney with a good draught, so as to encourage a free current of air through your house.

No. 2.—Remove dung and putrid matter of every kind, from before and behind your houses, as the vapour and smell proceeding from them, (called malaria,) have been found by physicians to generate infectious fever.

No. 3.—Scrape your floors with a spade, and sweep them every day; also the yards before and behind your houses as often as you can; keep your hair cut short, and comb it every day; wash your hands and face; keep your clothes, furniture, and utensils sweet and clean.

No. 4.—Don't go into any house where a person is sick, or has been ill of fever; don't attend the wake of any person who has died of fever; if you do you will be infected yourself, and will communicate fever to your family.

No. 5.—Don't let strolling beggars enter your houses, as they frequently carry infection from one house to another.

No. 6.—Whitewash your walls, inside and outside, with lime slacked in the house, and while it continues hot and bubbling; let this be done once a month while fever is prevalent.

No. 7.—If fever attacks your family, as soon as the calamity is removed by recovery, or by death, employ the above means as soon as possible; burn the straw of the bed; put all the clothes of the house in cold water, wring them out and wash them in hot water, soap, and pot-ashes; let every box, drawer, chest, &c., be emptied and washed, and let the floor under the patient's bed be strewed with lime fresh slacked and hot. Let no person upon recovery go into a neighbour's house, nor into any public place of worship, for fourteen days.

No. 8.—REMEMBER!!! that cleanliness and good air will improve your health and strength, will check disease, and UNDER GOD will preserve you from all the variety of wretchedness and misery occasioned by INFECTIOUS FEVER.

Valley House.

NOTE!—Heads of families are strongly recommended to have a printed copy of this advice pasted up in their houses, and to enforce a strict observance of its instructions.

The gentry are advised only to give employment to such persons as carefully attend to the rules therein contained.

A strict adherence to this plan constitutes the sole means for removing the principal cause which generates typhus fever in Ireland, viz. the fetid smell (called "malaria") exhaled from vegetable and other substances in a state of putrid fermentation.

It is reasonable to hope, that every other cause will be eradicated by comfortable clothing, wholesome food, and good lodgings, which comforts can only be obtained through the medium of constant employment given to the poor."

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Port of Manchester.—Mr. W. F. Dearden reports that during 1906 powers were obtained for examining imported foodstuffs introduced into the country *viâ* this port, and he furnishes an instructive chart showing the value of food imports entering each of the principal ports compared with the value of total imports from abroad. This chart accentuates not only the enormous proportion of our total imports which is made up of foods but also the great importance of proper control of such imported foods. Powers for the inspection of food imports have been possessed by the Port of London since 1893, but Manchester (the youngest provincial port) has been the first to obtain such powers outside the metropolis. It is interesting to all those who study the problem of our dependence upon outside foodstuffs to learn that during 1905 the value of food introduced into this country through the 13 principal ports more particularly devoted to this trade amounted to £201,722,057 in relation to a sum of £424,320,251 which represents the value of imports of all kinds—i.e., nearly half the money spent by us in imports is for food. As regards the Port of Manchester the actual value of the food introduced *viâ* the Ship Canal has steadily increased from £2,919,825 in 1901 to £5,024,119 in 1905, and all this food is still apparently being admitted without any inspection in the port. The Bill embodying powers for inspection was not inscribed upon the statute book without considerable opposition as it was felt that to place restrictions upon a new and rising port would be undiplomatic as regards the progress of business. It was contended that if the powers in question were to be conferred they should be bestowed on all port sanitary authorities throughout the country. Although these powers have now been obtained as regards Manchester they have not as yet been actively enforced pending the passage through Parliament of general measures conferring similar powers upon all port sanitary authorities throughout the kingdom. We find here, in fact, a further illustration of the value of local Acts in promoting general legislation on the same lines.

Dartford Rural District.—Dr. Sylvester Richmond, as medical officer of health of a rural district in which fruit-growing abounds, finds himself face to face with the two difficult and annoying problems of the control of a low-class nomadic population visiting the district for short periods in the summer and with the conveyance and storage of manure. Everyone familiar with rural districts around London will sympathise with him in his troubles, more especially as he appears to have added to them, especially at Greenhithe, a growing smoke nuisance from cement burning. Apparently the fruit-picking cannot be carried out by the local population, partly because it is too small and partly because the wage which the inhabitants demand is too high to render the industry remunerative; hence this alien trouble. The main nuisance has occurred at Swanley Junction, but here Dr. Richmond has at last succeeded in procuring a sewer to

had been 97 and 129 in the two previous weeks, declined again to 116 in the week under notice, and were 17 below the number in the corresponding period of the five years 1902-06. The causes of 43, or 1·1 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Leeds, West Ham, Bradford, Newcastle-on-Tyne, Hull, and in 48 other of the 76 towns; there were six uncertified deaths in Liverpool, five in Birmingham, three in Salford and in Reading, and two each in Manchester, Bristol, Sheffield, South Shields, Gateshead, Preston, St. Helens, and Bootle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 12·6, 12·8, and 13·7 per 1000 in the three preceding weeks, was 13·6 per 1000 in the week ending Sept. 7th, and exceeded by 1·3 per 1000 the rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·5 in Perth and 10·6 in Leith to 14·2 in Dundee and 14·8 in Glasgow. The 471 deaths in these towns were slightly fewer than the number in the preceding week, and included 58 which were referred to the principal epidemic diseases, against 65 and 62 in the two preceding weeks. These 58 deaths were equal to an annual rate of 1·7 per 1000, which exceeded by 0·2 per 1000 the mean rate during the same period from the principal epidemic diseases in the 76 large English towns; they included 22 which were referred to whooping-cough, 22 to diarrhœa, 11 to "fever," and one each to measles, to scarlet fever, and to diphtheria. The fatal cases of whooping-cough, which had been 22 and 19 in the two preceding weeks, rose again to 22 last week, and included ten in Glasgow, five in Edinburgh, and five in Aberdeen. The deaths from diarrhœa, which had been 21 and 15 in the two preceding weeks, increased again last week to 22, of which 15 occurred in Glasgow, five in Aberdeen, and two in Dundee. The fatal cases of "fever," which had been seven and 19 in the two preceding weeks, declined again to 11 last week, and included 10 in Glasgow and one in Edinburgh; of these eight were attributed to cerebro-spinal meningitis in Glasgow, and one in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 48, 53, and 51 in the three preceding weeks, rose to 57 in the week under notice, and exceeded by seven the number in the corresponding period of last year. The causes of 21, or 4·4 per cent., of the deaths in these eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 1·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 15·7 and 18·6 per 1000 in the two preceding weeks, further rose to 20·7 per 1000 in the week ending Sept. 7th. During the first ten weeks of the current quarter the death-rate has averaged 18·9 per 1000, the rates during the same period being only 11·9 in London and 12·3 in Edinburgh. The 155 deaths of Dublin residents registered during the week under notice were 16 in excess of the number in the previous week, and included 12 which were referred to the principal epidemic diseases, against 14 and 17 in the two preceding weeks; they included five from diarrhœa, three from measles, two from whooping-cough, one from scarlet fever, and one from "fever," but not any from small-pox or from diphtheria. These 12 deaths were equal to an annual rate of 1·6 per 1000, the death-rate from the principal epidemic diseases during the same period being 1·5 in London and 1·1 in Edinburgh. The fatal cases of diarrhœa, which had been six, four, and eight in the three preceding weeks, declined again last week to five, while the deaths from measles decreased to three, having been two and seven in the two previous weeks. The 155 deaths from all causes in Dublin last week included 29 of children under one year of age and 50 of persons aged upwards of 60 years, these numbers being respectively five and 19 in excess of the corresponding figures for the previous week. Four inquest cases and three deaths from violence were registered, and 61, or 39·4 per cent., of the deaths occurred in public institutions. The causes of seven, or 4·5 per cent., of the deaths in Dublin last week were not certified; in London all the deaths were duly certified, while in Edinburgh the proportion of uncertified deaths was 5·8 per cent. The 105 deaths in Belfast included five which were referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: J. A. Keogh to the *President*, for three months' course at West London Hospital; E. Sutton to the *Kent*, on recommissioning; and O. W. Andrews to the *President*, additional, for International Congress of Hygiene and Demography at Berlin. Surgeons: S. S. H. Shannon to the *Arrogant*, on recommissioning; J. E. Johnston to the *Pembroke* for Royal Naval Barracks; F. E. Bolton to the *Kinsha*, R Kennedy to the *Glory*, and E. Cox to Chatham Hospital; A. H. S. Richardson to the *Amphitrite*, and to the *Kent*, on recommissioning; and R. Thompson to the *Cambridge*.

ROYAL ARMY MEDICAL CORPS.

Major Alfred L. Borradaile retires on retired pay (dated Sept. 7th, 1907). Lieutenant-Colonel W. L. Reade and Major A. O. Stone have been permitted to exchange appointments by the Army Council.

INDIAN MEDICAL SERVICE.

The following Lieutenant Colonels retire from the service:—Charles Lethbridge Swaine (dated July 23rd, 1907), Nityananda Chatterjie (dated June 18th, 1907), Alexander Vass Anderson (dated July 19th, 1907), and Herbert Mackinlay Morris (dated May 14th, 1907).

IMPERIAL YEOMANRY.

Scottish Horse: Surgeon-Lieutenant J. A. Taylor to be Surgeon-Captain (dated August 1st, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Forfarshire: Surgeon-Captain G. Halley to be Surgeon-Major (dated July 29th, 1907).

Rifle: 2nd Volunteer Battalion the Royal Warwickshire Regiment: Arthur James Arch (late Lieutenant, R.A.M.C.) to be Second Lieutenant (dated July 20th, 1907). 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Prosper James Liston to be Surgeon-Lieutenant (dated August 12th, 1907). 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry): Supernumerary Surgeon-Major E. Lee (Brigade-Surgeon Lieutenant-Colonel, Senior Medical Officer, Humber Volunteer Infantry Brigade), to be Surgeon Lieutenant-Colonel, remaining seconded (dated July 18th, 1903). 1st Volunteer Battalion the Duke of Cambridge's Own (Middlesex Regiment): Surgeon-Lieutenant H. W. Spaight resigns his commission (dated August 1st, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Eastern Command: Woolwich Companies: Lieutenant A. E. Jerman to be Captain (dated August 6th, 1907). London District: London Companies: Allan Chilcott Parsons to be Lieutenant (dated Sept. 1st, 1907). Argyll and Sutherland Bearer Company: Captain J. A. Boyd resigns his commission (dated August 12th, 1907). East Surrey Bearer Company: Captain (Surgeon-Major, Army Medical Reserve of Officers, Honorary Captain in the Army) E. W. St. V. Ryan resigns his commission (dated July 17th, 1907).

The Woolwich Companies, numbering 13 officers and 392 non-commissioned officers and men under the command of Lieutentant-Colonel C. H. Hartt, completed their 14 days' training at Netley on August 17th. They were encamped in a field in the rear of the hospital. On August 9th they were inspected by Surgeon-General R. H. Quill, Principal Medical Officer, Royal Victoria Hospital. Besides being engaged in field exercises 30 of the men were drafted each day into the wards of the hospital to learn the special duties connected with nursing.

DEATHS IN THE SERVICES.

Lieutenant-Colonel Herbert Jekyl Dyson, I.M.S., in Calcutta, on Sept. 3rd. He obtained his medical qualifications in 1882, entered the service as surgeon in April, 1885, and was promoted to be lieutenant-colonel in April, 1905. He served with the Burmese Expedition in 1885–88 and received the medal with two clasps. He also held the position of civil surgeon at Jessore.

of world-wide reputation.—Dr. William Thomson, formerly professor of ophthalmology in the Jefferson Medical College, Philadelphia.—Dr. William Howard, formerly professor of gynæcology and children's diseases in the University of Maryland, Baltimore.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in August the following candidates passed in the subjects indicated:—

Surgery.—H. W. B. Danaher (Section I.), London Hospital; C. L. Driscoll (Sections I. and II.), Charing Cross Hospital; and B. S. Matthews (Section I.), Royal Free Hospital.

Medicine.—T. T. Apsimon (Sections I. and II.), Liverpool; E. V. Connellan (Section II.), Bristol; M. F. Emrys-Jones (Section I.), Cambridge and Manchester; B. S. Matthews (Section I.), Royal Free Hospital; A. F. Reardon (Section II.), St. Thomas's Hospital; and E. E. Wilbe, St. Bartholomew's Hospital.

Forensic Medicine.—T. T. Apsimon, Liverpool; M. F. Emrys-Jones, Cambridge and Manchester; B. S. Matthews, Royal Free Hospital; H. W. Phillips, Manchester; M. Rathbone, Royal Free Hospital; E. E. Wilbe, St. Bartholomew's Hospital; and G. F. Wilson, London Hospital.

Midwifery.—J. A. Byrne, Manchester; C. L. Driscoll, Charing Cross Hospital; G. W. Hassall, Birmingham; and E. E. Wilbe, St. Bartholomew's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—C. L. Driscoll and E. E. Wilbe.

FOREIGN UNIVERSITY INTELLIGENCE.—*Alabama (Medical College)*: Dr. William Salant of New York has been appointed Assistant Professor of Physiological Chemistry and Pharmacology.—*Bologna*: Dr. Carlo Vignolo-Lutati has been recognised as *privat-docent* of Dermatology and Dr. Ugo Biffi Gentili as *privat-docent* of Experimental Hygiene.—*Budapest*: Dr. Paul Hari has been recognised as *privat-docent* of Pathological Chemistry.—*Chicago (Rush Medical College)*: Dr. William H. Wilder has been appointed Professor of Ophthalmology in succession to Dr. F. C. Hotz who retires.—*Greifswald*: Dr. Rudolf Haecker has been recognised as *privat-docent* of Surgery.—*New Haven (College of Physicians and Surgeons)*: Dr. F. Huber has been appointed Professor of Medicine and Dr. Peterson Professor of Psychiatry.—*New York (College of Physicians and Surgeons)*: Dr. Andrew McCosh has been appointed Professor of Surgery.—*Ohio (Medical College)*: Dr. E. Otis Smith has been appointed Professor of Genito-Urinary Diseases in succession to Dr. Evans who retires.—*Philadelphia (Medico-Surgical College)*: Dr. Theodore H. Weisenburg has been appointed Professor of Neurology and Psychiatry in succession to the late Dr. W. Pickett.—*Toronto*: Dr. J. P. McMurrick of the Ann Arbor University has been appointed Professor of Anatomy in succession to Dr. Primrose who retires.—*Tübingen*: Dr. Ottfried Müller has been appointed Extraordinary Professor of Medicine in succession to the late Dr. von Jürgensen.—*Vienna*: Dr. C. F. Grosz been recognised as *privat docent* of Dermatology.—*Würzburg*: Dr. Alexander Schmincke has been recognised as *privat-docent* of General Pathology and Pathological Anatomy.

KINGSWOOD (NEAR BRISTOL) DRAINAGE SCHEME.—A Local Government Board inquiry was held at Kingswood on Sept. 4th into the application of the local council to borrow £10,000 for the purpose of the Warmley section of the Kingswood drainage scheme.

RUSSIAN MEDICAL PRACTITIONERS AND THE POLICE.—A notice has been published at Tchernigoff by the governor requiring medical men to notify to the police any cases of wounds from firearms or other weapons that may come under their care, and likewise to furnish the police with the names and addresses of such people as may be accommodating these patients. The penalty for disobedience to these requirements is a fine of £50 or three months' imprisonment.

MANSLAUGHTER IN AN ASYLUM.—At an inquest held on Sept. 6th respecting the death of an inmate, aged 70 years, of the Wonford Asylum, near Exeter, a verdict of "manslaughter" was returned against another patient of the institution. The patients were dining and whilst the attendant's back was turned the prisoner, it is alleged, inflicted a wound on the cheek of the man with a dinner knife, causing injuries which subsequently proved fatal. It is stated that the two men had dined together for years and always appeared to be on friendly terms.

MEDICAL MAGISTRATE.—Mr. Jerome Eugene O'Sullivan, L.R.C.P., L.R.C.S. Edin., has been placed on the commission of the peace for the city of Liverpool.

TOTNES WORKHOUSE INFIRMARY.—At a meeting of the Totnes (Devon) board of guardians held on August 30th a tender for the erection of the workhouse infirmary for £7164 was accepted.

DISEASED CATTLE.—The Local Government Board has issued a circular to local authorities stating that it has had under consideration various representations with respect to the sale for human food of diseased cattle and especially of cows suffering from tuberculosis or other wasting disease. The Board understands that it is the practice of some dealers, though aware of the diseased condition of animals coming into their hands, so to dispose of them or of their carcasses, that there is risk that they will be used as food for the poorer classes in London and other large towns. The Board has reason to believe that the practice in question obtains to a considerable extent; and accordingly it is desirous of drawing the attention of local authorities to the matter, in order that they may as far as possible exercise supervision over the cattle in their districts with a view to anticipating, and so averting, possible or intended infringement of the law. With this object the local authority should instruct such of its officers as are engaged in administering the provisions of the Dairies, Cowsheds, and Milkshops Orders, to observe particularly the condition of the cows which come under its notice, and, where any animal is clearly diseased and presumably unfit for food, to take such steps as are practicable to insure that, in the event of the animal being slaughtered, the carcass is disposed of properly. The Board also suggests that the sanitary or other suitable officers of the local authority should be instructed to watch closely the cattle-markets, slaughter-houses, and knackers' yards in the district, with the view of satisfying themselves that no animal, the condition of which appears to render it unfit for human consumption, is disposed of in such a manner that it is likely to be used for this purpose.

BOOKS, ETC., RECEIVED.

APPLETON, SIDNEY, 25, Bedford-street, Covent Garden, London, W.C.

Modern Clinical Medicine. Diseases of the Digestive System. Edited by Frank Billings, M.D., Professor of Medicine, University of Chicago and Professor of Medicine and Dean of Faculty, Rush Medical College. An Authorized Translation from "Die Deutsche Klinik," under the General Editorial Supervision of Julius L. Salinger, M.D. Price 25s. net.

GRIFFIN, CHARLES, AND COMPANY, LIMITED, Exeter street, Strand, London, W.C.

Medical Ethics: A Guide to Professional Conduct. By Robert Saundby, M.D. Edin., Hon. LL.D., McGill; Hon. M.Sc., Birm.; Fellow of the Roy. Coll. of Phys. of Lond.; Member of the General Medical Council; Vice-Pres., late Pres., of the Council of the Brit. Med. Assoc.; Emeritus Sen. Pres., of the Roy. Med. Soc., the opposing claimants is in a position to disdain the aid afforded it by the other in unravelling the complex clinical phenomena grouped under that vague, ill-defined term rheumatoid arthritis. For while, on the one hand, it cannot be gainsaid that many of the clinical features strongly savour of an infective process as, for example, the acute mode of onset of some cases, the lymphatic and occasional splenic enlargement, still, it must not be forgotten that even in cases presenting the above features there may be in addition widespread muscular atrophy, increased deep reflexes, symmetrical involvement of joints, and trophic changes.

Now such features as these latter strongly point to some implication of the nerve centres, and in order to make the infective theory fit all the facts of the case we have to explain them by assuming them to be the result of changes in the central nervous system consequent upon absorption of toxins. We thus see that in many cases it is impossible to dissociate the two theories, for, as a matter of fact, the manifold clinical phenomena of rheumatoid arthritis are best explained by a blend of the two views; and some years ago I endeavoured to explain this complex disorder on the basis of a chronic spinal toxæmia. Another advantage to be obtained by blending and not opposing the two views is that it leads us to take a more comprehensive view of the disease as a whole, for otherwise there is a distinct danger of our falling into the pitfall, stumbled into by so many, of regarding rheumatoid arthritis as a disease of joints and joints only, whereas, I take it, it is a disease of joints plus certain collateral phenomena, as, for example, muscular atrophy, sensory, vaso-motor, and trophic changes—in other words, the very phenomena which give to rheumatoid arthritis its characteristic clinical facies as opposed to all other joint affections.

When brought in contact with a series of rheumatoid patients we note that while they all present joint swellings of the same character they each may show important differences when looked at as a whole—i.e., muscular atrophy, intense and widespread, may obtain in the one; in another muscular atrophy may be slight but it may be characterised by vaso-motor phenomena indistinguishable clinically from Raynaud's disease. In yet another the predominant accessory features may be sensory, as evidenced by severe neuralgic pains and in some long-standing cases definite anæsthesia, and there may be areas of glossy skin, pigmentation, and in very rare cases perforating ulcers. The importance of a thorough all-round examination in all cases of rheumatoid arthritis is obvious, for it is just to these collateral phenomena that we look for a clue as to the nature of the joint trouble. Furthermore, I believe that these accessory features will eventually aid us considerably in establishing a sound clinical classification of the various forms. We are all aware how urgent is the need for an adequate classification of the joint diseases grouped under the term rheumatoid arthritis, and here again we might take a lesson from the way in which the arthropathies are classified. The neurologists do not content themselves with a classification based upon the mere anatomical distribution of the lesions, monarticular, polyarticular, and so forth. Nay, on the other hand, they classify them as tabetic, syringomyelic, &c. In other words, they look at their cases as a whole, and I cannot help thinking that if we approached the study of our rheumatoid patients in the same methodical manner, we should be able to evolve some classification more scientific than one based on the mere anatomical distribution of the lesions.

In support of my contention that the neural theory is still worthy of attention I would draw attention to an article[1] by Dr. F. W. Mott and Mr. A. F. Tredgold. It is entitled "Some Observations on Primary Degeneration of the Motor Tract." In it are discussed, both from a clinical and a pathological point of view, two cases of amyotrophic lateral sclerosis, one of progressive muscular atrophy, and a case of chronic rheumatoid arthritis with muscular atrophy. The microscopical examination of the cord of the last-named revealed "in the spinal cord chronic atrophy with excessive pigmentation of anterior horn cells in cervical and lumbar enlargements, all groups affected (especially the mesial anterior). Decrease in fibrillary network. General slight interstitial overgrowth throughout the cord, with arterio-capillary fibrosis, but no tract degeneration, slight chronic changes in cells of posterior ganglia, atrophy of peripheral nerve fibres, atrophy and fatty degeneration of muscles." It is only fair to add that the authors, after commenting on the remarkable similarity of the microscopical appearances in the cord sections of all four cases, felt themselves unable to say "whether the change in the anterior horn cells is primary or secondary to the joint change, or to give any satisfactory explanation of this difference, we simply record the fact."

In conclusion, I should like to add my testimony to the very great value of counter-irritation of the spine in rheumatoid arthritis. I have had the opportunity of seeing one of Dr. W. J. Midelton's cases both before and after treatment by Dr. Latham's method had been adopted and I can truthfully state that the results more than justified his strenuous advocacy of the method. Apologising for the length of my communication,

I am, Sirs, yours faithfully,
Bath, Sept. 11th, 1907. R. LLEWELYN JONES, M.B. Lond.

[1] Some Observations on Primary Degeneration of the Motor Tract. Brain, Part IV., 1902.

BODILY POSTURE AND CARDIAC PHYSICAL SIGNS.

To the Editors of THE LANCET.

SIRS,—The paper upon the above subject which appears in THE LANCET of August 10th, p. 353, from the pen of Dr. William Gordon raises many interesting points and rightly accentuates the importance of examining the heart both in the horizontal and the vertical postures of the body. With most of Dr. Gordon's conclusions I fully agree, but would differ with him upon several small points. The effect of posture upon cardiac dulness is usually very marked, this dulness becoming narrower and higher in the recumbent than in the vertical postures. This change seems to be due to the fact that in the vertical posture the heart gravitates downwards and forwards, while in the horizontal posture it tends to gravitate away from the sternum. Dr. Gordon would urge that when this change is greater than usual and the patient shows little or no cardiac dulness when horizontal, it is a sign of some value of cancer, but although this is present in cancer it is also so in any case of rapid emaciation, more especially when this occurs in young people. This point has been worked out by several German observers.

It is quite beyond cavil that most systolic cardiac murmurs, especially those due to "functional disturbance," are more distinct or even only present when the patient is recumbent. I have amply confirmed Dr. Gordon's observation that the antero posterior diameter of the chest is usually less in the recumbent than in the vertical postures but must demur when Dr. Gordon explains such increase in murmurs in the recumbent posture by saying that then "the stethoscope is relatively much nearer the pulmonary valves, relatively a good deal nearer the aortic valves, and relatively somewhat nearer the tricuspid and mitral valves." Dr. S. Cummings and I showed last year[1] that in the horizontal posture the heart tends to gravitate away from the sternum and Roentgen ray photographs taken from the side show then an increased space between the heart and the anterior chest wall. Hence one can argue that during auscultation of the heart with the patient recumbent the cardiac orifices are further away from the stethoscope than they are when such examination is conducted with the patient vertical. Moreover, it is evident to any observer that the normal heart sounds tend to be more audible when the individual examined is vertical than when he is recumbent; in fact, occasionally in thick-chested emphysematous people the heart may *only* be heard when the chest is vertical or, better still, leaning forward.

While quite admitting that the normal heart sounds are qualitatively changed by posture, the first being sharper and the second duller in the erect posture than in the horizontal, it seems to me that by far the most evident change in the sounds is that they are both more audible in the vertical than in the recumbent position. And this is only what one would expect if the contention is correct that in the erect posture the heart is nearer to the stethoscope. Why systolic murmurs should be more evident in the horizontal than in the upright posture is a different question and I agree with part of Dr. Gordon's explanation of the phenomenon when he argues that "it is due to the action of

Neild, F. M., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed a Resident House Surgeon at St. Thomas's Hospital.

Nightingale, H. J., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed a Resident House Surgeon at St. Thomas's Hospital.

Palmer, F. W. Morton, M.B., B.C. Cantab., has been appointed Ophthalmic Surgeon to the Teignmouth Hospital.

Patey, W., M.R.C.S., L.R.C.P., has received a Resident Appointment in the Ear Department at St. Thomas's Hospital.

Phippen, Harry G., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Assistant Medical Officer at the Western Hospital, Fulham, London, S.W.

Sparrow, E. C., M.R.C.S., L.R.C.P., has received a Resident Appointment in the Skin Department at St. Thomas's Hospital.

Todd, R. E., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed a House Surgeon *to* Out-Patients at St. Thomas's Hospital.

Unwin, H. R., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed a Resident House Surgeon at St. Thomas's Hospital.

Vendon, W. H. G., M.R.C.S., L.R.C.P., has received a Resident Appointment in the Ear Department at St. Thomas's Hospital.

Whitehouse, H. B., M.B., B.S. Lond., M.R.C.S., L.R.C.P., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

Windsor, J. F., M.R.C.S., L.R.C.P., has received a Resident Appointment in the Skin Department at St. Thomas's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead Borough Hospital.—Junior Resident House Surgeon. Salary £80 and fees.

Birmingham General Hospital.—Two Receiving-room Officers. Salary £150 per annum.

Birmingham, Queen's Hospital.—House Surgeon *for six months*. Salary at rate of £50 per annum, with board, lodging, and washing.

Brentford Union Workhouse and Schools, Isleworth, W.—Second Assistant Medical Officer, unmarried. Salary £125 per annum, with lunch and tea.

Bridge of Weir.—Assistant Resident Medical Officer (Lady) for Consumption Sanatoria.

Brighton, Royal Alexandra Hospital for Sick Children, Dyke-road.—House Surgeon. Salary at rate of £80 a year, with board, lodging, and washing.

Bristol Royal Infirmary.—Resident Casualty Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

Central London Ophthalmic Hospital, Gray's Inn-road, W.C.—House Surgeon. Salary at rate of £50 per annum, with board and residence.

Chelsea Infirmary, Cale-street, S.W.—Second Assistant Medical Officer. Salary £90, rising to £100 a year, with board, apartments, washing, coal, gas, &c.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary 100 guineas per annum. Also Two House Physicians for six months. Salary at rate of £50 per annum, with board, washing, and residence. Also Clinical Assistant. Also Locum Tenens House Physician.

Dorchester, Dorset County Hospital.—House Surgeon, unmarried. Salary £100, with board and lodging.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E.—Clinical Assistants.

Farringdon General Dispensary, 17, Bartlett's Buildings, Holborn Circus, E.C.—Resident Medical Officer. Salary £120 per annum, with apartments, coal, gas, and attendance. Also Honorary Dental Surgeon.

Glasgow University.—Examinerships in Natural *Philosophy* (salary £70), Chemistry (salary £50), Botany (salary £50), Anatomy (salary £80), Medical Jurisprudence (salary £50), Medicine (salary £80), Surgery (salary £80), and Midwifery (salary £50); *with hotel and* travelling expenses in each case. Also Junior Assistant in Physiological Department.

Gravesend Hospital.—House Surgeon. Salary £100 per annum, with board and residence.

Great Northern Central Hospital, Holloway.—Senior House Surgeon, Senior House Physician, Two Junior House Surgeons, and One Junior House Physician. Salary of Senior Officers at rate of £60 per annum *and of* Junior Officers at rate of £30 per annum, with board, lodging, and washing.

Jersey Dispensary.—Resident Medical Officer. Salary £120, with furnished quarters and attendance.

King's Lynn, West Norfolk and Lynn Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

Liverpool Infirmary for Children.—Assistant House Surgeon for six months. Salary £30, with board and lodging.

London Lock Hospital and Rescue Home, Harrow-road, W.—Honorary Dental Surgeon.

London Lock Hospital, Dean-street, W.—Anæsthetist.

London Temperance Hospital, Hampstead road, N.W.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing.

Manchester Chorlton Union Workhouse Hospitals, Withington.—Senior Resident Medical Officer. Salary £100 per annum, with rations, apartments, and attendance.

Manchester, Chorlton-upon-Medlock Dispensary.—Honorary Medical Officer.

Manchester Northern Hospital for Women and Children, *Park-place*, Cheetham Hill-road.—House Surgeon. Salary £80 per annum, with apartments and board.

Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead.—Junior Resident Medical Officer. Salary £50 per annum, with board, lodging, &c.

Newcastle-upon-Tyne, City Hospital for Infectious Diseases.—Resident Medical Assistant. Salary £104 per annum, with board, lodging, &c.

Newcastle-upon-Tyne, University of Durham College of Medicine.—Demonstrator of Physiology. Salary £200 per annum.

Norwich City Asylum, Hellesdon-next-Norwich.—Resident Medical Superintendent. Salary £400 per annum, *rising to £600*, with furnished residence, fuel, light, rates, washing, &c.

Plymouth, South Devon and East Cornwall Hospital.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, and washing.

Royal Dental Hospital, Leicester-square.—Morning House Anæsthetist. Honorarium £50 per annum.

Royal Hospital for Diseases of the Chest, City road, E.C.—House Physician for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

Royal London Ophthalmic Hospital, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 a year, with board and residence.

Royal National Orthopædic Hospital.—Honorary Dental Surgeon. Also Honorary Assistant Anæsthetist.

Salford Union Infirmary, Hope, Pendleton.—Resident Medical Officer. Salary £130 per annum, with apartments and attendance.

Samaritan Free Hospital for Women, Marylebone road, N.W.—Clinical Assistants.

Sheffield Royal Hospital.—Assistant House Physician, unmarried. Salary £50 per annum, *with board, lodging, and washing.*

Sheffield Union Hospital.—Resident Assistant Medical Officer. Salary £80 per annum, with apartments, rations, and allowances.

Stafford, Staffordshire General Infirmary.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

Throat Hospital, Golden-square, W.—Senior Clinical Assistants.

Tunbridge Wells, General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance.

Warrington, Lancashire County Asylum, Winwick.—Locum Tenens Medical Officer, unmarried. Salary 4 guineas per week, with apartments, board, attendance, and washing.

Births, Marriages, and Deaths.

BIRTHS.

Akers.—On Sept. 7th, at Hove, the wife of W. Dutton Akers, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., *of a son.*

Corfield.—On Sept. 4th, at Upper Tooting, the wife of Edward Carruthers Corfield, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

Hartigan.—On Sept. 4th, *at Gloucester-terrace, Hyde Park*, W., the wife of Dr. Thomas Hartigan, of a son.

Lett.—On Sept. 4th, at 48, Queen Anne-street, W., the wife of Hugh Lett, M.B., F.R.C.S., *of a daughter.*

Macevoy.—On Sept. 11th, 1907, at 41, Buckley-road, Brondesbury, N.W., the wife of H. J. Macevoy, M.D., B Sc. *Lond., of a son.*

Naish.—On August 29th, at Upton-on-Severn, the wife of Dr. W. V. Naish, of a daughter.

Nunneley.—On Sept. 2nd, at Elstree, the wife of Frederick Pitcairn Nunneley, M.D., of a daughter.

Routch.—On Sept. 3rd, at Tunbridge Wells, the wife of Dr. Frederick *Routch, of a daughter.*

Walker.—At 19, Atholl-crescent, Edinburgh, on Sept. *9th*, the wife of Dr. Sydney R. Walker, of a son.

MARRIAGES.

Daniel—Bapty.—On Sept. 5th, at Epsom Parish Church, Alfred Wilson Daniel, M.D., son of the late Dr. W. C. Daniel, of The Silver Birches, Epsom, to Lena Gertrude Lucie Lee Bapty, daughter of Samuel Lee Bapty, of Birmingham.

Gaitskell—Wild.—On Sept. 5th, at St. Margaret's, Westminster, Charles Edward Gaitskell, M.R.C.S., L.R.C.P., to Ethel Linda, daughter of Robert Wild.

Gardner—Warren.—On Sept. 10th, at the Parish Church, *Caterham*, by the Rev. F. T. Gardner, M.A. (brother of the bridegroom), Rector of Nunney, near Frome, William Gardner, of Woodcote Manor, Chaddesley Corbett, son of the late Thomas Gardner, of Goldhanger, Essex, and Mary Letitia, daughter of the late James Warren, of Capel House, Waltham Cross, and granddaughter of the *late John* Shepard, of Sylva House, Caterham.

Smith—Hampson.—On Sept. 4th, at St. James's Church, Southport, Dr. Herbert Austen Smith to Constance *Hampson, daughter of* Mr. and Mrs. Hampson.

DEATHS.

Clark.—On Sept. 4th, at Dorking, *Charles* MacKinnon Clark, M.D., L.R.C.P., M.R.C.S., aged 42 years.

Dyson.—On Sept. 3rd, at the Presidency Hospital, *Calcutta*, Lieutenant-Colonel H. J. Dyson, F.R.C.S., I.M.S., aged 47 years.

Hamilton.—On August 4th, at Melbourne, Victoria, Caroline Ring, beloved wife of Henry Talbot Hamilton, M.B., B.S., and youngest *daughter of* the late Francis Workman, M.R.C.S., formerly of Reading.

Hirst.—On August 31st, at Westfield-terrace, Chapel-Allerton, Leeds, Walter C. Hirst, M.B. Lond., *aged* 29.

Holmes.—On Sept. 8th, at Sussex-place, *Hyde Park*, W., Timothy Holmes, F.R.C.S., aged 82 years.

Logan.—At Ravenswood, South Drive, Harrogate, on Sept. 4th, Thomas Logan, M.D., late of *Wibsey*, Bradford. Friends will please accept this intimation.

Westcott.—On Sept. 6th, at Whitmead, near Farnham, Edmund William Martyn Westcott, M.R.C.S. and L.R.C.P., late Surgeon to River Nile Steamship *Amasis.*

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

the opposing claimants is in a position to disdain the aid afforded it by the other in unravelling the complex clinical phenomena grouped under that vague, ill-defined term rheumatoid arthritis. For while, on the one hand, it cannot be gainsaid that many of the clinical features strongly savour of an infective process as, for example, the acute mode of onset of some cases, the lymphatic and occasional splenic enlargement, still, it must not be forgotten that even in cases presenting the above features there may be in addition widespread muscular atrophy, increased deep reflexes, symmetrical involvement of joints, and trophic changes.

Now such features as these latter strongly point to some implication of the nerve centres, and in order to make the infective theory fit all the facts of the case we have to explain them by assuming them to be the result of changes in the central nervous system consequent upon absorption of toxins. We thus see that in many cases it is impossible to dissociate the two theories, for, as a matter of fact, the manifold clinical phenomena of rheumatoid arthritis are best explained by a blend of the two views; and some years ago I endeavoured to explain this complex disorder on the basis of a chronic spinal toxæmia. Another advantage to be obtained by blending and not opposing the two views is that it leads us to take a more comprehensive view of the disease as a whole, for otherwise there is a distinct danger of our falling into the pitfall, stumbled into by so many, of regarding rheumatoid arthritis as a disease of joints and joints only, whereas, I take it, it is a disease of joints plus certain collateral phenomena, as, for example, muscular atrophy, sensory, vaso-motor, and trophic changes—in other words, the very phenomena which give to rheumatoid arthritis its characteristic clinical facies as opposed to all other joint affections.

When brought in contact with a series of rheumatoid patients we note that while they all present *joint swellings* of the same character they each may show important differences when looked at as a whole—i.e., *muscular atrophy, intense and widespread, may obtain in the one*: in another muscular atrophy may be *slight but it may be characterised by vaso-motor phenomena indistinguishable clinically from Raynaud's disease.* In yet another the predominant accessory features may be sensory, as evidenced by severe neuralgic pains and in some long-standing cases definite anæsthesia, and there may be areas of glossy skin, pigmentation, and in very rare cases perforating ulcers. The importance of a thorough all-round examination in all cases of rheumatoid arthritis is obvious, for it is just to these collateral phenomena that we look for a clue as to the nature of the joint trouble. Furthermore, I believe that these accessory features will eventually aid us considerably in establishing a sound clinical classification of the various forms. We are all aware how urgent is the need for an adequate classification of the joint diseases grouped under the term rheumatoid arthritis, and here again we might take a lesson from the way in which the arthropathies are classified. The neurologists do not content themselves with a classification based upon the mere anatomical distribution of the lesions, monarticular, polyarticular, and so forth. Nay, on the other hand, they classify them as tabetic, syringomyelic, &c. In other words, they look at their cases as a whole, and I cannot help thinking that if we approached the study of our rheumatoid patients in the same methodical manner, we should be able to evolve some classification more scientific than one based on the mere anatomical distribution of the lesions.

In support of my contention that the neural theory is still worthy of attention I would draw attention to an article[1] by Dr. F. W. Mott and Mr. A. F. Tredgold. It is entitled "Some Observations on Primary Degeneration of the Motor Tract." In it are discussed, both from a clinical and a pathological point of view, two cases of amyotrophic lateral sclerosis, one of progressive muscular atrophy, and a case of chronic rheumatoid arthritis with muscular atrophy. The microscopical examination of the cord of the last-named revealed "in the spinal cord chronic atrophy with excessive pigmentation of anterior horn cells in cervical and lumbar enlargements, all groups affected (especially the mesial anterior). Decrease in fibrillary network. General slight interstitial overgrowth throughout the cord, with arterio-capillary fibrosis, but no tract degeneration, slight chronic changes in cells of posterior ganglia, atrophy of peripheral nerve fibres, atrophy and fatty degeneration of muscles." It is only fair to add that the authors, after commenting on the remarkable similarity of the microscopical appearances in the cord sections of all four cases, felt themselves unable to say "whether the change in the anterior horn cells is primary or secondary to the joint change, or to give any satisfactory explanation of this difference, we simply record the fact."

In conclusion, I should like to add my testimony to the very great value of counter-irritation of the spine in rheumatoid arthritis. I have had the opportunity of seeing one of Dr. W. J. Midelton's cases both before and after treatment by Dr. Latham's method had been adopted and I can truthfully state that the results more than justified his strenuous advocacy of the method. Apologising for the length of my communication,

I am, Sirs, yours faithfully,
Bath, Sept. 11th, 1907. R. Llewelyn Jones, M.B. Lond.

BODILY POSTURE AND CARDIAC PHYSICAL SIGNS.

To the Editors of The Lancet.

Sirs,—The paper upon the above subject which appears in The Lancet of August 10th, p. 353, from the pen of Dr. William Gordon raises many interesting points and rightly accentuates the importance of examining the heart both in the horizontal and the vertical postures of the body. With most of Dr. Gordon's conclusions I fully agree, but would differ with him upon several small points. The effect of posture upon cardiac dulness is usually very marked, this dulness becoming narrower and higher in the recumbent than in the vertical postures. This change seems to be due to the fact that in the vertical posture the heart gravitates downwards and forwards, while in the horizontal posture it tends to gravitate away from the sternum. Dr. Gordon would urge that when this change is greater than usual and the patient shows little or no cardiac dulness when horizontal, it is a sign of some [illegible] of cancer, but although this is present in cancer it is also so in any state of rapid emaciation, more especially when this occurs in young people. This point has been worked out by several German observers.

It is quite beyond cavil that most systolic cardiac murmurs, especially those due to "functional disturbance," are more distinct or even only present when the patient is recumbent. I have amply confirmed Dr. Gordon's observation that the antero posterior diameter of the chest is usually less in the recumbent than in the vertical postures but must demur when Dr. Gordon explains such increase in murmurs in the recumbent posture by saying that then "the stethoscope is relatively much nearer the pulmonary valves, relatively a good deal nearer the aortic valves, and relatively somewhat nearer the tricuspid and mitral valves." Dr. S. Cummings and I showed last year[1] that in the horizontal posture the heart tends to gravitate away from the sternum and Roentgen ray photographs taken from the side show then an increased space between the heart and the anterior chest wall. Hence one can argue that during auscultation of the heart with the patient recumbent the cardiac orifices are further away from the stethoscope than they are when such examination is conducted with the patient vertical. Moreover, it is evident to any observer that the normal heart sounds tend to be more audible when the individual examined is vertical than when he is recumbent; in fact, occasionally in thick-chested emphysematous people the heart may *only* be heard when the chest is vertical or, better still, leaning forward.

While quite admitting that the normal heart sounds are qualitatively changed by posture, the first being sharper and the second duller in the erect posture than in the horizontal, it seems to me that by far the most evident change in the sounds is that they are both more audible in the vertical than in the recumbent position. And this is only what one would expect if the contention is correct that in the erect posture the heart is nearer to the stethoscope. Why systolic murmurs should be more evident in the horizontal than in the upright posture is a different question and I agree with part of Dr. Gordon's explanation of the phenomenon when he argues that "it is due to the action of

---

[1] Brit. Med. Jour., vol. ii., 1906, p. 1023.

Apply a thin coating to the broken surfaces of the vessel, which surfaces must be scrupulously clean, press them together, and, if possible, keep under pressure for 12 hours. 2. Another good cement for glass is the following: Solution of Russian isinglass. The solution should be of a thin, treacly consistence. Then add a few drops of a 5 per cent. solution of potassium bichromate. Use in the same way as the casein cement.—ED. L.

SOME QUERIES.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged by your inserting the following three inquiries in your columns:—

1. Can any of your readers give any information as regards the "Coppins' Green Sanatorium" near Clacton-on-Sea?

2. Have any of your readers bought a motor-car through the medium of the "Automobile Contract Co.," Conduit-street, W., and if so, what was their experience of their system of deferred payments?

3. What is the experience of any medical owner of the 8 h p. Rover two seater, 1907 model, as regards reliability, non-stopping, &c?

I am, Sirs, yours faithfully,

Sept. 8th, 1907. CYMRU.

THE "MARSHALL" SUSPENDER.

THE form of suspender depicted in the illustration is distinctly a useful one for the athlete or the sufferer from varicocele. The bag does not cut, chafe, or press upon the under side of the scrotum, the whole of the genitals being slung in it in a comfortable manner. In many surgical conditions and for those who go in for hunting or polo playing, for fencing or cycling, the suspender will be found very useful. The manufacturers of the suspender are Messrs. Croydon and Co, Limited, 55, Wigmore street, Cavendish-square, London, W.

AGE LIMIT.

To the Editors of THE LANCET.

SIRS,—I wish to draw general attention to the increasing fashion of public bodies of various sorts advertising appointments and including a statement that no person over 40 years of age need apply. I think many of your readers will agree with me that this limitation is quite unreasonable and contrary to public policy. Is there to be no refuge but the workhouse for men, probably with wives and families dependent on them, who after obtaining a ripe experience in some special branch of knowledge lose an appointment after the age of 40 years has been reached from circumstances over which they have no control and without any discredit to their honour. Age limit is an intelligible restriction in any case where superannuation pay would be forthcoming in due course, but not otherwise.

Would the councillors admit that they themselves are not doing, or capable of doing, useful work in an up-to-date manner, simply because they are over 40? I think not. Indeed, there are some "youngsters" of 65 years and upwards on my council who think that all the good work done here is due solely to their efforts.

I am, Sirs, yours faithfully,

Sept. 10th, 1907. NEC SENEX, NEC JUVENIS.

LOATHSOME BED STUFFING.

To the Editors of THE LANCET.

SIRS,—May I draw your attention to the urgent necessity that exists for the establishment of some system of inspection of the places where bedding is made or re-made and cleansed? That such work is sometimes carried out at present under the most insanitary and odious conditions is an undoubted fact, one, indeed, of which I have an ocular demonstration almost daily. My windows overlook the little back-yard of an upholsterer's shop in a respectable street in a fashionable quarter of London and there I see bedding "cleaned" in the following manner. The hair, flock, or wool contents of the beds or mattresses are emptied out either on an old door, an inadequate and dirty piece of canvas, or on the bare ground and beaten with rods by a lad or two, the stuff naturally flying hither and thither during the operation. The yard is unpaved, generally wet, always dirty; it is the playground of a family of children of unclean and disgusting habits, and in it are situated the water-closet, which is, I have reason to think, seldom, if ever, cleaned out, and the dust-bin. When the "cleaning" is finished the stray bedding stuff is swept up from the muddy yard and *from out of the closet*—this is the truth—and carried in ready to be packed into its new tick and returned to its blissfully ignorant owner.

The shop itself is quite tidy and clean, its tenant has every appearance of a respectable trustworthy tradesman, and no one who has not had the opportunity of getting a glimpse behind the scenes would suspect the real state of things. I fear that the case I am describing is not unique and the very idea that it is not so is disquieting.

I am, Sirs, yours faithfully,

Sept. 9th, 1907. R. B. K.

SANATORIUM TREATMENT OF TUBERCULOSIS.

EASTBY Sanatorium for the treatment of tuberculous patients chargeable to the board of guardians of Bradford in Yorkshire was opened in November, 1903, and a summary of the results obtained from that date up to June 30th, 1907, has been prepared by Dr. B. Holroyd Slater, the medical superintendent. The statistics show that 228 patients were admitted, two died, and 193 were discharged. For estimating the results of treatment the patients were divided into three classes—namely, Class A, in which the total extent of disease was not greater than two-thirds of one lobe of one lung; Class B, in which an area not greater than one and a half lobes was involved; and Class C, in which a greater area was involved. Of the patients admitted, 92 (i.e., 40·7 per cent.) belonged to Class A and 87 (i.e., 38·5 per cent.) to Class B; 50 of the former and four of the latter were discharged "provisionally cured." Of the 193 discharges, 151 occurred from six months to over three years ago, and of these patients 51 were last June in good health and full work.

THE REMOVAL OF POWDER STAINS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers offer a suggestion in the following case? An officer, as a result of a gunpowder explosion, has the whole of one side of his face marked by powder which is just beneath the skin, giving a freckled appearance. Are there any means of removing these particles or lessening the disfiguring appearance?

I am, Sirs, yours faithfully,

August 16th, 1907. A. F. H.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

be found of improvement. Of course, it would be necessary to administer the anæsthetic with the utmost care, bearing in mind the nature of the disease. Abdominal section has frequently been credited with temporary arrest of tuberculosis of that cavity. May not ether be the chief factor in the temporary arrest? I am, Sirs, yours faithfully,

Sept. 5th, 1907. ROBT. HUGH HODGSON.

THE SEASONS AND MENTAL DISORDERS.

To the Editors of THE LANCET.

SIRS,—The incidence of mental disorders does not correspond in point of time with recorded admissions into asylums, especially private asylums. It is true that the summer months, as indicated by Dr. J. Adam, bring special anxieties and maximum work, for suicides are most common in July and least common in November; but the inception of these disorders must be referred to the spring months, as I have shown in the Morison lectures of this year. It is undoubtedly in the study of the prodromal period and the onset of insanity that modern methods of treatment must find their bases and most hopeful development.

I am, Sirs, yours faithfully,

Perth, Sept. 7th, 1907. A. R. URQUHART.

TUBERCULOSIS IN SPAIN.

To the Editors of THE LANCET.

SIRS,—I am informed that after a fatal case of bacillary phthisis it is the *national custom in Spain to disinfect* and redecorate the room in which the fatal case occurred. Can you, or any reader of THE LANCET, inform me if this is a fact? I am, Sirs, yours faithfully,

Cornwall Sept 2nd, 1907. C. E. ABBOTT, M.R.C.S. Eng.

⁎⁎ *It* is a fact that tuberculosis is regarded in Spain as very infectious. It is difficult to let a house or rooms in which a patient has died from this disease. Moreover, the furniture is generally destroyed after the death.—ED. L.

THE GUILD OF ST. LUKE.

To the Editors of THE LANCET.

SIRS,—May I draw attention to the advertisement appearing in the present issue of THE LANCET respecting the annual festival service of the Guild of St. Luke to be held at St. Paul's Cathedral on Oct. 22nd and request that those who desire to attend will communicate with me as soon as possible; as we are expecting a large attendance from the City companies and others we are anxious to allot space as soon as possible. I am, Sirs, yours faithfully,

CLAUDE ST AUBYN-FARRER, Registrar.

7, Westbourne Park-road, London, W.,
Sept. 9th, 1907.

TEA SHOPS AND DUST.

To the Editors of THE LANCET.

SIRS,—May I draw your attention to the practice that seems to me insanitary and otherwise objectionable of sweeping the floors of tea shops while customers are eating and drinking. I admit it is not done during the busiest time, but I have just been suffering from it in one such shop at 2.40 to-day. A word of condemnation in your columns would go far to suppress this nuisance.

I am, Sirs, yours faithfully,

August 22nd, 1907. ACE.

THE ROYAL SOCIETY OF MEDICINE.

To the Editors of THE LANCET.

SIRS,—The usual annual issue by the editors of the Medical Directory of slips for correction will perhaps place others of your readers, as it has myself, in a little difficulty as to how they should describe themselves in connexion with the Royal Society of Medicine. I believe that a Fellow of the late Royal Medical and Chirurgical Society *ipso facto* becomes a Fellow of the new Royal Society, but how is my partner to replace his "Fell. Obst. Soc.; Mem. Clin. and Path. Socs."? and how is one who previously belonged only to the Clinical Society to write himself down?

I am, Sirs, yours faithfully,

Sept. 9th, 1907. PUZZLED.

THE PUBLIC AND PRIVATE SLAUGHTER-HOUSES OF DUBLIN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PART I.

The Public Abattoir.

THE position of Dublin in regard to its slaughter-houses, public and private, is peculiar and somewhat perilous. *Under existing conditions there can be no serious guarantee* that the meat is properly inspected before it is sold for human food. On the other hand, the complications that have arisen are such that it is not easy to see how matters are to be arranged in a satisfactory manner without occasioning a good deal of friction and opposition. To put the case briefly, there were many private slaughter-houses in existence when the Dublin Improvement Act of 1851 became law. Since that date licences for slaughter-houses have been frequently granted, although they were accompanied with the stipulation that on the establishment of a public abattoir these private slaughter-houses should be given up. Ultimately a public abattoir was built, but it was placed on the county side of a road which divided the county from the city of Dublin. Thereupon the butchers contended that as the abattoir was not within the city they could not be made to go there and need not give up the temporary licences that had been granted to them on the conditions explained above. Either the butchers were right in law or the authorities supine in the matter, for the butchers were not forced to close their private slaughter-houses. In 1890, however, another Dublin Improvement Act was passed and then the boundaries of the city were extended, so that now the public abattoir is within its jurisdiction. In these circumstances it was naturally thought that the private slaughter-house licences would, as originally intended, come to an end. These, however, are technical matters. They do not come within the scope of popular, political, or theological controversy, and the great mass of the people at Dublin are not taught to study such purely practical and scientific problems. Therefore the handful of butchers who have a personal interest in the question are often able to act as if there were no other interests than their own to consider, because public opinion is too ignorant or too indifferent to exercise any check. Thus interested parties were able to bring influence to bear, so that the corporation of Dublin during the passing of the Act agreed to regard as permanent the temporary licences which it had granted. Instead of coming to an end automatically when the boundaries of the city were extended and included the public abattoir it was now stipulated that these licences could *only be extinguished* by purchase. Yet it cannot be said that these butchers had a vested interest since the licences were only given as temporary licences. It was known from the first that the butchers would be called upon to remove their slaughtering business to a public abattoir; nevertheless, *the ratepayers* are now to be called upon to give them compensation. But this is not all, for even if the money is forthcoming another difficulty arises. The Act insists that only one person can receive compensation in regard to the closing of a private slaughter-house and it is often a matter of *great perplexity* to determine who that one person should be. Thus it is that since the passing of the Act in 1890 only 18 private slaughter-houses have been closed, and, including some situated in three townships recently annexed to the city, there still remain in Dublin no less than 62 private slaughter-houses.

That it is necessary to do away with the private slaughter-houses can scarcely be questioned; it can only be urged that their abolition should be deferred till a very much better public abattoir is built than that which now exists. The situation is described by Surgeon-Colonel D. Edgar Flinn, medical inspector of the Local Government Board of Ireland, in his official report for 1906. He there states that about 70 butchers avail themselves of the public abattoir, killing there from 700 to 800 animals weekly. The average number of cattle slaughtered weekly is about 200, of sheep 450, of pigs 50, and of calves 6. On the other hand, the killing in the private slaughter-houses is approximately estimated at cattle 380, sheep 1671, pigs 739, and calves 20. Thus only about a quarter of the slaughtering takes place at the public abattoir; by far the greater part of the Dublin meat comes from private slaughter-houses. Many of these private slaughter-houses

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which *not only* affords a ready means of finding any notice but *is in itself* an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or *Subscriptions* should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

abattoir affords not only this but several other advantages. The slaughter-sheds, with all their faults, are better than many of the private slaughter-houses. There is better prospect that the meat will be properly inspected. Then there is a condemned meat department, so that what is unwholesome is promptly separated from what is fit to eat. The site also on which the public abattoir stands is on an elevation well exposed to the purifying action of all the four winds. The establishment could be easily improved and better discipline and greater cleanliness enforced. Though historic truth, and judging after seeing many model slaughter-houses on the continent, compels me to criticise and to find fault with the Dublin public abattoir, it nevertheless remains superior to most of the private slaughter-houses. The latter undoubtedly must be swept away, but it will be necessary at the same time to effect very great improvements in the public abattoirs that are to replace them. It *now remains for me to describe the condition of* some of the private slaughter-houses of Dublin.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Modern Surgery.

A GARDEN party was given at the Ashton-under-Lyne District Infirmary on Saturday last to mark the completion of improvements and extensions to the institution. Mr. William Thorburn, one of the surgeons to the Manchester Royal Infirmary, was amongst the guests and made some interesting remarks on the progress that had taken place in surgery even during the period of his connexion with the infirmary. 25 years ago the number of operations performed in a given time by one surgeon was 56, while now the number performed in the same time was 205. The deaths out of the 56 cases were 12; the deaths to-day out of the 205 cases were still 12. This is a striking reduction in the mortality after operation. He went on to speak of the still more striking advance in the surgical treatment of disease, particularly of the internal organs. 25 years ago five operations, which to day would be considered slight and which were more or less tentative, were performed in six months. Of the five cases two died, which would give a mortality of 40 per cent. To-day, in the same period, 73 such operations were performed, with a total of six deaths. Then, as regards the saving of limbs, among the comparatively small number of operations 25 years ago there were 16 cases of amputation, of which eight died; while at the present day, in the far larger number of operations, they had only eight amputations and no deaths. "Both the periods he had selected were since the introduction of anæsthetics and antiseptics and they simply represented the gradual outcome of a steady and persistent study of disease, the nature of disease; the means of recognising disease, the precise localisation of disease, and the organisation of the staff which has to deal with that disease in a great hospital. If there was one point more outstanding than another it was that in these 25 years they had trained everybody, every nurse, every charwoman who had to deal with the ward, to do their duty in the most thorough way, and to eliminate little sources of error which formerly used to crop up." Though Lord Lister's name is not mentioned in this passage, for his investigations have so much influenced surgical views and their results have been so dominant in shaping surgical methods, and have become so much an unquestioned and integral part of surgical science that the originator is almost liable to be forgotten, yet it bears testimony to the debt that surgery and indeed the whole family of man owe to the patient and in those days the difficult labours of one man. The stimulus given by the work and example of Lord Lister has had much to do with the infinite pains and watchful care that characterise the surgery of to-day.

The Sale of Poisons.

The careless way in which the sale of poisons is sometimes carried on leads from time to time to fatal results. An inquest was held at Rochdale on Sept. 7th on the body of a man who died from drinking ammonia from an unlabelled bottle. The coroner said that it was a dangerous thing to sell poison in this way and "he should report the matter to see if a stop could not be put to the indiscriminate sale of poisons." This is really an urgent matter, for though it may be said that the man owed his death to his own folly, it is no less a fact that many people require protection from the consequences of such folly. The verdict was the ordinary one—"Accidental death."

Drunken Jurymen.

An inquest was held last night at Bury on the body of a man who was hurt on a railway and died the next day, and the verdict was "Accidental death." The peculiarity of this inquest was, however, that the coroner is reported "to have tolerated the conduct of two of the jurymen but reprimanded them." They insisted on asking questions which the coroner, Mr. S. F. Butcher, said had nothing to do with the case. Eventually the interruptions led him to tell the jury that "If any juryman has had too much drink he will be wise to hold his tongue, because if he does not he will be fined." The first part of this utterance is of wide application, even where there is no fear of a fine. The coroner's officer said that the two men were sober at noon when he warned them to attend.

Fines for Adulteration.

Southport has long been famous for its shrimps and is sometimes scarcely able to supply the demand for potted shrimps without some outside help. Yesterday a local fish-dealer was fined 20*s.* and costs for selling potted shrimps containing an excess of boric acid. It was stated by the prosecution that the shrimps had 107·6 grains of acid to the pound, while the Commission that had inquired into the matter only allowed 85 grains to the pound. Another Southport tradesman was fined £2 yesterday. In this case it was for selling as butter a substance containing 90 per cent. of margarine.

Sept. 10th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Medical Session.

THE medical session will be opened by an informal "at home," to be held in the Medical School on the afternoon of Oct. 1st, when Major Ronald Ross, Professor of Tropical Medicine in the University of Liverpool, will present the prizes. Leeds is thus departing on this occasion from the custom of having an opening address. In the evening there will be held as usual the annual dinner of the medical profession of Leeds and district, when, in addition to Major Ross, there will be numbered among the guests the Lord Mayor of Leeds, Lord Airedale, and Professor Miall. Lord Airedale's interest in all that pertains to the welfare of the University is well known. He was one of the first of its honorary graduates, receiving at the inauguration ceremony the degree of D Sc. at the hands of Lord Ripon.

Leeds Sewage Disposal.

At a meeting of the Leeds city council held on Sept. 4th the following motion was carried without discussion:—

> That the council promote a Bill in the next session of Parliament to obtain compulsory powers of purchase of a portion of the Temple-newsam estate, not exceeding 600 acres, for the purposes of sewage disposal and to obtain such other powers as may be necessary to enable the council to carry out the scheme for disposal of the sewage of the city which has already been sanctioned by the council;

It will be remembered that at the recent assizes an order on the subject was made by Mr. Justice Grantham and this action on the part of the council is in harmony with the terms of the order.

The Supply of Water to Charitable Institutions.

A deputation, consisting of Mr. Charles Lupton and other members of the infirmary board, came before the corporation with respect to a proposal which had been made that the charge for water supplied to the infirmary should be increased from 3*d*. to 6*d*. per 1000 gallons. The proposal was a general one and it was intended to apply to all the charities and educational institutions of the city, but Mr. Lupton pointed out that the work of the infirmary was carried on without any support from the rates, that last year the expenditure exceeded the income by £4000, and that the infirmary was doing a great work which otherwise would have to be undertaken by the municipality. In his opinion the corporation should not expect to make a profit from the infirmary on the water-supply. He supported the request of conceive and carry out this daring project was one of your own countrymen.

Notwithstanding, however, Nature's adaptability the retention of gastric digestion undoubtedly adds to the resisting power of the individual in the struggle for existence. Personally I do not believe that loss of gastric digestion is a necessary consequence of a short circuit between the stomach and jejunum. Those who have expressed an opposite view base their conclusions on the subsequent diminution of chlorides found in the gastric contents. This argument is not conclusive, as the chlorides may be greatly diminished without the loss of gastric digestion. Further, unless atrophy of the mucous membrane is advanced owing to disease existing before operation, there is in my experience usually a progressive increase in the chlorides secreted during the digestion of a test meal. A more reliable indication of the extent of gastric digestion can be gained from an examination of the fæces. Schmidt has shown that only the gastric juice can digest *raw* connective tissue. I have on many occasions fed patients after gastro-jejunostomy on raw beef, but have never found any undigested connective tissue on microscopical examination of the fæces.

4. *The effect of gastro-jejunostomy on the motility of the stomach.*—Impairment of the motility of the stomach is a much more serious matter than impairment of its secretion, for it appears that the stomach, if its peptic power be reduced, endeavours to make up for the failure of digestive power by greater energy in moving on its contents. In these circumstances the food leaves the stomach incompletely digested, but this does not seem of serious import, for von Noorden maintains that the intestine can vicariously assume the peptic functions of the stomach. I have already pointed out that after gastro-jejunostomy some diminution of the gastric secretion occurs; if then it were the case that gastro-jejunostomy in addition impairs the motility of the stomach the usefulness of the operation would be considerably curtailed. Diverse views have been expressed on this subject. Hartmann and Soupault, Rydygier, and Rosenheim found the motility of the stomach permanently impaired; Carle and Fantino, on the other hand, maintain that the emptying of the stomach is hastened rather than retarded. It is, I think, possible that in such investigations the existence of impaired motility *before* operation has not always been excluded. Although motor insufficiency be present after operation, we cannot assume that the insufficiency is due to operation, unless we have shown the stomach to have been normal in this respect before operation.

I have now investigated the motility of the stomach before and after gastro-jejunostomy in a considerable number of cases, but I will now refer only to three typical examples. The first of these was a woman upon whom I performed gastro-jejunostomy for repeated attacks of hæmorrhage from a gastric ulcer. Examination before operation showed that on an average the stomach was empty three and a half hours after a test breakfast. Two months after operation a number of observations showed that the stomach was empty four hours after a similar test meal. You will observe that although the motility was slightly impaired by operation, the delay in evacuation did not exceed the physiological limits. This case raises the question, How does gastro-jejunostomy influence those cases of gastric ulcer in which the motility of the stomach is not impaired? I will return to this point later.

The second observation was carried out on a patient upon whom I performed gastro-jejunostomy for gastric tetany, with almost complete pyloric stenosis and greatly impaired motility. Two years after operation examination showed the stomach to be empty on two occasions four hours after a test breakfast, and on another occasion four hours after a full dinner only 25 cubic centimetres of fluid containing a trace of bile were drawn off.

Observations on a third patient showed that before operation 20 cubic centimetres of fluid remained in the stomach four hours after a test breakfast. One month after operation, at which a chronic gastric ulcer with dense adhesions to the abdominal wall was found at the cardiac end of the stomach, examination showed that on one occasion 15 cubic centimetres, and on another occasion five cubic centimetres of slightly green tenacious fluid, showing a faint Gmelin's reaction, remained in the stomach three and a half hours after a test breakfast.

From these and numerous other observations I think that we may conclude that, in those cases in which the motility is markedly impaired by pyloric stenosis or by adhesions, the operation of gastro-jejunostomy usually results in a marked improvement in the evacuation of the stomach contents. In those cases, on the other hand, in which before operation the motility is unimpaired, gastro-jejunostomy may either slightly retard or slightly hasten evacuation, but inasmuch as this retardation or acceleration falls within physiological limits, we are justified in saying that in cases in which the motility is normal before operation the evacuation of the stomach is for practical purposes unchanged by gastro-jejunostomy.

Is gastro-jejunostomy a drainage operation?—The observations on the motility of the stomach which have already been mentioned are against the view that gastro-jejunostomy is a drainage operation, and W. B. Cannon and J. B. Blake in their most invaluable article also put forward strong arguments against such a supposition. These writers too, from observations on dogs by means of the Roentgen rays, have come to the conclusion that in cases in which the pylorus is unobstructed the food continues to pass through the pylorus rather than through the new opening. Are we justified in assuming that this holds good for a human being if the anastomotic opening is made of large size? It is at least suggestive that in the only case in Cannon and Blake's series in which the food passed out through the anastomotic opening rather than through the pylorus the opening which had been made was a large one. This observation appears to me to be a most important one. It emphasises the necessity for a large anastomotic opening, which is in my judgment the most important point in the technique of gastro-jejunostomy.

To what are the beneficial effects of gastro-jejunostomy on gastric ulcer due?—Most writers have assumed that gastro-jejunostomy is a drainage operation and have attributed the beneficial effects of the operation on gastric ulcer to hastened evacuation of the stomach. If this be true it follows that in those cases of gastric ulcer in which motility of the stomach is normal the operation of gastro-jejunostomy would be of little or no avail. This has not been my experience. I have already told you of a case in which the motility was slightly impaired after operation. Notwithstanding this impairment the patient rapidly improved, lost all her gastric symptoms, and has remained ever since in excellent health. Indeed, some of the most striking successes I have witnessed have been in cases in which before operation there was no evidence of delayed evacuation of the stomach. We must, therefore, I think, look for some other factor than drainage to explain the influence of gastro-jejunostomy on gastric ulcer. There is a general agreement that hyperacidity is the factor which prevents healing of a gastric ulcer. After gastro-jejunostomy there is a marked diminution of the total acidity of the gastric contents, which diminution does not depend on improved evacuation. Are we not justified in assuming that it is to this diminution of the gastric acidity that the beneficial effects of gastro-jejunostomy on gastric ulcer are due?

II. The Effect of Gastro-jejunostomy on the Metabolism of the Human Body.

In the year 1897 Jöslin published observations on the metabolism of two patients upon whom gastro jejunostomy had been performed. He maintained that as the result of this operation there is a marked diminution of the proportion of nitrogen absorbed from the food and an even more marked diminution in the fat absorption. These conclusions have been accepted without question. In my book on Gastric Surgery published last year I gave details of observations on four patients in whom the absorption of fat and nitrogen was practically unaffected. There are still writers who dilate on the evil consequences of this operation and of the interference with the physiology of digestion which it entails. Two years ago a distinguished surgeon wrote: "It is improbable that so much interference with the anatomy and physiology of digestion as this operation involves can be tolerated without some ill effects." As recently as six months ago another writer remarked: "The interference with the physiology of digestion which such an operation entails is not well tolerated." He then pointed out the necessity for the existence of the acid medium of the stomach with its pepsin for the digestion of the fat cells and starch granules. I have already pointed out to you the evidence that connective tissue digestion continues after gastro-jejunostomy and I will now endeavour to prove to you from the further observations which I have made that these hypotheses

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Girgenti Home for Inebriates.

THE sixth annual report by the corporation of Glasgow to the Secretary for Scotland of the Girgenti Home for Inebriates states that there were 41 inmates in the reformatory on Dec. 31st, 1905, while up to that date there had been 113 admissions. During the year 1906 there were 17 new admissions, making the total number on the register 130. The medical officer has classified the patients as follows: hysterical patients, 18; weak-minded (moral paralytics), 17; accidental drunkards, 22; and chronic inebriates, 73. The largest number of inmates still comes from the lower grades of society, and as they have been "out and in" the poor-house for years they can be called "pauper inebriates." In connexion with chronic inebriates the medical officer is of opinion that a cure is highly improbable and very nearly impossible. It must be remembered that the majority of cases had been confirmed drunkards for a number of years, and when admitted were suffering from physical conditions the result of disease and accident. The treatment adopted in the reformatory is essentially the same as that adopted for mental disorders, and endeavours are directed not so much to stop the drinking of alcohol as to suppress the craving for it. Two years ago the medical officer in charge made trial of the drug treatment, which consisted of the administration of $\frac{1}{100}$th grain of atropine sulphate daily and also a mixture containing quinine, sodium, ammonium, and aloin. 22 patients willingly consented to undergo the treatment which was not, however, successful. The financial statement for the year shows that the expenditure (exclusive of expenditure on the farm and garden) amounted to £2628, equal on the average to £62 11*s*. 6*d*. per inmate per annum, or to £1 4*s*. per week. Of this weekly amount there were contributed by the Government 10*s*. 7*d*., by the corporation 12*s*. 10½*d*., and by sundry revenues 6½*d*. On the farm and garden account for the year there was a credit balance of £57 10*s*. 8*d*.

Deadly Concoction Drunk by Poles.

Some extraordinary revelations were made at a recent meeting of the Dalziel parish council with reference to the drinking habits of Poles, of whom there are in Lanarkshire a considerable number engaged in working as coal miners. It was stated that cases had been sent to Kirklands Asylum, chargeable to the parish, on account of their indulgence in a drink which was doing much injury among Poles in the district. The concoction was a mixture of methylated spirit, ether, and paraffin oil, and it was asserted that a thimbleful of it would do more injury to a man than a bottle of brandy. This drink is hawked through the streets and the sale of it does not seem to be a contravention of the Licensing Acts. It was decided to communicate with Mr. Findlay, M.P., to get the matter brought before Parliament with a view to putting down the traffic in this stuff.

Death of Mr. John Stuart Nairne.

I announce with regret the death of Mr. J. Stuart Nairne, F.R.C.S. Edin. and F.F.P.S. Glasg., which took place this week at his residence in Renfrew-street, Glasgow. Mr. Nairne, who was in his sixty-first year, has been in failing health for some time, and about a week ago, while on a visit to the country, he caught a chill which developed into his fatal illness. A native of Irvine, Mr. Nairne received his education in Glasgow, at first serving his apprenticeship as a pupil teacher but eventually turning his attention to medicine. At the close of his medical curriculum he began practice in Glasgow, his special interest lying in surgery. By frequent visits to hospitals at home and abroad he made himself acquainted with the most advanced methods of treatment and operation and latterly devoted himself chiefly to gynæcological work. For some time he conducted a gynæcology class for women in the Western Medical School. Impressed with the great amount of suffering among women he was the moving spirit in the foundation of the Samaritan Hospital which was inaugurated in Cumberland-street in January, 1886. Mr. Nairne was the first surgeon of the hospital and held office until 18 months ago when he was appointed consulting surgeon to the hospital. He took a great interest in the recent large extension of the institution and was present at the opening of the new section by Lady Blythswood in April last. On his retirement he was the recipient of a public testimonial, consisting of a cheque for about £300, a study chair, and of silver plate for Mrs. Nairne, the presentation being made by the Lord Provost. Mr. Nairne is survived by his wife, one son, and three daughters.

Lecture by Sir A. E. Wright at Glasgow Royal Infirmary.

The opening lecture of the autumn course of post-graduate classes in connexion with the Glasgow Royal Infirmary was delivered in the Dispensary Hall last week by Sir A. E. Wright. The Lord Provost presided and there was a large attendance of medical men. The subject of the lecture was "The Principles of Vaccine-Therapy," or a new method of treating bacterial disease. The present methods of treatment—antiseptics, extirpation, serum-therapy, and the expectant method—were all pronounced unsatisfactory by the lecturer and he proceeded to show the defect of each. He was sorry that so many surgeons were still satisfied with the extirpation method which really belonged to barbarism. It was quite ineffective, except, perhaps, in the case of the appendix, which could be taken right away. He then went on to describe the principles in detail of vaccine-therapy and predicted that it would form an important branch of study in the medical schools of the future.

The Sanitary Association of Scotland.

The Sanitary Association of Scotland held its annual meeting last week at Aberdeen and was able to demonstrate, to quote the words of the *Aberdeen Free Press*, that "it is not merely the pedagogue who calls the school to order and sets the old lessons anew; it also plays the part of pioneer in making fresh advances, and its conferences form a record of progress at once encouraging and useful." To the march of sanitation Scotland and the country at large owe a great deal, but there still remains much to be done to bring Scotland to the position in public health which the generally advanced condition of the country warrants us to expect. Dr. J. T. Wilson in his presidential address dealt with preventive measures against infectious diseases, the provision of hospitals for the isolation and treatment of those suffering from such diseases, and steps for restricting the dissemination of consumption. He took a broad view of the scope of the sanitary measures that were desirable to give the community its best chance of public health, and evidently believed that the public should be educated to understand the meaning of sanitary sin. An interesting feature of the proceedings was the discussion on cerebro-spinal fever, the declaration that the most effectual way of coping with it was to observe the elementary principles of sanitation being a clear indication of the value of the proceedings. Not merely public health authorities, who may be regarded as more immediately concerned, but the general public at large, whose health and happiness depend so largely on the adoption of effective sanitary measures, are thus taught the urgency of hygienic matters. Interesting papers were read to the congress by, among others, Mr. J. McLauchlan Young, lecturer in veterinary medicine at the University of Aberdeen, who read a paper on Meat Inspection; Dr. Matthew Hay, medical officer of health of Aberdeen, who discussed the inspection of fish; Mr. A. M. Trotter, veterinary inspector to the city of Glasgow, who dealt with the supervision of milk; and Dr. G. M. Cullen, who described the process of animal inspection in Edinburgh and spoke of the need of abattoirs. A paper read by the secretary of the congress for Dr. C. R. Macdonald, county medical officer of Ayrshire, upon the Supervision of Dairies led to an interesting debate, while a paper by the President upon the Training of Meat Inspectors also gave rise to a useful discussion.—The annual dinner of the association and a conversazione in the Art Gallery proved to be highly successful, and the officers of the association may be congratulated on having proved the value of the work of their institution.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Belfast Asylum.

THE report of the resident medical superintendent of the Belfast Asylum, Dr. W. Graham, for the year ended Dec. 31st, 1906, has just been issued. There were 241 admissions during the year, 1349 (626 male and 723 female) other surgical procedure short of the removal of the higher centres of their brains will cure such of their ills.

To sum up, we are, I think, justified in drawing the following conclusions as to the physiological effects of gastro-jejunostomy:—1. A certain amount of bile and pancreatic juice enters the stomach after gastro-jejunostomy but the amount is small and has no injurious effect. 2. The acidity of the gastric contents is markedly diminished, usually about 30 or 35 per cent. This is due, partly to a diminution of the total chlorides secreted, partly to the partial or complete neutralisation of the free hydrochloric acid by the alkaline bile and pancreatic juice, and probably also to earlier stimulation of the pancreatic secretion, and compensatory earlier fall of the gastric secretion. In gastric ulcer cases the removal of spasmodic stenosis of the pylorus likewise tends to diminish the total acidity. 3. Gastric digestion is impaired but not lost after gastro-jejunostomy. 4. The motility of the stomach, if normal before operation, is for practical purposes unaffected. Gastro-jejunostomy is therefore not a drainage operation. Its beneficial effects on gastric ulcer are due to the diminution of the acidity of the gastric contents. 5. Gastro-jejunostomy has no material effect on the metabolism of the human body, the percentage of nitrogen and fat absorbed being within the limits observed in individuals who are apparently healthy. This chemico-pathological evidence is supported by the evidence of clinical experience.

The technique and statistics of gastro-jejunostomy I do not propose to discuss. They have been recently fully dealt with in addresses delivered before this association. If you will allow, I should, however, like to bring to your notice two time-saving devices which I have found of great value. The first is this set of suture reels. Each reel is of a different length so that each size of silk or thread can be wound on a different sized reel; thus the surgeon is able to see at a glance without examination of the suture material which size of ligature he requires during the course of the operation. The other device is this pattern of needle, which may be called a "grip eyed" needle. It is designed to obviate the inconvenience and delay caused by the accidental unthreading of needles during suturing, and is especially adapted for continuous suturing. By pulling the suture firmly into the extremity of the eye furthest from the point the thread is firmly gripped so that it cannot slip out.

In conclusion, it is my pleasant duty to thank you one and all most cordially for the honour you have done me in inviting me to address this meeting of your association. Conscious as I am of the fragmentary nature of my remarks, I would remind you that just as "nature exists in leasts" so the science of medicine has been built up by the accumulation of little facts. I venture to think that the dry bones of the observations which I have put before you are in reality clothed with the interest of practical importance in the surgery of the stomach. Be that as it may, this at least I hope, that such visits as mine serve as an evidence of that good fellowship which should, and I believe does, exist between members of our profession in the old world and in the new. Although separated by the sea we are united in the brotherhood of our common art. May we each glory in the share the other takes in its advancement. Let us say, as Marcus Aurelius said of old, "what matter by whom the good is done." And here may I pay a tribute to those in your country, some of whom now no longer speak to us, who have played so great a part in the progress of gastric and intestinal surgery. To mention only a few of these, the work of Halsted and Cushing on intestinal suturing, the work of Murphy on intestinal anastomosis, and the brilliant results of the Mayos, Oschner, Deaver, Finney, and others are landmarks in the history of the surgery of the stomach. And let us not forget the early work of Senn, the father of intestinal surgery, and of O'Connor, whose conception and intrepid execution of the first total gastrectomy gave a powerful stimulus to gastric surgery. All honour to these early American pioneers. Let us strive to follow in their footsteps.

"Science moves but slowly, slowly, creeping on from point to point,
Men my brothers, men the workers, forward, forward let us range."

The science and art of surgery are incomplete and incompletable. We are aiming for a goal which we may never reach; but, as your great writer Emerson says, "The persuasion that we must search that which we do not know, will render us beyond comparison, better, braver, and more industrious, than if we thought it impossible to discover that we do not know, and useless to search for it."

RELATION OF POLYMASTIA TO MULTIPAROUS BIRTH.[1]

By DR. TEIZO IWAI,
PHYSICIAN-IN-CHIEF OF THE JAPAN RED CROSS HOSPITAL; ATTACHED TO THE SUITE OF H.I.H. PRINCE FUSHIMI REPRESENTING HIS MAJESTY THE EMPEROR OF JAPAN.

IT is a general truth that the number of offspring in mammalia usually corresponds to the number of nipples. Horses and sheep having a single pair of nipples commonly have but a single offspring, while pigs, having five or six pairs, bear from six to 12 offspring at one birth. Dr. Ch. Ishikawa (professor of zoology, Tokyo Imperial University) told me that Mr. Graham Bell, the inventor of the telephone, noticed once while keeping sheep that some of them had more than one offspring, and that the same ones again gave multiparous birth at the next period of parturition. So he set them aside for breeding. Later, as he found that these sheep had supernumerary nipples, he began to set aside all the sheep with the supernumerary nipples for breeding, and he was very successful in his experiment. These facts seem to support the old saying that those who have supernumerary glands bear twins or triplets. Many European scholars, however, do not agree with this. Dr. R. Bonnet said that although he had no opinion of his own in regard to the relation of polymastia to multiparous birth based upon sufficient evidence, yet according to Dr. Leichtenstern out of 70 women who were subjects of polymastia there were only three who gave birth to twins. Dr. R. Wiedersheim, upholding the opinions of various scholars that polymastia is not associated with twin-birth, cited also the example above-mentioned.

According to Wappäus, Meckel, Veit, Hildebrand, Konrad, Ruppin, and others, however, the proportion of twin births in Europe, although it varies according to different writers, is, roughly speaking, 1·37 per cent. If this is the case, what Dr. Bonnet cited, three cases of twins out of 70 women subjects of polymastia as proving that there is no relation between polymastia and twins, goes to verify exactly the opposite of what he intended. That is, three cases out of 70 is 4·28 per cent., or more than three times the ratio of twins among ordinary women. I can add to this another example given by Dr. Hansemann, that of a woman who had supernumerary mammary glands and who became pregnant 17 times, twice giving birth to twins. Dr. Hugo Goldberger states that he had observed the case of a woman, 32 years of age, having one supernumerary gland in each axilla, who gave birth five times, the last of which was a case of the abortion of twins in the sixth month.

I have not yet had an opportunity of gathering the statistics of twins in this country. I have, however, applied once to Mr. N. Hanabusa, Chief of the Bureau of Statistics, to be provided with such statistics, but have been informed by him that owing to the incomplete state of our present census satisfactory statistics relative to twin-births have not yet been completed. I am therefore obliged to mention in the following table only those facts which I have been enabled myself to gather up to the present.

Observers	Cases of parturitions	Cases of twins.	Per-centage.	Cases of triplets.	Per-centage.
Dr. S. Kinoshita and Dr. K. Morimune.	1728	21	1·21	1	0·05
Dr. E. Omori	523	3	0·57	—	—
Dr. K. Arai.	160	1	0·63	—	—
Mrs. N. Iwasaki (a midwife).	1092	4	0·36	—	—
Miss T. Hisajima (a midwife).	539	3	0·55	—	—
Mrs. K. Yoshino (a midwife).	787	6	0·76	1	0·12
Miss I. Yabe (a midwife).	263	4	1·52	—	—
Total	5092	42	0·82	2	0·03

Putting the above seven returns together we have the average of 0·82 per cent., which is 0·55 per cent. less than the ratio of twins in Europe (1·37 per cent.). Though I am not the case of adults. An immediate correction might no doubt be obtained by partial resection of the tibial epiphysis, but the ultimate results would be disastrous, for this cartilage was necessary for the natural growth of the bone and interference with it would lead to a shortening of six or eight inches in the patient's lower limb when adult life was reached. Moreover, when the ankylosis was divided in the usual way two flattened surfaces were produced which could not be brought into satisfactory apposition when the limb was straightened. M. Lardennois avoided this difficulty by making a curved incision with Gigli's wire saw; the opposing curved surfaces obtained in this way presented a considerable area of contact and firm union might be expected.

Wounds of the Eye Caused by the Bursting of Bottles.

At the same congress M. A. Bourgeois read a paper on the treatment of wounds of the eye caused by the bursting of bottles. He said that on account of the thickness of champagne bottles the fragments produced by their bursting were usually of considerable size, and the wounds which they caused were proportionately extensive and serious; the bruising effect of the flying glass caused the edges of the wounds to be irregular but no glass was left in them. He had found that suture of the cornea or of the cornea and sclerotic gave excellent results when performed soon after the infliction of the injury. Seriously wounded eyes were invariably enucleated 20 years ago but the improved methods and instruments of modern surgeons frequently avoided the necessity for enucleation, to the advantage of the patient's appearance and in some cases a certain amount of visual power was retained.

French Ambulance Work in Morocco.

Dr. Henri de Rothschild has just started for Tangier to organise there an ambulance service for the wounded from Casablanca. With him have gone two other medical men and two nurses (*surveillantes*). The Red Cross Society (Société de Secours aux Blessés) has also organised an ambulance with the authority of the Minister of War. The general secretary of the society has started for Tangier where he will confer with the French Minister to Morocco. The ambulance will consist of 100 beds and the staff of 18 nurses, eight male and ten female.

A Gift of 4,000,000 Francs.

The Red Cross Society has just received an anonymous gift consisting of the estate of Mont des Oiseaux at Hyères. The estate includes a park of 80 hectares, terraces, gardens, a house containing 120 rooms and five villas scattered through the grounds, the whole being valued at 4,000,000 francs. The society is going to make it a convalescent home for sick and wounded officers. The anonymous donor has also given a sum of 100,000 francs for upkeep.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Hospital Accommodation in Rome.

THE Administrative Board of the Roman Hospitals has this year been confronted with the problem of hospital accommodation in an acute form, for which a prompt remedy has become an absolute necessity. The overcrowding which for many years has prevailed in the wards of all the hospitals has lately been greatly aggravated through the demolition of part of the Hospital of Sant' Antonio on the Esquiline Hill to make room for the new Via Napoleone III.; by the removal of a wing of the Hospital of Santo Spirito to allow of the systematisation of the adjoining part of the Tiber near the Bridge of St. Angelo; and, finally, by the increase of the population of the city, which augments the number of patients seeking admission to the hospitals by about 400 every year. Whilst in London there is an outcry over the cost of maintaining empty beds, here in Rome the complaint is very different, as will be understood by a glimpse at any of the wards of such hospitals as Santo Spirito or San Giovanni. In the latter, for example, one of the wards on the ground floor contains 150 beds arranged in four rows with scant room between and every bed with its occupant. And for each bed that becomes vacant there are always dozens of applicants. With such a state of affairs already existing and the certainty in view that with the advent of winter the number of patients demanding admission will be greater still, no time was to be lost in providing additional accommodation. To meet the most pressing needs the board has ordered the immediate erection on a site contiguous to the hospital of San Giovanni of ten of the transportable hospitals known as the "Döcker," many of which are used by the Red Cross Societies in Germany and elsewhere, and of which there are already two in Rome at the Lazaretto of Santa Prisca. These "Döcker's barracks" are a Swedish invention, and are 22 metres long by six metres wide; they consist of a single storey and have a double wall of wood lined with "enamelled" cloth, and a waterproof roof made of wood and cloth, or cardboard and cloth. Each contains 22 beds. It is hoped that they will all be erected by the end of the year. Their cost will be 120,000 lire (£4800). At the same time the foundations are being laid, on a site between San Giovanni and the Via Merulana, of six new permanent hospital pavilions of two storeys each, with a large ward on each floor capable of taking 30 patients. When these are all completed some 600 additional beds will be available for the reception of patients, a provision which will give at least temporary relief to the present congested state of the other hospitals.

Outbreak of Tetanus at Bologna.

The surgical clinic of the University of Bologna has been closed on account of the numerous cases of tetanus which have appeared amongst the patients there.

The Moderate Use of Wine.

The controversy as to the use of alcoholic beverages has diffused itself over the continent, the Latin countries in particular. In Italy it still shows animation, though the *Giornale Vinicolo* (Wine-growers' Journal) is not perhaps the best medium through which the arguments *pro et contra* might be addressed to the public. These, however, are all from clinical teachers or consultants whose impartiality is beyond question, and there could hardly be a better "authority" to open the discussion than the Senator Giulio Bizzozero, whose loss to science is deplored far beyond the subalpine schools of which he was an ornament. Insisting on the wine in daily use being the genuine juice of the grape with which the "manufacturer" has as little as possible to do, he sees only good to be derived from it if taken in moderation—that is, in quantities adjusted to the physical and mental wants of the consumer. So used he has found it to brace the mind for its regular work, giving a sense of confidence as well as support to the faculties. Next comes the all-accomplished professor of physiology in the same school, Dr. Angelo Mosso, who is convinced that wine, within the limits laid down by Bizzozero, is a nutrient to the system, slowing or diminishing waste. Having placed this fact in physiological evidence, he cites the experience of the Prussian army which in the severe campaign of 1870–71 maintained its health in augmented proportion as it was quartered in ever greater force in a wine-growing country. Those in its ranks who belonged to total abstinence societies were found less able to stand the fatigues and privations of the march or the trenches than their comrades who drank in moderation the "bottled sunshine" of the Loire. Dr. Augusto Murri, professor of clinical medicine in the University of Bologna (whose contributions to THE LANCET on cerebral pathology are still referred to by workers in that field), is of opinion that the graduated use of wine is not hurtful; on the contrary, by reason of its adjustment to the individual's needs, it is distinctly wholesome. His long and varied clinical experience warrants him in saying that men who have used wine freely in their work, professional or other, maintain a high degree of vigour even in old age and that it would be more in accordance with true science to assert the value of wine, moderately used, than to condemn it *simpliciter*. Dr. Bonaventura Graziadei, who holds the chair of medical diagnosis in the University of Turin, is as clear as any of his colleagues on the subject. "Alcohol," he says, "is a necessity for man. All races possess their stimulating beverages. Of these wine is the prototype and I am convinced that its moderate use is beneficial." To the same effect may be cited the opinion of the Senator Achille De Giovanni, professor of clinical medicine in the University of Padua, while Dr. Alessandro Lustig, who occupies the chair of general pathology in the Istituto di Studi Superiori at Florence, says he finds "a glass of sound wine not only agreeable to the palate but useful to the organism." Dr. Cesare Lombroso is a woman in my vicinity who has supernumerary glands and had twins three or four years ago. She is really blessed with children, having ten in number, though she is but 35 years of age."

CASE 24.—Mrs I—— Y——, 25 years of age She gave birth to twins in 1900 when she was 22 years of age; before and after that time she had three children, making in all five. Upon examination no trace of polymastia could be found.

The weight, the height, and the circumference of head of the children mentioned in the above cases, so far as obtainable by me, are given in the following table:—

—	Order of birth.	Weight (kilogramme).	Height (cm.).	Circumference of head (cm.).	Remarks.
Case 1. Quintuplets.	1. Male.	1 125	36·4	25 8	Taken by Dr. M. Sato and Dr. K Sato; the date is unknown but having died four days after their birth this, must have been taken within these four days.
	2. Female.	1·125	34·9	26·1	
	3. Male.	1·575	38·2	27·2	
	4. Female.	1·387	37 8	26 4	
	5. Male.	1·347	36·4	27·2	
Case 2. *Triplets.*	1. Male.	2·300	43 0	31·0	Taken by Dr. K. Kusada four days after their birth.
	2. Female.	2·000	41·0	29·0	
	3. Male.	1·550	40·0	28 0	
Case 3. Triplets.	1. Male.	1·700	42·0	30 5	Taken by Dr. T. Iwai 13 days after their birth.
	2. Male.	2·000	46 0	31·5	
	3. Male.	2·300	46·0	33·0	
Case 5. Triplets.	1. Male.	1·980	47·0	31·0	Taken by Dr. T. Iwai six days after their birth.
	2. Male.	1·750	43 0	30·5	
	3. Male.	1·640	44·0	29·5	
Case 9. Triplets.	1. Female.	1·250	35 0	28·0	Taken by Dr. T. Iwai five days after their birth.
	2. Female.	*	*	*	
	3. Female.	1·480	38·0	28·0	

* Unable to examine, as the child died on the fourth day after birth.

Referring to the 17 children mentioned in the above table the lightest weight is 1125 grammes, as found in the second (female) child of Case 1, and the heaviest is 2300 grammes, as found in the third (male) child of Case 3 (taken, however, 13 days after his birth). The average weight is 1656 grammes. When we compare this figure with that of the average weight of the ordinary newly-born Japanese children —i.e., 2780 grammes—as taken by Dr. T. Miwa, the professor of the Medical College of Chiba, we find between them the difference of 1124 grammes. This will sufficiently show how incomplete is the development of the children of multiparous birth.

It is especially interesting to note the connexion between blood relation and multiparous birth, as, for example, in Cases 16 and 17, a woman and her younger brother's wife had twins in the same month of the same year; in Case 22 we find that Mr. N——'s aunt and her daughter (namely, his cousin) had twins; in Case 1 I found that the cousin and the cousin's daughter had twins alike. And in Case 3 only I found multiparous birth repeated in one and the same person. I have also noticed several cases of inheritance of polymastia, which I have already discussed in my essay, "A Statistical Study on the Polymastia of the Japanese."[3]

In the cases mentioned above we find that the youngest woman was 22 years of age and the majority of them were over 30 years and with the exception of Cases 5, 11, and 18 all had gone through labour several times. Thus, multiparous birth is found generally in women who had previously several children. This fact seems to coincide with Dr. Rump's opinion, that "the instances of the multiparous birth generally increase in women of advanced age, and in those who have gone through labour several times."

According to my observation those who have had more than triplets at a time are found among people who live very poorly, and also in their disposition, with the exception of one or two cases, seem to have certain features in common. They are generally of a mild temper and possessed of rather dull sexual passion; they are rather fleshy, and are commonly members of large families. This is in accordance with a popular saying that "poor people have a large number of children." Although I am aware that such minor points have no direct scientific bearing upon the subject under discussion I simply mention them in passing, having noticed them in my investigation of numerous cases.

CONCLUSION.

1. It is probable that there is a relation between polymastia and multiparous birth.

2. It is probable that those who have supernumerary mammary glands have a tendency to become more frequently pregnant than those who have not.

3. The fact that the instances of multiparous birth increase in women with the number of their conceptions and the development of their age coincides well with the opinions given hitherto by several eminent scholars.

4. According to my own observation the instances of multiparous birth are found more among people of the lower class, and especially among those of a low order of intelligence.

MUCOUS COLITIS.*

BY ERNEST HENRY HARRISSON, M.D. CANTAB.,
LATE MEDICAL CLINICAL ASSISTANT TO OUT-PATIENTS AT THE LONDON HOSPITAL.

MANY papers dealing with mucous colitis have recently appeared both on the continent and in England, and a careful perusal of the literature shows that the various authors hold views of a most diverse nature with regard to this interesting disease. There is hardly a disease known which has been favoured by so many different names. Thus it has been called by the several authors of papers on the subject membranous colitis, colica mucosa, muco-membranous entero-colitis, mucous colitis, enteritis membranacea, glairy enteritis, mucous colic, tubular diarrhœa, glutinous diarrhœa, intestinal croup, &c. Perhaps of these mucous colitis is the best term. Although this disease is not characterised by any active inflammatory process in the colon, yet there seems to be an over activity of the mucous cells in the lining of the large intestine associated with in some parts atony, and in other parts spasticity, of the muscular coats of the colon. Moreover, the chief characteristic of the disease is the passage of mucus which has peculiar properties of its own, and although the mucus casts may closely resemble membranes on a cursory examination, yet they are not really membranes, and therefore the term "membranous" is certainly misleading and should only be applied to cases in which true membrane is passed.

On perusing some of the recent dissertations on the subject one cannot help thinking that the great diversity of opinion, alike with regard to the etiology, symptoms, pathology, and treatment, arises from errors in diagnosis, and that many of the cases, described as mucous colitis, are not really true cases of the disease we are considering but are rather cases in which mucus is passed from the bowel as a result of some definite inflammatory condition of the colon or of the irritation caused by a growth in the large intestine. In my selection of cases I have been careful to exclude all those patients who have shown signs of ulceration of the colon, or of any other local condition, which may have given rise to symptoms closely resembling those which I shall describe later, and so the total number of cases is not large. Still, as mucous colitis is not a common disease, valuable conclusions may be drawn from a careful study of the 25 cases. Mucous colitis may be defined as a combined secretory and motor neurosis of the large intestine associated with abdominal pain which is of two kinds: a more or less constant aching pain felt chiefly in the lower part of the abdomen

---

[3] THE LANCET, Sept. 14th, 1907, p. 756.

* Thesis for the M.D. degree of the University of Cambridge

Obituary.

TIMOTHY HOLMES, M.A., M.C. CANTAB., F.R.C.S. ENG.,

LATELY VICE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; FELLOW OF PEMBROKE COLLEGE, CAMBRIDGE; CONSULTING SURGEON TO, AND JOINT TREASURER OF, ST. GEORGE'S HOSPITAL.

WE deeply regret to record the death at the advanced age of 82 years of Mr. Timothy Holmes, senior consulting surgeon to, and until recently joint treasurer of, St. George's Hospital. We have lost in him one of the great figures of Victorian surgery. Although he was but a name to those who have joined our ranks since 1887 or so, for a quarter of a century before that date he was ranked by universal opinion among the leaders of his science, appealing to the practical man, the educational expert, and the scientific surgeon alike by the range of his knowledge, the breadth of his views and his power to express them clearly.

Timothy Holmes was the son of a London merchant who died while his children, two sons and a daughter, were still quite young. He was educated at the Merchant Taylors' School, and later at Pembroke College, Cambridge, where he took one of the best degrees of his year, 1847, being thirteenth classic and also a wrangler. From Cambridge he proceeded to St. George's Hospital, where the leading members of the honorary staff at the time were Dr. Bence Jones, Mr. Robert Keate, and Mr. Cæsar Hawkins, the last two attaining to the post of President of the Royal College of Surgeons of England; the junior physician was Dr., now Sir Henry, Pitman who still remains among us; while Dr. Handfield Jones and Mr., afterwards Sir, Prescott Hewett were demonstrators of anatomy and physiology in the medical school. Holmes having decided to be a pure surgeon proceeded at once to the examinations for the Fellowship, passing the final in 1853 and never being a Member of the College. He was marked out from the first by his intellectual attainments for a place upon the staff, and after a brief interval, during which he served the usual offices of demonstrator of anatomy and surgical registrar, he was elected assistant surgeon to the hospital. In 1868 he became full surgeon, a post which he held until 1888, his time of office having undergone special extension. On the expiration of his surgeoncy he was elected consulting surgeon and also accepted the onerous and thankless task of treasurer, being associated in an honorary capacity in this post with the late Duke of Westminster. When at length he resigned this office he had worked for 50 years for the institution, and during the whole of that unusual period the impression which he had first created never varied—all his colleagues, his seniors and his juniors, saw in him a just man, one whose great intellectual capacities would never be used in a narrow or selfish way, the very type of a professional leader and the ideal friend for those who had their way to make.

Holmes's connexion with the Royal College of Surgeons of England was a long one. In 1872, 1873, and 1874 he was Hunterian Professor of Surgery and Pathology, and delivered at the College an extended series of lectures on the surgical treatment of aneurysm which confirmed the impression already conveyed by his literary work that he was a great expositor of his science and art. In 1829 and 1830 George James Guthrie had delivered the Hunterian Lectures on the same topic, and Holmes reviewed the whole subject in the light of the surgical development that had occurred during the intervening 40 years, bringing to the assistance of his great critical faculty the pen of a finished scholar. It was probably the success of these lectures which decided him to write his well-known "Treatise on the Principles and Practice of Surgery," though his literary capacity had been already exhibited in his work as general editor of, and contributor to, Holmes's "System of Surgery, Theoretical and Practical," a second edition of which was called for during his professorship at the College. In 1873 he was elected, together with John Marshall and Luther Holden, both of whom afterwards occupied the Presidential chair of the College, to the court of examiners; in 1877 he became a Councillor, being later elected a Vice-President of the College. It must be taken for granted that nothing but his own wish and action deprived him of the Presidency, for if ever an officer of the College had a claim upon that position by dignity of character, by force of intellect, and by quality of work it was Timothy Holmes.

Holmes's literary work made his name a familiar one to the surgeons of the world during his professional career. During 1860 and the four following years there appeared his "System of Surgery, Theoretical and Practical," an encyclopædia to which treatises were contributed by such recognised masters as Sir John Simon (inflammation), Sir James Paget (wounds, tumours), Sir William Savory (scrofula, collapse), Sir Thomas Longmore (gunshot wounds), Sir Prescott Hewett (injuries of the head), Sir William Jenner (skin diseases), Lord Lister (anæsthetics, amputations), Sir George Humphry and Sir Henry Thompson (diseases of male organs of generation)—to mention a few prominent contributors under the titular style which they later received, together with the subjects on which they wrote. It speaks much for Holmes's rising reputation as surgeon and scholar that he should have been chosen for the general editorship of such a work and should have found such a group of collaborators ready to assist him, for he was not yet assistant surgeon to St. George's Hospital when the scheme of the work was projected. His own contributions to the encyclopædia were the articles upon accidents from burns and lightning; upon dislocations, aneurysm, and diseases of the bone; upon excision of bones and joints; and upon the surgical diseases of childhood, the last being issued as an appendix. The System did not receive an enthusiastic welcome at first; the difficulties of joint-stock production had hardly been anticipated, and the authors found themselves cramped by the fear of repeating what others had said, or of anticipating what others were about to say. The various essays were not all written with identical conscientiousness and the general impression first produced in the surgical world seems to have been one of sympathetic disappointment. But undoubtedly the day had already gone by when it was possible for one author to write a complete system of surgery from his own personal knowledge; and after allowance had been made for the defects that must be inherent in production upon a scheme of collaboration the System was seen to possess a design and an execution which did honour alike to the general editor and his publishers, Messrs. Longmans and Co. It is possible that the comparative youth of the editor did not allow him in the first instance to be as resolute with his contributors as an older man would have been, but if Holmes spared his friends in the course of the issue of the System he certainly did not spare himself. The closing sentence of several long reviews in our columns upon the various volumes of the System as they appeared runs as follows: "Taken as a whole it is the most important surgical work which has ever issued from the English press. It is a great honour to a surgeon, comparatively young as is Mr. Holmes, to have been intrusted with the editing of so great a work; but now that it is completed it is only fair to say that he has executed the difficult task with ability, fidelity, and judgment. His own personal contributions are of a high order and both in choice of authors and arrangement of subjects there seems rarely any fault to find." A second edition of the System appeared ten years later. Sir John Simon's classical article upon inflammation is now supplemented, or rather replaced, by an essay from the pen of Burdon Sanderson, in which the foundations of modern pathology are revealed, while Lister gives a full account of the antiseptic treatment of wounds. Holmes may have learned his surgery too soon and may have entered the physiological laboratory too late ever to have become familiar with the details—chemical, physical, and bacteriological—a knowledge of which such essays implied; but he was far too great an observer and far too great a surgeon, both as scholar and clinician, not to see at once that the science and art of surgery were going to be revised from top to bottom and that the System of Surgery must be altered thoroughly from cover to cover, or must be expected to hold the field only until the new learning had produced a comprehensive literature of its own. The third and last edition of the System appeared in 1883, Mr. J. W. Hulke being most happily associated with Holmes in the editorship. The contributions were now differently arranged, owing to which rather than to compression the material was all included in three volumes. The interval of ten years or more necessitated the re-writing of many of the essays as well as the introduction of new authors, prominent among whom may be mentioned Mr. A. E. Barker, Mr. H. T. Butlin, Sir William Dalby, Mr. Rickman Godlee, Mr. Warrington Haward, Mr. Henry Morris, and Sir Frederick Treves. Holmes himself largely re-wrote his original contributions, and the result was an disease, and Rothmann,[11] Ruge,[12] Edwards,[13] Osler,[14] Jagic,[15] and Weigert[16] have performed necropsies on such cases. In every instance the examination was negative with regard to the bowel. Franke's case, on which a colotomy was performed, also confirms the view that the disease is in no way associated with morbid conditions of the colon. Abercrombie describes a case where there were cysts of the mucous membrane of the bowel. Von Noorden[17] states that there are a number of valuable post-mortem examinations on record that demonstrate positively that a disease picture corresponding to colica mucosa may actually be observed in cases of genuine enteritis. Boas[18] holds the view that these positive findings are of greater importance than any negative findings. This cannot in reality be so, for it is much more important that mucous colitis can be present without any anatomical lesion in the bowel, but occasionally is met with where there is definite evidence of inflammation. Nothnagel[19] recognises this and divides mucous colitis into two varieties—namely, enteritis membranacea and colica mucosa. This is certain, that an examination of the mucus passed fails to reveal any macroscopic or microscopic evidence of inflammation, and therefore the majority of the cases of this disease belong to the disease described by Nothnagel as colica mucosa. A few cases may certainly show the disease-picture of mucous colitis and suffer from a *definite enteritis in addition. H. Westphalen*[20] *opposes* Nothnagel in his classification of mucous colitis and his conclusions are: 1. The division of the so-called enteritis membranacea into two groups of different etiology, as Nothnagel does, into membranous enteritis, the result of intestinal catarrh, and into colica mucosa, an intestinal neurosis, can scarcely be maintained. All cases of the disease show a single etiological factor. 2. The membranous casts are formed in the intestine from a nervous supersecretion of mucus. 3. If there is an uncomplicated secretion neurosis large quantities of amorphous mucus are passed. 4 If in addition there is spastic constipation the over-abundant quantity of mucus is compressed and long tubular casts are passed. 5. If the masses are passed with severe pain he assumes, with Rosenheim, that a neurosis of intestinal sensibility exists at the same time. The mucus which is passed is hyalin, and embedded in it may be seen fæces, leucocytes in small numbers, and remains of undigested food particles, but no fibrin. The mucus differs from that of other intestinal diseases in that it contains fewer cellular elements, and also must possess certain peculiar properties, for it is more tough and tenacious and clings to the bowel wall more than ordinary mucus, so that it is with difficulty removed by means of the ordinary post-mortem hydrant.

To explain this peculiar property of the mucus von Noorden[21] has put forward two hypotheses. *He says*: "*It* is possible the secretion of mucus occurs under the stimulus of nervous irritation and that it is, from the beginning, constituted differently than normal mucus—i.e., it is more sticky"—and he illustrates this hypothesis by the comparison with the physiological experiment on the dog—namely, "stimulation of the chorda tympani produces an abundant secretion of thin watery saliva, whereas stimulation of the sympathetic produces a very thick tough gelatinous and stringy mucous secretion." His second hypothesis is that, "owing to the constipation produced by the spastic condition of the bowel, the fæces and mucus move very slowly along the large intestine, and absorption of water takes place from the mucus, and so it loses its motility and becomes less elastic, whilst its plasticity and stickiness increase, and when these properties of the mucus reach a certain degree the adherent masses can only be removed by violent contractions that are usually accompanied by pain, and so an attack may be brought about. The attack is determined either by the mass of the mucus or possibly by some chemical changes taking place in the mucus leading to irritating products (these chemical changes being little understood), or by certain nervous influences."

By careful consideration of all the facts before us it is fair to assume that mucous colitis is due to a disease of the nervous system consisting of a secretory and motor neurosis. Where the pain is excessive a sensory neurosis exists at the same time. To summarise the evidence that mucous colitis is a neurosis: 1. (*a*) The sex, age, and social position of the sufferers have to be considered. Thus the majority of the patients are females between the ages of 20 and 40 years, all more or less belonging to the middle and upper classes, and the majority manifesting various nervous phenomena. (*b*) The attacks of mucous colitis are frequently induced by excitement or emotion of any kind. (*c*) The almost total absence of any inflammatory condition in the colon. This also serves to disprove one of von Noorden's theories as to the causation of the pain—namely, that chemical changes may occur in the mucus leading to irritant products. If this were so these irritating products would most certainly cause some signs of inflammation in the mucosa of the colon. This is certainly not commonly the case. 2. Constipation and enteroptosis cannot be considered causative factors but only associated conditions. 3. The frequent association of other abdominal disorders, such as affections of the uterus and its appendages, true appendicitis, gall-stones, and abdominal aneurysm. Tuttle[22] quotes six cases where he discovered this condition present. 4. The disease can hardly be said to be caused by adhesions between the colon and surrounding structures, for this would not produce the nervous phenomena, which are protean in type. 5. The close analogy to asthma. In that in a *predisposed person* a small focus of nasal irritation will produce asthma, so also in a patient with a nervous diathesis a focus of abdominal disturbance, manifold in type, and often slight in character, will produce the symptom-complex of mucous colitis, this peculiar instability of the nervous system resulting in a combined secretory, sensory, and motor neurosis in the colon.

The symptomatology of mucous colitis is best studied by considering first the symptoms of the patient during an attack; and secondly, the symptoms between the attacks. The cardinal symptoms during an attack of mucous colitis are the passage of mucus and abdominal pains. The characters of the mucus passed vary according to the length of time it has remained in the bowel since its formation. Thus if it is soon passed, after being secreted by the mucous cells in the colon, it resembles the uncooked white of egg or frog's spawn and so is clear, colourless, and homogeneous. If it has remained some hours in the bowel the mucus becomes more intimately mixed with the other intestinal contents and also may appear in shreds of varying thickness and length. If it remains still longer in the large intestine before being passed it may be rolled up into round masses which, on careful examination in water, can be seen to be long pieces varying in length and thickness. In one of my cases I have seen such a piece unrolled which measured from 14 to 15 inches in length and one half to three-quarters of an inch in thickness. When the mucus is passed in these long strands it is nearly always discoloured by the fæces and frequently small round scybalous masses are found firmly adherent to the mucus, and occasionally small streaks or even clots of blood can be seen clinging to it. The microscopic examination of the mucus shows fæces and portions of undigested food particles together with, occasionally, red blood corpuscles and a few leucocytes embedded in a clear hyaline medium. Besides the mucus which is passed, hard fæces in scybalous masses form the greater part of the stools. For these patients are nearly always constipated (84 per cent.). In a great many instances undigested particles of food can be seen, especially when the patients have eaten vegetables or fruit which Melæna is contains a large percentage of cellulose. occasionally met with; thus, 36 per cent. of my cases have at some time or other during their illness passed blood with their stools. The amount varies considerably in quantity in different patients and at different times. In a few instances it can be seen that the bleeding proceeds from hæmorrhoids, since these are extremely common in patients who suffer from mucous colitis and are most probably caused by the constipation. Fæcal material is not always present in the stools of these patients, for I have frequently seen stools which have been accompanied by violent pains con- sisting of mucus only or mucus mixed with a little blood. Intestinal sand is occasionally passed in the motions, and in one of my cases recently there was quite a tablespoonful

TIMOTHY HOLMES, M.A., M.C. CANTAB., F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

there is much flatulent distension of the colon the addition of half an ounce of oleum terebinthinæ to the enema is useful. Irrigation of the colon certainly helps in the more rapid separation of the mucus from the walls of the intestine; and for this purpose ordinary warm water may be used at the temperature of the body, the injection being carried out by means of a funnel and a large sized indiarubber catheter passed through the anus and gently carried higher as the water is poured in, as by this means the rectum is distended and so the point of the catheter is not so likely to get caught in the folds of the mucous membrane of the intestine. At least two quarts of warm water should be employed at each injection. Various substances have been recommended to be used in solution for these high injections, such as sodium bicarbonate, sodium chloride, protargol 1 per cent., and silver nitrate ½ per cent., gradually increased in strength; but during the height of the attack it has been my experience that plain warm water affords the greatest relief, and afterwards one of the above solutions may be used once a day to prevent, if possible, the further hypersecretion of mucus. The patient should be kept in bed so long as the pain and passage of mucus continue and hot applications to the abdomen should be used freely. For this purpose flannels wrung out in hot water, and a few drops of turpentine or liquid extract of opium or the tincture of belladonna sprinkled on. These hot applications certainly afford a sense of comfort and give a feeling of relief on account of their antispasmodic tendencies, and so relieve the irregular peristalsis to a certain degree.

With regard to diet during the height of the attack nothing should be given for the first few hours until the more urgent symptoms have been relieved and then small quantities of milk, previously peptonised, may be given, the quantity being gradually increased as the patient improves. Many authors have recommended the use of opium or morphine during the height of the attack but I think that these drugs should not be employed for the relief of pain in this disease because their use will certainly check the peristaltic contractions and will increase the already existing constipation; and, moreover, as the persons who suffer from mucous colitis are nearly always of a neurotic temperament they are also persons who would speedily develop a habit and so would always seek relief from pains of a most trivial character in drugs of this description. Of late years in obstinate cases operations have been much recommended with a view to giving rest to the colon in the hope that by so doing a complete cure might be the result.

The operations which have recently been tried are two in number. The first consists of making a lateral anastomosis between the ileum and sigmoid. A valve-like opening is then made in the cæcum, into which a rubber catheter is placed, and the wound is sewn up, leaving the catheter in the cæcum, as in the case of a gastrostomy; by this means the colon is given complete rest and thorough irrigation of the large bowel may be performed. The result of this operation has not been satisfactory except temporarily; and on fully considering the nature of the disease a complete cure could hardly be expected; for the mucous secretion takes place as a result of a secretory neurosis and not from any local affection of the colon, and therefore any treatment which is directed towards giving the large bowel complete rest will not only not cure the disease but will be more likely to predispose the patient to a similar attack; moreover, the mental effect on the patient cannot be very beneficial, and the nutrition of the patient must also suffer very materially from cutting out so large an absorbing surface from the alimentary tract.

The second operation, which is being tried, is more simple in nature and consists in opening the abdomen and bringing the appendix to the surface and suturing it in position. Having secured it the distal end is removed, and so the appendix is made to take the place of the indiarubber catheter of the first operation. In this operation the colon is not given complete rest as no anastomosis is made with the sigmoid. The results from this operation ought to be more satisfactory than in the former case, because the functions of the colon are not interfered with and irrigation of the large intestine can be carried out very fully. Unfortunately the results of this operation are not known yet as it has only recently been undertaken; but even if is secures a more rapid disappearance of the symptoms during an attack the result will not be permanent unless the further treatment of the patient is correctly carried out; and this treatment must be directed towards securing a daily action of the bowels, combating the peculiar nervous condition present, and to removing any obvious organic disease which might have a deleterious effect by reflexly inducing the neurosis.

In the first place a suitable diet must be recommended and about this the opinions of the various authors of papers on the subject are diametrically opposed; for example, von Noorden [28] recommends a diet consisting of indigestible materials which leave a large residue, and he says "that the change from the patient's ordinary diet should be made suddenly, for then the unpleasant consequences are not nearly so lasting; but the nausea, sense of fulness, rolling noises, occasional pain and dyspepsia pass off in from two to four days: whereas, if the change from a light diet to a very indigestible one is made gradually the unpleasant symptoms remain for a much longer period." Langenhagen,[29] on the other hand, says: "The diet is to be carefully regulated, so as to avoid all indigestible material or such as could possibly produce fermentation." This latter form of diet certainly appears to be more in accordance with the views already expressed in this thesis; for giving a carefully selected diet of highly nourishing substances must be the best means of improving the patient's nutrition and so of improving the neurasthenia or other disease of the nervous system. A daily evacuation of the bowels is indispensable; and to attain this object full use of aperients must be made; and the particular one which has produced the best results in my hands is certainly castor oil, given in half-ounce doses daily, in the early morning and continued for weeks, or months, or even after apparent recovery has taken place. If castor oil cannot be tolerated one of the other aperients must be tried, such as cascara sagrada, calomel, or the saline aperients, &c. Occasional use of the enema is also of great assistance. Abdominal massage is certainly beneficial and should be performed for half an hour daily until the action of the bowels becomes regular. High-frequency currents have been recommended and a few of Hale White's patients derived some benefit, but in the majority no satisfactory result has been obtained from their application. Intestinal antiseptics are worse than useless.

With regard to the treatment of the nervous symptoms hydrotherapy and general massage are most useful, and patients are best treated away from home where they can secure greater freedom from business or social worries. If it is found impossible to treat both the nervous condition and at the same time to give proper attention to securing a daily action of the bowels every effort must be made to empty the large intestine, and doing this will so improve the general condition of the patient that in the majority of cases there will be an improvement in the nervous condition as well. If the disease is associated with any organic trouble, such as appendicitis, moveable kidney, &c., these conditions should receive the appropriate treatment, operative if necessary, and if general enteroptosis exists an abdominal belt should be worn.

CASES.

CASE 1.—The patient was a married woman, aged 54 years. At the age of 21½ years she had acute rheumatism. 21 years ago she miscarried at ten weeks. The cervix was much torn in removing the placenta after five days and the uterus prolapsed with much bleeding from a tear in the cervix. 20 years ago she had a right femoral hernia. 15 years ago she suffered from dull throbbing pains all over the abdomen constantly, with paroxysms of colicky pain preceding the passage of mucus which was first passed at this date. The mucus was passed in casts regularly for years at Easter, August, and Christmas—i e., during her children's holidays Intestinal sand was first passed 12 years ago. It was red in colour and variable in quantity; she had only passed sand three times. 12 years ago she alleged that she had peritonitis. She had had a moveable right kidney for eight years. She had passed two large gall-stones, the first eight years ago and the second one and a half years ago; it measured one inch long and three-quarters of an inch in thickness, and was accompanied by blood. She had been subject to fainting attacks for years, with feelings of cold and numbness all over, which passed off, and she sweated afterwards. She never lost consciousness. Occasionally before defæcation she had violent attacks of palpitation of the heart accompanied by great pain in the chest. There had been much improvement since oleum ricini had been administered freely and irrigation of the bowel had been performed. She still had attacks of colicky pain accompanied by the passage of mucus at intervals

CASE 2—The patient was a married woman, aged 62 years. She had always been neurotic and constipated. 12 years ago she had much abdominal pain, colicky in nature followed by the passage of scybala and mucus. The mucus was in long casts and shreds intermingled with fæcal material and a little blood There was much tenderness along the course of the colon, especially over the sigmoid flexure, in which hard fæces could be felt General enteroptosis was present and she suffered with hæmorrhoids With regard to her present condition interests of his younger colleagues, furthering their progress, guarding their rights, giving them every opportunity for their advancement, and rejoicing in their success. As one who had the happiness of working with Mr. Holmes for many years both at the Hospital for Sick Children, at St. George's Hospital, and in many other capacities, the writer would say most emphatically that it would be impossible to imagine a more loyal, kind, or generous colleague. His presence at the formal consultations held in the hospital theatre was of the greatest value, his large experience and wonderful memory enabling him to quote with unfailing accuracy whatever was available to throw light upon an obscure or difficult case and to correct (perhaps with gentle and good-natured irony) the errors which some of us may have been in danger of exhibiting. And yet he was always ready to listen to others and to act on their advice. In the medical school, too, he guided us with mature wisdom based upon a liberal outlook; he placed before us with the utmost clearness and impartiality the essentials of a discussion; and would take unlimited pains to surmount a difficulty. At the hospital board his judicial and well-considered advice, communicated in clear and admirably chosen words, always carried great weight with the governors. And then, besides his eminence in literature and science, his extensive reading, his fine scholarship, and his familiarity with modern languages made him a most delightful companion, whose genial and brilliant conversation was a welcome addition to any social gathering." It has fallen to the lot of few surgeons to be enshrined in the hearts of so many followers with respect as well as with affection, and a practical expression of these feelings by St. George's Hospital men may be seen in the admirable portrait of Holmes from Sir William Richmond's brush which hangs in the board-room of the hospital.

---

[28] Von Noorden: Op. cit.
[29] Langenhagen: Op. cit.

Holmes's private life was the quiet and cultured one that might be expected from one who was absorbed in a scientific career and its altruistic developments. He married a lady who was able to be his companion in his intellectual pursuits, Sarah Brooksbank, and to his widow who survives him we tender our respectful sympathy. She has the consolation of knowing that her husband's death will bring a sense of personal loss to hundreds whose names she has never heard.

Our portrait is a reproduction from a photograph taken at the date of Mr. Holmes's retirement from active membership of the staff of the hospital—i e., some time in 1888, when he was 63 years of age.

ANDREW GRAY, M.D. EDIN.

THE death of Dr. Andrew Gray of St. Helens occurred on August 30th as the result of a cycling accident. Dr. Gray was cycling in the town on August 24th and when passing a tramcar he collided with another cyclist and was thrown with great violence against the kerbstone of the footpath. He was carried to an adjoining surgery in an unconscious state and was afterwards found to be suffering from cerebral hæmorrhage. Despite surgical treatment he succumbed to his injuries on the 30th at the age of 43 years. Dr. Gray received his medical education at the University of Edinburgh, where he graduated as M.A. in 1884 and as M.D. in 1891. He was also a D.P.H. of the Victoria University. He leaves a widow and four children to mourn his untimely end. The funeral, which was largely attended, took place on Sept. 2nd at St. Helens cemetery. Military honours were accorded to the remains, as the late Dr. Gray held the rank of captain and honorary major in the 2nd V.B. South Lancashire Regiment.

CHARLES EDWARD KILKELLY, M.B. DUB., F.R.C.S. IREL., J.P.,

DEPUTY SURGEON-GENERAL, I.M.S.

Deputy Surgeon-General Charles Edward Kilkelly, who died on July 26th at his Dublin residence, 12, Upper Fitzwilliam-street, saw much active service in India during the Mutiny in 1857, and was one of the survivors of that conflict who were invited to attend a levée held by the King at Buckingham Palace in July of the present year. He studied medicine at Trinity College, Dublin, where he graduated as M B. in 1854, being also admitted F.R.C.S. Irel. in 1855. He received an appointment as surgeon in the East India Company's service in 1856, and was at Delhi on the outbreak of the Mutiny in May, 1857. Narrowly escaping from the massacre of Europeans in that city, he was afterwards attached to Lord Clyde's force which relieved Lucknow. On his retirement from the Indian Medical Service he returned to Ireland, residing sometimes in Dublin but more often at Drimcong, Moycullen, in County Galway, of which county he was a magistrate. The deceased was in his seventy-seventh year. In 1859 he married a daughter of Commissary-General Sir Randolph Routh, and leaves issue. The funeral, which took place in Glasnevin cemetery, Dublin, on July 29th, was largely attended.

ROBERT SAMUELS ARCHER, M.D. DUB.

THE news of the death of Dr. R. S. Archer of St. Domingo Grove, Liverpool, on August 8th in the fifty-eighth year of his age was received by the deceased's numerous friends with great regret. He had been in failing health for some time but the end came with remarkable suddenness. Dr. Archer received his medical education at Trinity College, Dublin, where he graduated B.A. in 1870, M.Ch. and M.B. in 1872, and M.D. in 1887. He was for many years physician to the Liverpool City Hospital at Priory-road, and for upwards of 16 years medical officer to the northern division of the Liverpool post-office. He was public vaccinator of one of the Everton districts and had a very large experience in the treatment of small-pox, of which he attended over 2000 cases in the epidemics in 1901–02. His evidence before the Royal Commission was the outcome of that experience and proved of great value. He frequently contributed papers to the medical press and one on the treatment of small-pox may be specially mentioned as being of wide import. He also contributed articles on vaccination, of which he had a very large experience. He was instrumental in organising the annual dinner of the Association of Dublin Graduates in Lancashire and Cheshire some years ago, was the honorary general secretary of the Liverpool Medical Institution in 1889, and was also a vice-president of that society. He leaves a widow and one son.

HENRY MURNEY, M.D. EDIN., M.R.C.S. ENG., J.P.

Dr. Henry Murney, who died suddenly from heart failure, at the advanced age of 82 years, at his residence, Tudor House, Holywood, co. Down, on August 25th, was little known to the present members of the medical profession in Belfast, but at one time he occupied a very prominent position. The deceased, who was a son of the late Henry Murney, J.P., of Belfast, studied in Edinburgh, London, and Dublin, and graduated M D. of Edinburgh about 1849, and he was also M.R C.S. Eng. Starting practice in Belfast he was demonstrator of anatomy under Dr. Hugh Carlisle, the first professor of anatomy in Queen's College, Belfast, and when the latter died Dr. Murney became a candidate for the chair, when Dr. Peter Redfern was appointed. In 1854 Dr. Murney was elected surgeon to the Belfast General Hospital (now the Royal Victoria Hospital), and for many years—up to 1886, when he resigned—he enjoyed an extensive surgical practice. He was president of the Ulster Medical Society in 1871–72. He was a well-known yachtsman and Freemason and a justice of the peace for Belfast and for county Antrim. Broad-minded and liberal in all his dealings he was held in high esteem by his professional brethren and by the public. His aged sister, with whom he lived (Dr. Murney was unmarried), died on August 25th and the news of her death so affected him that he passed away on the same afternoon.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Eduard Hitzig, who retired from the chair of psychiatry in the University of Halle about 14 years ago, since which time he has been living in retirement. His student days were passed in Berlin and Würzburg. After taking his doctor's degree in 1862 he practised in Berlin until his appointment as professor of mental diseases in Zürich in 1875. He only remained there for about four years, being then offered the chair of psychiatry in the University of Halle, together with the directorate of the lunatic asylum in Nietleben. He immediately set about establishing a university clinic for mental and nervous disease, this being the first clinic of the kind in any Prussian university. After a time a special building was erected for it in accordance with Professor Hitzig's own designs. His researches on the physiology and pathology of the brain are and over both ovaries. The pulsations of the aorta could easily be felt. The spleen was a little enlarged. She did very well under treatment with oleum ricini and occasional enemata of soap and water, and on her discharge from the hospital the constipation was relieved, there was no pain, and the stools did not contain any mucus.

CASE 17.—The patient was a single woman, aged 38 years. At the age of six years she had measles, which was followed by deafness and a discharge from her left nostril which still continued. When she was a child she had a great many abscesses on her neck, arm, and leg. At the age of 18 years the abscesses ceased to make their appearance and at this time she had attacks of bleeding from the rectum which sometimes continued for four or five weeks. She was not anæmic; she suffered from nose bleeding until she was 21 years of age. The catamenia were not regular but were often profuse. She had an operation performed for this condition. At the age of 23 years she had attacks of nervous prostration and lost the use of her limbs and voice for a time. At the age of 25 years she had slight intestinal obstruction. She had always bled very much after having teeth extracted. She had two sisters and one brother who suffered with bleeding from the rectum. She had always been very neurotic, suffering very much with flushing of the face followed by coldness. She had always had indigestion and said that the stomach felt like a stone and her face was very red. She had constipation and pain before the hæmorrhage started and diarrhœa afterwards. Her illness began after the attack of intestinal obstruction, at the age of 25 years, with cough, and pain in the left lumbar region which felt like sharp needles. The pains were also felt in the left iliac region and down the left leg, and they always preceded the hæmorrhage from the bowel. She suffered greatly with thirst. The stools on her admission to the London Hospital contained membranous shreds of yellowish colour which were of mucoid consistence and were four inches in length. There was no blood in the stools. An examination of the abdomen revealed nothing except tenderness all over the left side on palpation. On her discharge from the hospital she was much relieved. The treatment consisted of aperient medicines, and later salol was tried but this was changed and a pill was given containing cupri sulph., gr. ½, and opii, gr. ¼. Later oleum ricini was given daily, and saline injections, one drachm to the pint, twice a day.

CASE 18.—The patient was a man, aged 42 years. He had always suffered with indigestion. Six years ago he had inflammation of the bowels. He was quite well until a week before admission to the hospital; he then felt sick and had abdominal pains, chiefly in the hypogastric region. The bowels acted regularly until the attack began and then he suffered with diarrhœa. The stools contained a considerable quantity of mucus and a little blood. An examination revealed tenderness over the whole abdomen but especially marked in the hypogastric area. The tongue was pale and furred. He got well with treatment, which consisted of oleum ricini followed by bismuth carbonate and later by saline aperients.

CASE 19.—The patient was a man, aged 62 years. He had been all over the world and had dysentery 20 years ago. He had not had any other illnesses. The illness began four or five years ago. He suffered alternately with diarrhœa and constipation and had lost three stones in weight during the last five years. He had nausea when the diarrhœa commenced, and when he was constipated the stomach got very large and he suffered from flatulence. He had sharp pains in the stomach preceding the act of defæcation, and the pains were relieved afterwards. The stools contained a little blood and much mucus. On examination there was tenderness in the left iliac fossa. The liver was palpable and the dulness extended to near the umbilicus. There was a certain amount of gurgling in the lower abdominal region. He improved under treatment which consisted of aperient and antispasmodic medicines.

CASE 20.—The patient was a female, aged 30 years. She had not been well for the past ten years. She had had dysentery in South Africa four years ago. She had been ill for 16 weeks with pains in the abdomen which came on in very severe attacks. The bowels were always constipated and the stools contained much mucus which was of the consistence of jelly. She also suffered from neurasthenia. She was greatly relieved on her discharge from the hospital. The treatment consisted of oleum ricini, warm fomentations every four hours to the abdomen, enemata of olive oil, six ounces every night, enemata of soda one drachm to the pint every morning, and general massage for half an hour daily, followed by pilula Blaud with cascara.

CASE 21.—The patient was a single woman, aged 34 years. The first attack occurred six years ago and she had not been well since except during the intervals between the attacks. The intervals were about three months in duration. The bowels were always constipated. As soon as she began work again or took any solid food the attacks came on. She was taken ill in the night with intense pain in the stomach which caused her to faint. There was much retching and she vomited. The pain was of two kinds—a constant pain, felt chiefly in the upper and left part of the abdomen, which had lately increased in severity; and an acute smarting and stabbing pain, which came on ten minutes after food, which was felt chiefly in the epigastrium, and in about two hours time in the lower part of the abdomen. She had piles which bled and she had suffered with frontal and temporal headaches. When she took aperients a dragging pain was felt in the region of the sigmoid. The stools on admission to the London Hospital contained large constipated masses and much mucus. On examination, at one time nothing abnormal was felt in the abdomen, and subsequently there were a gurgling distension in the ascending colon and spasm in the sigmoid. The tongue was moist and the teeth were false. She did well under treatment which consisted of aperient medicines, hot fomentations to the abdomen, and soap and water enemata daily.

CASE 22.—The patient was a single woman, aged 32 years. She had been ill as long as she could remember, suffering with dyspepsia and a poor appetite. The bowels acted regularly as a rule. Two months before her admission to the London Hospital she suffered with pains in the stomach, which were sometimes dull and aching in character, and at times they were very sharp, "doubling her up," and when the acute pain was over she sweated and felt as if she had been beaten. The pains were sometimes brought on by even a very little food. She did not vomit but suffered from nausea. The stools contained very much thick, tough, gelatinous mucus but no membranes. On examination there was some deep tenderness in the epigastric region; the stomach was not dilated. There was a sensation of gurgling in the right iliac fossa with spastic distension of the colon. This was also noticed to a less extent over the sigmoid. She did well under treatment with aperient medicines and hot fomentations to the abdomen.

CASE 23.—The patient was a single man, aged 30 years. He was a strongly built athletic man accustomed to the usual games. He was decidedly of a nervous temperament, and frequently had flushings of the face and a slight catch in the voice. He had had constant attacks of diarrhœa accompanied by the passage of slime in the stools. Eleven years ago he was seen by Sir Frederick Treves who said that he had appendicitis and he was advised to have appendicectomy performed when the attack had subsided. The attack lasted ten days and as he felt quite well afterwards he refused operation, but very soon the attacks of pain, diarrhœa, and passage of slime came on at intervals of some months at first but lately every week. The attacks of diarrhœa came on more frequently (as many as 15 stools being passed in a day). The attacks were accompanied by pain and slight tenesmus. The pain was chiefly felt in the right iliac fossa but also in the left when the attacks were on. The attacks always came on when he was at work in London but not on a holiday. The stools contained a large quantity of mucus but no definite casts were passed while he was under observation. The bowels were constipated between the attacks. On examination the abdomen moved normally. There was distinct tenderness in the right iliac fossa. The right rectus was more rigid than the left at the lower part. To the outer side of the right rectus muscle an indefinite mass could be felt which was distinctly tender on palpation. He was operated on on Oct. 18th, 1906. The appendix was found in a mass of adhesions, the distal end being represented by a fibrous mass. The appendix was removed. Convalescence was uninterrupted and he has remained free from the attacks ever since.

CASE 24.—The patient was a married woman, aged 31 years. She had been ill ever since her first child was born seven and a half years ago. She got worse with each, successive pregnancy. She had had anæmia, gastric ulcer with hæmatemesis, pains in the stomach, &c., and had always been constipated. She was in bed for four months last year with a miscarriage and an offensive vaginal discharge. She was markedly neurotic and constipated and suffered from abdominal pains which preceded defæcation. The stools on admission to the London Hospital contained much granular débris and mucous casts. On examination the tongue was tremulous and furred. There was slight oral sepsis, and tenderness on palpation was noticed over the lower descending colon. The stomach was not dilated. The kidneys and liver were not palpable. Later there was tenderness over the ascending colon and sigmoid. A sigmoidoscopic examination showed nothing abnormal except slight superficial erosions. She was treated with aperients, enemata of soap and water, and olive oil, and turpentine stupes were applied to the abdomen. As her condition on her discharge from the hospital was not satisfactory she was advised to have an operation performed (appendicostomy).

CASE 25.—The patient was a single woman, aged 30 years. She had suffered for years with pains in the stomach after food and with dysmenorrhœa. She was markedly neurotic. She had been ill for two years. She had suffered much from constipation and abdominal pains, which were felt chiefly in the sides of the abdomen and were "bearing down" in character and were felt both before and after defæcation. The stools contained scybala, mucus, and a little blood. On examination the tongue was moist and coated. The stomach was not dilated. The sigmoid was loaded with hard fæces and there was gurgling in both iliac fossæ. She improved greatly under treatment with aperient medicines and enemata of soap and water every morning.

St. Neots.

NOTES ON, AND REMARKS SUGGESTED BY, A CASE OF MALIGNANT ENDOCARDITIS (DIPHTHERITIC) WITH TERMINAL CEREBRO-SPINAL SYMPTOMS.

BY J. T. C. NASH, M.D. EDIN., D.P.H. CANTAB.,
MEDICAL OFFICER OF HEALTH OF SOUTHEND-ON-SEA; MEDICAL SUPERINTENDENT OF THE BOROUGH HOSPITAL FOR INFECTIOUS DISEASES, ETC.

THE following experience which I believe to be very rare justifies a few remarks on this subject.

On March 14th, 1907, I was informed that a male child, aged between three and four years, had died suddenly during the night, having the previous day exhibited marked retraction of the head, strabismus, and other signs of cerebro-spinal meningitis, including a copious petechial rash all over the body. I suggested a *post-mortem* examination and this was arranged for and carried out on the 16th, the attending medical man and myself being present. The boy had been medically attended for about a week on account of headache, loss of appetite, furred tongue, constipation, and a fugitive erythematous rash, the provisional diagnosis being "gastric disturbance." The later symptoms of occasional delirium, restlessness, and tenderness along the back, with a continuance of drowsiness, headache, and fever, had suggested the possibility of malignant endocarditis, but the stethoscope failed to find any clinical evidence of valvular defects though carefully searched for on the day before the child's death. Slight jaundice was observed two days before death; retraction of the head and strabismus about 36 hours before death; and the petechial rash and slight opisthotonos only on the last day of existence.

At the *post-mortem* examination we observed a copious petechial eruption of the skin of wide distribution. There

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BERRY, JOSEPH FOREMAN, M.B., Ch.B. St. And., L.R.C.P. & S. Edin., has been appointed Assistant Medical Officer of Health of the County Borough of Wigan.

BINGHAM, R. G., M.R.C.S., L.R.C.P., has received a Resident Appointment in the Throat Department at St. Thomas's Hospital.

BRISTOW, W. R., M.R.C.S., L.R.C.P., has been appointed a House Surgeon to Out-Patients at St. Thomas's Hospital.

BURGESS, A. S., M.R.C.S., L.R.C.P., *has been appointed* Senior Ophthalmic House Surgeon at St. Thomas's Hospital.

CARLETON, H. H., M.B., B.Ch. Oxon., has been appointed a House Surgeon to Out-Patients at St. Thomas's Hospital.

COOKE, A. I., B.C. Cantab., has been appointed Junior Ophthalmic House Surgeon at St. Thomas's Hospital.

DAWES, H. E. T., M.R.C.S., L.R.C.P., has been appointed a House Surgeon to Out-Patients at St. Thomas's Hospital.

DRAKE, A. W. C., M.R.C.S., L.R.C.P., has received a Resident Appointment in the Throat Department at St. Thomas's Hospital.

HEWETT, F. S., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

HUGGINS, G. M., M.R.C.S., L.R.C.P., has been appointed a Resident House Surgeon at St. Thomas's Hospital.

JACK, W. A. MORTON, M.R.C.S., L.R.C.P., has received a Resident Appointment in the Children's Surgical Department at St. Thomas's Hospital.

MCWALTER, J. C., M.D. Brux., M.A., F.F.P.S. Glasg., D.P.H., Barrister-at-law, has been appointed Examiner in Medical Jurisprudence to the Apothecaries' Hall of Ireland.

finding lodgment on the valves. Here they produced vegetations some of which by embolism were carried to the various organs affected, including the brain and spinal cord. Such distribution of the diphtheria bacillus is thought to be extremely rare. Indeed, *malignant* endocarditis is an extremely rare complication of any of the usual infective fevers. Cerebro-spinal symptoms in association with malignant endocarditis have been observed, of course, but I am not aware that the diphtheria bacillus has been demonstrated as the infecting organism in any recorded case previous to the present communication. If any such cases have been recorded previously the rarity of the condition appears to me to justify the present record.

Southend.

A CASE OF DOUBLE OPTIC NEURITIS; SYMPTOMS OF CEREBELLAR TUMOUR; COMPLETE RECOVERY.

BY CHARLES HIGGENS, F.R.C.S. ENG.

A BOY, aged six years, was brought to see me on May 22nd, 1894. I was told that it had been accidentally discovered that he could not see properly and that six weeks before his sight appeared to be perfect. He could distinguish none of the test types. In his right eye the optic disc was swollen and its outline was blurred. The left disc was red but its outline was well defined and it was not swollen. He had some nervous symptoms resembling chorea; there was no albumin in the urine. I advised that he should consult a physician and did not see him again at that time. Two years later, on June 9th, 1896, I saw the patient's mother, who told me that he became quite blind but began to recover slowly and eventually got quite well. On Sept. 19th, 1904, I saw him again. He was myopic and I thought that his discs were rather pale. His vision was:—

Right eye $\frac{6}{36}$ c − $\frac{75 \text{ cyl.}}{2 \text{ sph.}}$ $\frac{6}{6}$; left eye $\frac{6}{36}$ c − $\frac{75 \text{ cyl.}}{1{\cdot}60 \text{ sph.}}$ $\frac{6}{6}$.

I saw him again on May 6th, 1907. He was a tall well-set-up fellow of 19 years and appeared to be perfectly healthy. His discs were rather pale; his myopia had increased by 1 D. but his vision was $\frac{6}{6}$ with correcting glasses and both fields were normal. He told me that after I saw him in 1894 he was taken to Dr. Ferrier. I wrote to Dr. Ferrier and asked him if he would look up his notes of the case and let me know what he made of it, and he very kindly wrote to me as follows: "I first saw the boy in May, 1894; he then had double optic neuritis, more marked in the right eye, and some symptoms of cerebellar disease. In July of that year the cerebellar symptoms were marked, but the neuritis had disappeared and the discs were somewhat pale. He could only read J. 20. In March, 1895, his vision was $\frac{6}{12}$. He appeared otherwise well. My diagnosis was cerebellar tumour? Might it be a tubercular nodule which has become cretified?"

Remarks.—*The duration of the boy's illness appears to* have been under 12 months; as far as was known he was quite well six weeks before he saw me in May, 1894, and from Dr. Ferrier's report he had quite recovered by March, 1895; his vision being *only* $\frac{6}{12}$ was probably accounted for by a low degree of myopia.

The case is interesting chiefly on account of the complete recovery which took place; my experience of similar ones is that they almost invariably go blind and that some of them die, though often years after the appearance of the first symptoms. The patients wander about from hospital to hospital, or from one medical man to another, blind and staggering, and it is rare for the surgeon or physician who first sees them to see the end of them. I have been in the habit of pointing out blind staggering children and calling them cerebellar children, and in one or two cases in which I have seen a necropsy tumour in the cerebellum was found. In the case reported Dr. Ferrier's suggestion that it might be a tuberculous nodule which has become cretified is probably correct, but there is the possibility of congenital syphilis, though the patient shows no signs of it and I have not gone into the history.

Treatment, so far as I know, does no good, but one has to do something and if a case recovers under any kind of treatment so much the better. I have trusted mainly to mercury and iodide and in two cases have trephined with very marked relief, which was, however, only temporary, and the last time I saw the patients they appeared to be neither better nor worse for the operation.

Brook-street, W.

A CASE OF LAND SCURVY

OCCURRING IN A PATIENT AFTER A PROLONGED PERIOD AS AN IN-PATIENT IN A HOSPITAL AND AS A COMPLICATION OF A FISTULA IN ANO.

BY J. BERNARD DAWSON, M.B., B.S. LOND., M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, CITY ROAD, LONDON, E.C.

WHAT is the determining factor in the *etiology of scurvy* as yet remains a problem of medical science. Whether the theory of chronic ptomaine poisoning or whether that of dietetic error be the truth is undecided by those who have studied the subject especially, evidence seeming to be equally strong for both. Experimental information resolves itself into two classes, that resulting from laboratory work proper and that gleaned from the logbooks of Arctic and other expeditions. The experiments of Harley and Jackson consisted in the feeding of apes with scorbutic and antiscorbutic diets. Their results seem to be mitigated by the following facts: (1) that *monkeys are not naturally* carnivorous; (2) that the tinned meats used were allowed to become tainted after preservation and not before, as is the case of the doubtful canned food found in the cheapest shops or in marine stores; and (3) that the *digestive economy* of the lower primates seems to be capable of dealing with putrescent food.

Briefly, the evidence derived from the reports of travellers during the past six years is as follows. 1. Dr. Koettlitz, who accompanied both the Nansen and the British National Antarctic Expeditions, reports in reference to the latter that there was very considerable trouble from disablement of the crew from scurvy, notwithstanding the fact that limejuice occupied a prominent position in the rations served out daily. It was found out on investigation that the preserved meat supplied for the expedition was not beyond reproach. 2. The Jackson-Harmsworth Arctic Expedition yielded some interesting facts. When the relief ship reached them it was with the intention of getting back before the ice closed. In this they were unsuccessful and the vessel with her crew remained 12 months. The men who were encamped on the ice lived during this year, as they had for many months before, upon fresh bears' meat, taking no limejuice; they escaped any attacks of scurvy. Those who remained on the ship, refusing bears' flesh, chose to consume canned goods, often in an unwholesome condition, and notwithstanding the fact that a limejuice ration was served out daily, in the course of the year, all suffered and two died. 3. When Nansen and his companion Johansen left the *Fram* in their attempt to reach the Pole by sledge they were away 15 months, during which they existed entirely upon the flesh which fell to their skill as hunters and endured terrible hardship and toil, despite which they returned hale and whole.

In deducing from such statements as these it must be *borne in mind* that limejuice varies in quality and that the good intentions of the medical man in charge may have been rendered abortive by a sailor who disliked limejuice.

Such is the evidence of the ptomaine theory; evidence equally strong can be rallied upon the side of the dietetic supposition. 1. In 1795 Sir Gilbert Blane introduced a limejuice ration into the navy's diet-sheet, with the result that scurvy, which had been very prevalent, became comparatively rare. It was, however, pointed out by Aitken in 1872 that Blane at the same time greatly improved the food generally. 2. Lieutenant-Colonel Hamilton reports the following.[1] In 1885 he was in charge of the 23rd Pioneers, a Sepoy regiment, during an expedition among the hills of the northern *frontier of India.* Owing to the roguery of the native contractors the supply of vegetables arranged for failed. After a few weeks, in spite of the fact that fresh meat was abundant, scurvy showed itself among the troops. A small green cruciferous plant, found growing upon the hills, was then used as a spinach, with the result that rapidly the scurvy disappeared. 3. Dr. F. C. Sinclair in medical charge of a guano expedition to Walfisch Bay, S.W. Africa, states that his 400 Damara natives remained free from scurvy whilst the supply of freshly killed meat was good. His cattle, however, were carried off by rinderpest. The diet then consisted of peas, wheat meal, porridge, rice, bread, biscuits, tea, and coffee, all sound food. In two months scurvy was prevailing among the negroes,

Notes, Short Comments, and Answers to Correspondents.

THE USE OF COCAINE IN THE MORPHIA HABIT—A WARNING.

To the Editors of THE LANCET.

SIRS,—During the past six months I have had several morphia habitués under my care who, on the advice of medical men, have taken cocaine with a view to curing themselves of the morphia habit. It cannot be too widely recognised that it is not only useless, but in the highest degree dangerous, to prescribe cocaine in these cases; it is true that cocaine does to a certain extent neutralise the effect of morphia, but this, in point of fact, is a disadvantage rather than a gain, as it merely tempts the patient to take larger doses of morphia and then balance the excess with a heavy dose of cocaine.

But the principal danger lies in the fact that such treatment inevitably produces the cocaine habit, by the side of which the morphia habit is comparatively insignificant: uncomplicated chronic morphinism is usually curable, but when patients begin to take cocaine also the difficulties of the situation are increased a hundredfold. Not only is their immediate condition rendered worse by the advent of delusions and hallucinations but their chance of ultimate cure is very much lessened and relapses are much more common than in cases of simple morphinism.

The sudden withdrawal of cocaine leads to no actual distress or reflex disturbances such as occur in the case of morphia, and when these patients know this they are very apt to return to the cocaine, reassuring themselves meanwhile with the idea that they can break it off at any time without acute suffering. In a fairly large experience of morphia cases I have never seen a single cure expedited by the use of cocaine and its dangers are so great as to make its recommendation quite unjustifiable.

I am, Sirs, yours faithfully,

Harley-street, W., August, 1907. J. HENRY CHALDECOTT.

RAPID TRANSPORT IN THE EIGHTEENTH CENTURY.

To the Editors of THE LANCET.

SIRS,—It may interest your readers, those in the profession, to feel that with the motor-car they have what was longed for 150 years ago. Let me extract from "Tristram Shandy":—"Because," continued my uncle Toby, "the celebrated sailing chariot which belonged to Prince Maurice, and was of such wonderful contrivance and velocity as to carry half a dozen people 30 German miles in I don't know how few minutes, was invented by Stevinus, the great mathematician and engineer." ...... "But pray, Dr. Slop," quoth my father, "upon what principles' was this self-same chariot set a-going?" "Upon very pretty principles, to be sure," replied Dr. Slop, "and I have often wondered why none of our gentry, who live upon large plains like this of ours (especially they whose wives are not past child bearing) attempt nothing of this kind; for it would not only be infinitely expeditious upon sudden calls, to which the sex is subject—if the wind only served—but would be excellent good husbandry to make use of the winds, which cost nothing, and which eat nothing, rather than horses, which (the devil take 'em) both cost and eat a great deal." So we see that Laurence Sterne had prophetic ideas, like as where he writes that he would turn all people who from the country came with their wives and families to London back like vagrants to their legal settlements. Now we are overcrowded, and where and how will it end?

I am, Sirs, yours faithfully,

Woodford, Sept. 7th, 1907. EDWIN LITCHFIELD.

THE JAPANESE BATH.

ACCORDING to a well-written, and equally well-illustrated, paper in the *Journal of the Royal Army Medical Corps* for July by Major K. Bruce Barnett, entitled "Baths and Bathing in Japan," the Japanese, in their persons and houses, are the cleanest people in the world, and every man, woman, and child, of high or low degree, has a daily hot bath. The bathing habit is universal and dates back to the days of mythology, the baths being taken at a temperature which is perfectly astonishing to people who are only acquainted with the tepid water of Europe and America. There are many public baths in Japan, but nearly every private house has one, either in the house itself or adjacent to it. The ordinary bath consists of a large wooden tub, oval in shape, and fitted with a cover. At one end it is traversed by a copper tube in which charcoal can be made to burn, the water in this way being readily raised to the required temperature. Before he enters the tub the bather thoroughly lathers himself from head to foot and washes the suds off by means of a wooden ladle or dipper. He then sits in the tub immersed up to his chin for several minutes, enduring a degree of heat by which a European would be well-nigh parboiled. When first Japan began to study the methods of Western nations the excessive heat of the baths was strongly condemned and a [illegible] hat the water in the public baths should be only moderately heated. This caused great discontent, so a committee composed of European and Japanese medical men was appointed to decide the question. The verdict was in favour of the national custom which was pronounced to be not only harmless but beneficial. The high temperature of the water was said to open the pores of the skin thoroughly, even without the use of soap; and a healthy action of the skin and cleanliness were secured which it was impossible to get with any amount of washing in cold or so-called hot baths. The hotter the water the less chance there was of catching cold, while a very hot bath taken when it was felt that a cold was coming on was the very best method of aborting it. The invigorating effect of a very hot bath after a tedious day's journey in hot or cold weather was wonderful, and very different from the relaxing effect of a tepid bath. It soothed the nerves, eased the tired muscles, promoted appetite, and gave sound sleep. In very cold weather a really hot bath had the effect of preventing the cold being felt for several hours afterwards, while in hot weather it had a distinctly cooling effect.

A SUGGESTED MEDICAL BADGE.

To the Editors of THE LANCET.

SIRS,—The following incident has impressed upon me the desirability of the members of our profession wearing a distinctive badge or other emblem by which we could be recognised as followers of the healing art.

At a political gathering at which I happened to be present the other day one of the audience was seized by a fainting fit. Some of the people on the platform signalled to me that my services were required and I was soon by the side of the sufferer. I removed him away from the crowd, unloosened his clothes, and laid him down on the ground. Just as he was beginning to come round a gentleman whom I did not know, evidently also a doctor, made his way to the spot where I was kneeling with my fingers on the pulse of the patient, and without taking the least notice of me commenced to busy himself with a hypodermic syringe case. As the patient was getting better I said to the newcomer that an injection was not necessary, whereupon he brusquely answered me, "You mind your own business." I merely retorted, "Well, it is my business, since I am a doctor and was here before you." This brought an immediate apology from my colleague, who, looking at me more closely, recognised me as a former fellow student of his. We both took the situation calmly and there was no further unpleasantness, the patient meanwhile continuing to improve. But the group of people standing round enjoyed the discomfiture of my friend who made a hasty retreat, so that altogether the scene was one that brought no credit to our profession.

Now I am far from blaming my friend. He did not know that I was also a doctor and was probably nettled at being interfered with by one whom he took to be a layman. But had I in the place of, or in addition to, my conventional silk hat and frock-coat worn a badge or mark such as I suggest the incident would not have occurred. On former occasions when happening to be near an accident and willing to render what aid I could I have had to fight my way through the crowd and to exclaim: "Let me pass, I am a doctor." Once a policeman would not believe me when I offered my services in such circumstances, probably because I wore a lounge jacket and soft hat.

I should imagine this must be a common experience of most medical men and therefore throw out the suggestion that in the absence of a special garb to which there appears to be an objection which I do not share, we should all provide ourselves with a distinctive badge or rosette to be worn regularly or exhibited when the occasion demands it. If there is already such a badge in existence anywhere it would be a great advantage to introduce it universally, on the analogy of the Esperantist badge. I can conceive numerous situations when such a means of mutual recognition would be of the greatest benefit and trust that the matter will be taken up by the medical press of this and other countries.

I am, Sirs, yours faithfully,

Manchester, Sept. 9th, 1907. J. DULBERG.

CEMENTS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers recommend to me, for the mending of glass measures, a cement that will stand the subsequent wetting of every-day use? I have tried most of the ordinary advertised cements, but none will stand frequent wetting even with cold water. I have seen a cement which set in a few minutes like marble and would stand soaking in hot water. The user of it, a serpentine worker in Cornwall, told me that it was simply plaster of Paris with powdered rosin. I have tried every combination of these two without any success. I have also tried a prescription for plaster of Paris with a solution of rosin in caustic soda, but with equal lack of success. There are so many small breakages of glass vessels in a surgery that a cement such as I have indicated is a great desideratum.

I am, Sirs, yours faithfully,

Bromsgrove, Sept. 10th, 1907. C. KIDD.

*** We shall be glad to hear from any of our readers who may have had experience of a cement such as our correspondent requires. In the meantime we would recommend him to try one of the two following: 1. Freshly burned quicklime and casein. The most convenient form of casein is the soluble form known as casumen, which may be obtained from Messrs. Pridcaux, of Motcombe, Dorset. Mix the casein with water into a fairly thick cream. Then gradually add the quicklime, which must be freshly burned and in fine powder. Stir all the time until the mixture, which will become hot, gets sticky.

had been dead at least 48 hours, and post-mortem changes had taken place, but was not considered to have suffered from "grouse disease"—i e., the form of epidemic disease described by Professor Klein in the grouse. No fresh blood films were examined but only dry films stained either with Leishman's or Giemsa's stain.

The protozoal organisms found were fully grown and sexually differentiated sporonts of a leucocytozoon. They were fairly abundant but in a state of degeneration and stained badly. The following is a brief provisional description: Macrogametes of an oval shape, more or less elongate, 19 μ to 25 μ in length by 12 μ to 16 μ in width. The cytoplasm has a coarse alveolar structure, stains intensely blue, and usually presents one or more clear spaces or vacuoles. Nucleus either rounded or oval and placed as a rule about the middle of the parasite. It stains very faintly and contains as a rule near the periphery a compact, deeply staining chromatin mass. Microgamatocytes slightly smaller than the female sporonts, with hyaline cytoplasm which stains very faintly or not at all and rarely contains vacuoles The nucleus is considerably larger than in the macrogamete.

The parasites are contained in oval or spindle-shaped elements with the extremities usually drawn-out into fine long threads not unlike flagella. The nature of these elements is not quite clear; they appear to be blood cells greatly altered by the parasites they inclose. They present a deeply stained nucleus pushed to one side and flattened by the parasite which entirely occupies the short diameter of its host-cell; at either extremity are numerous chromatoid granules. This leucocytozoon of the red grouse appears to differ from the leucocytozoa parasitic on the turkey and guinea-fowl described by Laveran and Lucet and by Neave respectively, and since we consider it to be a hitherto undescribed species we propose to call it *Leucocytozoon lovati* after Lord Lovat, chairman of the Commission upon Grouse Disease.

THE CLINICAL SIGNIFICANCE OF ALLOCHIRIA.[1]

BY ERNEST JONES, M.D. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE LONDON SCHOOL OF CLINICAL MEDICINE, DREADNOUGHT SEAMEN'S HOSPITAL.

DURING the past two years I have had the opportunity of making a detailed investigation of some cases of allochiria, a complete study of which will shortly be published, together with a full discussion of the pathogenesis of the condition. The fact that this paper is therefore merely a preliminary communication containing a summary of the results of the above study is advanced as an explanation of any appearance of dogmatism in the remarks that follow. Only the clinical significance of the condition will be considered, as the subject of pathogenesis would need a lengthy exposition.

In spite of Professor Janet's remarkable essay, which has not yet received the attention it deserves, it may be said that the views held on the subject by most neurologists can be summarised in the following statement, which is taken from the most complete modern text-book we have—namely, Nothnagel's "Specielle Pathologie und Therapie". "Allochiria is a defect in localisation, whereby a patient refers a cutaneous stimulus to the corresponding contralateral point; it occurs in a large number of diseases, notably tabes and hysteria, and is of no value in diagnosis." How inexact is this account of the condition will be seen presently.

The symptom first described by Obersteiner under the name of Allochiria refers to two entirely different conditions which hitherto have not been differentiated from each other by any writer. The one, which may be called "false allochiria," is an instance of the localisation defect known as alloæsthesia. The other, for which I have proposed the designation "Dyschiria" or "Dyschirognosis," is an instance of psychological disaggregation, and comprises three distinct varieties, of which true allochiria is one. In addition to these the terms "electromotor allochiria" and "reflex allochiria" have been applied by Weiss to conditions in which a unilateral stimulus evokes either a bilateral or contralateral motor response. There is no reason whatever why the term "allochiria" should be used in this connexion and I shall not mention the conditions further. One might just as soon call the consensual reaction of the pupil to light allochiria, particularly if the direct response is abolished, as happens in lesions of one third nerve.

I shall first give a brief description of false and true allochiria with their distinguishing characteristics and shall then consider their clinical significance. In alloæsthesia there is erroneous localisation of cutaneous stimuli, which are referred by the patient to points more or less distant.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch" should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An Address

ON

THE OPERATION OF GASTRO-JEJUNOSTOMY AND ITS PHYSIOLOGICAL EFFECTS.

Delivered at the Annual Meeting of the American Medical Association at Atlantic City, U S.A., on June 5th, 1907,

By HERBERT J. PATERSON, M.A., M.B., B.C. Cantab., F.R C.S. Eng.,

ASSISTANT SURGEON, LONDON TEMPERANCE HOSPITAL; LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Mr. President and Gentlemen,—When your distinguished President of last year conveyed to me a cordial invitation to be present at this meeting of the American Medical Association I accepted at once, thinking of the opportunity which I should have of seeing for myself and profiting from the work of the many in your country whose fame has spread across the sea. When, however, I came to seek for a subject on which to address you I realised the rashness of my ready compliance. So much work has been done here on that branch of surgery in which I am especially interested that I felt that were I to dwell on any purely surgical aspect of gastric disease I should be going over ground already familiar to you and so should be trespassing too far on that indulgence and leniency which I have heard you so invariably extend to those who are your guests.

In my Hunterian lectures delivered before the Royal College of Surgeons of England last year I gave the results of some investigations into the effect of the operation of gastro-jejunostomy on the metabolism of the human body. After some consideration I determined to pursue those investigations further and to lay the results before this meeting. When, as was the case but a few years back, the operation of gastro-jejunostomy was performed only as a last resort in cases of pyloric stenosis, physiological questions were a secondary consideration, but at the present time when the operation is frequently advised for conditions such as intractable gastric ulcer, in which it is an operation of expediency rather than of necessity, a knowledge of its precise effects on the gastric and metabolic functions of the body must be one of the determining factors in the decision for or against operation. It is on this aspect of gastro-jejunostomy that I propose to offer some observations for your consideration to day.

I. The Effect of Gastro-jejunostomy on the Functions of the Stomach.

1. *The presence of bile in the stomach.*—All observers are agreed that a certain amount of bile finds its way into the stomach after the operation of gastro-jejunostomy. It is said that the quantity is at first fairly abundant but after a few weeks considerably less. In my own experience it is rare to find bile in the fasting stomach, and I regard its presence under such conditions as evidence of inefficiency of the efferent opening. The fluid drawn off one hour after a test breakfast often appears to contain bile, but Gmelin's test usually gives a negative result. If the gastric contents be tested two hours after a test meal Gmelin's test is frequently obtainable. I use the expression obtainable advisedly, for considerable care is often requisite to demonstrate the presence of bile, although from the appearance of the gastric contents one would judge that it is present in some quantity. Indeed, I believe that the amount of bile which regurgitates into the stomach is considerably over-estimated. Gmelin's test does not give a positive reaction unless bile be present to the extent of about 5 per cent. and the green colour of the test is, as a rule, only just visible, and sometimes cannot be seen at all. It is probable, therefore, that the regurgitated bile forms not more than 5 or 6 per cent. of the stomach contents. I need hardly point out that if bile gains entrance into the stomach pancreatic secretion must do so as well. Granted, then, that there is a permanent reflux of bile into the stomach after gastro-jejunostomy the question arises, Is its presence harmful? All the evidence indicates that it is not, provided the efferent opening of the anastomosis is efficient. Dastre and Massé have shown that in dogs the presence of bile in the stomach does not interfere with the digestion and general health. The well-known case reported by Moynihan as well as the results of the operation of cholecysto-gastrostomy in man confirm these observations, while the metabolism experiments to which I will refer later afford further evidence to the same effect. Indeed, I think we may safely affirm that in part at least the beneficial effects of gastro jejunostomy on gastric ulcer are due to the entrance of the alkaline pancreatic juice and bile into the stomach.

2. *The effect of gastro jejunostomy on the gastric secretion.*—The most marked effect of gastro jejunostomy is the diminution of the total acidity of the gastric contents which follows operation. At first sight it would appear that this diminution is but the result of partial neutralisation of the gastric contents by the bile and pancreatic juice which gain entrance into the stomach. But the problem is not such a simple one. The time at my disposal will not permit me to describe in detail the observations which I have made on this interesting subject, so I will briefly indicate what appear to me to be the chief factors at work. From an examination of a considerable number of cases I find that the average diminution of the total acidity after gastro-jejunostomy is about 35 per cent. There are several reasons which appear to me to indicate that this diminution is not due solely to partial neutralisation. First, judging by the amount of bile usually found in the stomach, the diminution is too great to be the result of a purely chemical reaction. Secondly, if the diminution were the result of a chemical reaction, we should expect all the free hydrochloric acid to be neutralised, but this is not invariably the case. In several cases I have found free hydrochloric acid present, and in those cases in which it has been present before operation it can usually be demonstrated after operation by giving a suitable test meal, such as Leube's. Thirdly, there is a diminution of the total chlorides in the gastric contents which must be the result, not of neutralisation, but of diminished secretion.

Two factors at least, therefore, appear to be at work in bringing about the diminution of total acidity which is found after gastro-jejunostomy: (1) a diminution of the total chlorides secreted; and (2) partial neutralisation of the gastric contents by bile and pancreatic juice. The brilliant researches of Pawlow and his co-workers have demonstrated the striking interdependence of the secretions of the digestive glands, and it is this interdependence which seems to me to afford us a reasonable explanation of the diminution of chlorides. We may, I think, safely assume that during the churning movements of the stomach some of the gastric juice will be, as it were, squeezed through the anastomotic opening. This escape of some of the acid will prevent the total acidity rising as high as would otherwise be the case. But it will have a further effect. The presence of an acid fluid in the jejunum causes a secretion of pancreatic juice (Wertheimer). Thus, after gastro-jejunostomy, if my hypothesis be correct, the early presence of acid in the jejunum will lead to a flow of pancreatic juice at an earlier period of digestion than in a normal individual. With this earlier stimulation of the pancreas there will be a correspondingly earlier diminution of the gastric secretion, and as a consequence of this, a diminution in the total chlorides secreted by the gastric mucous membrane. Possibly other factors are at work, such as an inhibitory effect of secretin or other constituent of the pancreatic juice, while in those cases in which there has been hyperacidity before operation the removal of the abnormal excitation of the gastric mucosa which results from spasmodic stenosis of the pylorus will lead to a considerable diminution of the total chlorides, and it is certainly significant that it is just in these cases of gastric ulcer with hyperacidity that the diminution of the total acidity of the gastric contents is most marked.

3. *The effect of gastro jejunostomy on gastric digestion.*—Some authorities maintain that gastric digestion is lost after gastro-jejunostomy. Even if this were true it is not of such importance as would at first sight appear, for we know from the experiments of Pachon and Carvalho on dogs, from the observations made on Schlatter's celebrated case of total gastrectomy, as well as from the clinical evidence afforded by those patients who have survived complete removal of the stomach, that Nature is able to dispense with this organ. There is, perhaps, nothing more wonderful in the whole range of surgery than that human beings should not only survive the operation of total gastrectomy but should remain for years in the enjoyment of perfect health and activity. I need hardly remind you that the first surgeon to

obviously a natural part of his own body and the corresponding sensation has no abnormal attributes.

Coming now to the question as to the value of these symptoms in diagnosis, let us first consider the false or alloæsthesic allochiria. This can be distinguished with certainty from true allochiria by means of the data given above. The only other matter I wish to refer to in this connexion is the fact that allochiria may be simulated by a peculiar irritable condition of the lowest afferent neuron system. In this hyper-excitable state, which is not very rare in tabes and in certain affections of the peripheral nerves, the patient experiences an indefinite number of hallucinatory sensations which he refers to various precise points on the surface of either limb. The condition is easily recognised by the fact that sensations are experienced independently of objective stimulation and are increased in vividness when the element of expectant attention is added, but, if the possibility of its presence is not borne in mind, it is equally easy for the condition to be mistaken for allochiria or at least for alloæsthesia. The clinical significance of this form of alloæsthesia is that of erroneous localisation in general so that I need not discuss it here. There is no doubt that the symptom is most marked in affections in which the articular excitations are impaired, and this is probably the reason why it is so often and so well seen in tabes.

The relation of dyschiria to diagnosis must be discussed from two points of view: first, the diagnosis of dyschiria; and secondly, the significance of dyschiria as regards diagnosis of the affection present. It is convenient to discuss separately the sensory and motor aspects of the former problem.

When it is observed that a cutaneous stimulus is referred to the opposite side it can readily be determined, as stated above, whether allochiria or alloæsthesia is present by a knowledge of the distinctive features of those conditions. The observation of the transference of sensation may not be made however and in this case the condition will be overlooked. Even when a patient's localising capacity is being tested it may not occur to the observer expressly to inquire as to the side on which the sensation is felt; this is especially likely in true allochiria when the patient localises every stimulus with exactitude and certainty. Further the allochiria may be present only in connexion with certain kinds of stimuli. The other two varieties of dyschiria are overlooked still more easily, especially as they are less known. In the achiric variety there is no transference of sensation and even if the patient is questioned as to its side he replies simply, "I don't know," so that the state of affairs will not be correctly interpreted unless the observer is aware of the existence of this variety of dyschiria. In the synchiric variety three sub-varieties occur, all with their special fallacies of observation. In the first and most advanced of these three the contralateral sensation is appreciated most distinctly, and if the patient mentions only this one the condition may be mistaken for allochiria, a serious prognostic error. In the second subvariety the sensations on both sides are appreciated with equal distinctness; the patient usually says that he was touched on both sides, but if he thinks only one touch has been applied he sometimes says he does not know which side was touched, and in this case the condition may be mistaken for achiria. In the third subvariety the homolateral sensation is the more distinct and if the patient mentions only this one the state of affairs may be thought to be normal.

On the motor side the possible errors in observation are much more important. The motor manifestations, unless analysed carefully, are easily interpreted as clumsiness and weakness. In a unilateral case, when the face, arm, and leg are affected, the resemblance to incomplete hemiplegia is very considerable. All the signs of supranuclear facial paralysis may be present, the gait is typically hemiplegic, and in direct tests of strength, such as with the dynamometer, the conscious effort produces such disproportionately slight results that the presence of paresis may readily be concluded. Again, in the synchiric variety the movements bear a decided resemblance to the synkinesic phenomena of hemiplegia.

It is hardly necessary to remark that all these fallacies can be avoided if the various conditions with their characteristic features are borne in mind.

The significance of dyschiria is totally different from that of alloæsthesia. Although the majority of writers have held that dyschiria, like alloæsthesia, is due to a defect in the excitations that reach the mind from the periphery, the evidence is overwhelming in favour of the view that it is due rather to an incapacity on the part of the mind to appreciate these excitations, which are themselves unimpaired. The following three arguments may be advanced in support of this view.

In the first place, no case of dyschiria has ever been recorded in which the presence of hysteria was excluded. 19 cases have been published of true allochiria; in 16 of these hysteria was the only nervous affection present; in the remaining three there was every reason to suppose, from the other symptoms shown, that hysteria was present in addition to the organic nervous affection. As hysteria is purely a mental affection and certainly is not associated with any defect in the peripheral afferent system, we therefore have strong grounds for supposing that dyschiria is likewise a mental phenomenon. In two cases of hysteria allochiria has been artificially produced during hypnosis, so that here we have positive evidence of its mental origin.

In the second place the remarkable specificity of the phenomenon is most suggestive of its psychical nature. The complete failure of the patient to apprehend the appropriate feeling of "sidedness" in connexion with a cutaneous stimulus contrasts sharply with his power of correctly appreciating all its other attributes, its quality, exact locality, &c. This failure on the one question of "sidedness" stands out absolutely in contrast with the retention of all the other capacities in the same connexion. Never in the hypoæsthesia of organic disease do we find a patient able to differentiate two pieces of cotton-wool of different degrees of coarseness, and localising a touch exactly except for the one fact that he feels it invariably on the opposite side of the body (allochiria), on both (synchiria), or on neither (achiria). The whole picture reminds one irresistibly of the other specific and highly specialised losses that are so characteristic of hysteria.

In the third place, the phenomenon exists only so far as conscious mental processes are concerned. Though the correct feeling of "sidedness" cannot be apprehended in consciousness in the normal manner, so that the various conscious defects occur as described above, nevertheless its presence in the mind is proved by its influence on habitual and automatic processes. The more conscious and volitional is the mental process concerned the greater is the dyschiric defect, while the more subconscious and automatic is the process the less is the defect.

We may therefore conclude that the phenomenon is always of psychical origin and that its presence is almost certain evidence of hysteria. Finally, the recognition of the dyschiric process may aid greatly in the analysis of the defects present and serve as a valuable guide to the discovery of the ultimate basis of the affection, thus proving an important step in that exact psychological diagnosis that underlies all scientific treatment of hysteria.

Harley-street, W.

A PRELIMINARY NOTE ON BOMBAY SPIRILLAR FEVER.

By F. PERCIVAL MACKIE, F.R.C.S. ENG.,
CAPTAIN, I.M.S.; ASSISTANT TO THE DIRECTOR, BOMBAY BACTERIOLOGICAL LABORATORY; CORRESPONDING MEMBER OF THE AMERICAN SOCIETY OF TROPICAL MEDICINE.

Morphology.—The length of the spirillum varies within wide limits; forms from 7·0 µ to 80 or 90 µ are met with. The length of the ordinary individual cell is from 10 to 16 µ, the next most common length is from 26 to 32 µ, and the increase in size goes roughly in multiples of from 10 to 16. Very rarely smaller individuals, as short as 6 or 7 µ, are seen, but whereas this is the rule in the American spirillum (q.v.) it is exceptional in the Bombay form. The width is not greater than 0·5 µ and is generally less. The individual from 10 to 16 µ long may possess as many as six or seven curves, but there is no regularity in the number or excursion of the curves.

In fresh blood the organism is always of corkscrew shape but in films it appears in open curves and is often not more curved than a strand of cotton which has fallen to the ground. The aster or rosette arrangement generally depicted is never seen in natural blood or in vitro. Agglomeration readily takes place but is in the form of wisps or masses of tangled threads. Division takes place transversely, and in deeply stained specimens the dividing line between two daughter spirilla is about interference with the nutrition of the body are unsupported by chemical pathology or clinical experience. Indeed, it was the remarkable evidence I obtained in investigating the remote history of a large number of patients upon whom gastro-jejunostomy had been performed which led me to doubt the accuracy of Joslin's conclusions and to test their correctness by the touchstone of direct experiment.

My first observation was carried out on a man, aged 26 years, five months after I had performed anterior gastro-jejunostomy for gastric ulcer. During the four days which the observation lasted the patient absorbed 91 per cent. of the nitrogen taken in his food and 92·3 per cent. of the fat. Now in a series of metabolism experiments on 75 apparently healthy individuals on a mixed diet, Harley and Goodbody found that the highest nitrogen absorption amounted to 97·07 per cent. and the lowest to 90·1 per cent. of the nitrogen taken in the food, the average absorption being 93·45 per cent. of the nitrogen taken in the food. As regards fats, Harley and Goodbody found that the highest absorption amounted to 98·5 per cent. and the lowest to 90·19 per cent. of the fat taken in the food, the average absorption of 79 observations being 95·05 per cent. If you will compare the results of my observations after gastro-jejunostomy you will see that the nitrogen absorption is 2·4 only below the average and the fat absorption 2·7 below the average, and both nitrogen and fat absorption are higher than the lowest absorption found in a healthy individual. My second observation, also on a mixed diet, seven months after gastro-jejunostomy and suture of a perforated gastric ulcer, showed a nitrogen absorption of 90·5 per cent. and a fat absorption of 92·5 per cent. Comparing these figures with those which I have quoted from Harley and Goodbody you will observe that the nitrogen absorption is 2·9 and the fat absorption 2·5 below the average, but both nitrogen and fat absorption are above the lowest percentages found in healthy individuals. My third observation was likewise made on a mixed diet on a patient two years after gastro-jejunostomy for gastric tetany, and I may mention for the interest of those who regard the functions of the duodenum with reverence, that there existed complete obstruction of the pylorus, so that the food could pass only through the anastomotic opening. During four days on a liberal mixed diet (40 calories for each kilogramme body weight) the patient absorbed 92·1 per cent of the nitrogen taken in the food and 92·7 per cent. of the fat. In other words, the nitrogen absorption was 1·3 and the fat absorption 2·3 below the average, both nitrogen and fat absorption being above the lowest absorption found in healthy individuals. My fourth observation was carried out on a milk diet on a patient two months after gastro-jejunostomy for gastric ulcer. The nitrogen absorption amounted to 92·7 per cent. of the nitrogen in the milk taken and the fat absorption 94·7 per cent. Compared with the average absorption of a healthy person on a milk diet, these figures show a diminished nitrogen absorption of 1·5, and a diminished fat absorption of 1·4, both nitrogen and fat absorption being higher than the lowest percentage absorption found in a normal individual. My fifth observation was made on a mixed diet on a patient one month after gastro jejunostomy for pyloric stenosis. In this instance 92·4 per cent. of the nitrogen and 93·5 per cent. of the fat taken in the food was absorbed, the figures being respectively 1·0 and 1·5 below the average, but both well above the lowest normal absorption.

The preceding observations were made on patients on whom anterior gastro jejunostomy had been performed; the remaining four observations were carried out on patients upon whom I had performed the posterior no-loop method. The sixth observation was carried out on a milk diet one month after gastro-jejunostomy for gastric ulcer. The nitrogen absorption was 91 2 per cent. and the fat absorption 92·3 per cent. of the fat taken in the food—that is, the nitrogen absorption was 3·0 and the fat absorption 3·8 below the average. The seventh observation was made, also on a milk diet, on a patient upon whom I had performed gastro-jejunostomy for duodenal ulcer with partial stenosis. The nitrogen absorption was 92 2 per cent. and the fat absorption 95·4 per cent.—that is, the nitrogen absorption was 2·0 and the fat absorption 0·7 below the average absorption on a milk diet in a healthy individual. My eighth observation was made on a patient upon whom I had performed gastro-jejunostomy for gastric ulcer. The patient was placed on a milk diet and the observation lasted seven days. During this period the man absorbed 93 5 per cent. of the nitrogen, and 94·1 per cent. of the fat taken in the food. In this case the nitrogen absorption was 0 9, and the fat absorption 0·9 below the average. My ninth observation was made on a milk diet on a patient 24 days after gastro-jejunostomy for gastric ulcer. In this patient 92·4 per cent. of the nitrogen and 96·8 per cent. of the fat taken in the food were absorbed; a diminution of 1·8 in the case of the nitrogen, and in the case of the fat an increase of 0·7 above the average.

Taking the whole series of nine observations the average diminution of nitrogen absorption is 1·7 and the average diminution of fat absorption is 1·9, while in every instance the variation is within the limits found in individuals who are in good health. It may be urged that in those cases of this series in which there was no pyloric stenosis, the food passed out through the pylorus rather than through the anastomotic opening. If this be true, although I am not prepared to admit it, it does not affect the conclusions to be drawn from the observations. We know clinically that gastro-jejunostomy has a very beneficial effect on gastric ulcer. This effect is probably due to the diminution of the acidity of the gastric contents which the operation brings about. Which route is taken by the food is a matter of academic interest, as it does not affect the therapeutic value of the operation. The important point is that the short circuit does not appreciably affect the metabolism, whether the pylorus be patent or not, for you will observe that in those patients who have marked pyloric stenosis the absorption after operation is as good as in those in whom the pylorus is patent.

It is interesting to look back and observe how incomplete knowledge leads to the formation of erroneous hypotheses and how as knowledge progresses facts apparently irreconcileable become reconcileable. Pawlow showed that the injection of acid into the duodenum causes a flow of pancreatic juice and that the acid chyme passing through the pylorus acts in the duodenum as the normal stimulus of the pancreatic gland. Since after gastro-jejunostomy the food passes directly into the jejunum, it was urged that after this operation the normal stimulus of the pancreas is absent, with the result that there is a diminished flow of pancreatic juice and consequently a serious impairment of fat absorption. Now Wertheimer has shown that the flow of pancreatic juice can be excited by the introduction of acid into the jejunum, and more recently Bayliss and Starling have demonstrated that the stimulus is not a reflex one but due to a substance which they call secretin, which is conveyed to the pancreatic gland through the blood stream. Therefore, both the hypotheses as to diminished fat absorption and as to the cause of this supposed diminution are now shown to be erroneous. The physiological and chemico-physiological facts as we know them agree, for I hope that I have been able to prove that the digestion and metabolism of the human body are practically unaffected by the operation of gastro-jejunostomy, while the researches of Wertheimer and Bayliss and Starling tell us why the alteration of the route taken by the chyme does not prevent adequate stimulation of the pancreatic gland. Is it not a striking example of the wonderful power which Nature possesses of adapting herself to the altered conditions brought about by surgical intervention?

These chemico-pathological observations are supported by the evidence of clinical experience. May I remind you of one striking fact? As I have pointed out elsewhere, there are at the present time children alive and in perfect health upon whom this operation was performed in early infancy. It is inconceivable that they would have lived for six or seven years and developed into strong healthy children had the operation the harmful effects which have been attributed to it. Lastly, let me say this. Just because gastro-jejunostomy is not in itself harmful there is a danger that we may be tempted to resort to it in doubtful cases in the hope that good may come. Great as is my respect for gastro-jejunostomy, I am no advocate of such a course. To operate for subjective symptoms in the absence of definite clinical and chemical signs is to say the least unscientific. Above all, we must guard against the failure and discredit which result from operation on neurasthenics and on those patients who, as Dr. W. J. Mayo so pithily puts it, "have had their moveable organs fixed, and their removeable ones removed." Such persons as we all know, are often only too ready to tempt fortune farther at the shrine of surgery. Neither gastro-jejunostomy nor any to 24 hours and even under (18 hours). Out of seven monkeys carefully examined daily for relapse three showed reappearance of spirilla (on the seventh or eighth day after the crisis) in small numbers. The remaining four showed none up to the twelfth day. In white rats and mice and in some young black rats the infection has been well marked, as many as up to one spirillum to a field ($\frac{1}{12}$th oil immersion Zeiss, No. 4 Oc.) but the other animals show very light infection, generally about one to 20 fields. In relatively insusceptible animals "watch-spring" forms are common; in these the organism is coiled tightly round a centre and is very inconspicuous. They are never seen in man or monkeys. The infection lasts in the smaller mammals for three, two, or one days according to the susceptibility of the animal. In the cases where relapses have been watched for they have not occurred in any animal except the monkey. Continued passages through wild rats have been tried but both series failed, although as much as one cubic centimetre of defibrinated blood was injected into the peritoneum.[2] In monkeys no special post-mortem feature was noted and on microscopic examination no changes beyond cloudy swelling, hyperplasia of lymphoid tissue, and punctate hæmorrhages were observed. None of the 42 monkeys experimented upon died nor did any appear seriously ill.

Experiment with serum.—By the repeated injection of spirillar blood into a monkey it was hoped that a serum of antitoxic or of spirillicidal potency would be obtained. The method of estimating the degree of this potency was by means of known dilutions of the serum made in Wright's pipettes and by the observations of the effect of the diluted serum on actively motile spirilla in freshly drawn blood. The monkey serum so prepared was found to have the following potency. It produced slowing and agglutination of the spirilla in a dilution of 1 in 20 in 15 minutes, with complete cessation and commencing lysis in one hour. A dilution of 160 produced partial paralysis of spirillar movement without lysis in one hour.

Action on man.—30 cubic centimetres of this serum were obtained from the immunised monkey and were used to inject a patient in the Arthur-road Hospital who had relapsing fever. The man began his first relapse at 6 P.M. on August 13th and on the third day (August 15th) after some preliminary observations to verify the presence of spirilla in the blood, &c., 20 cubic centimetres of the serum were injected intravenously. Hourly observations of blood count, pulse and temperature, and leucocyte counts were made, but until the evening the temperature remained high; the spirilla did not decrease or diminish, though the leucocyte rate rose. 22 hours after the injection and 64 hours after the beginning of the relapse the temperature fell from 104° to 97° F., and the leucocyte count fell from 40,000 per cubic millimetre to 8000, and thereafter the patient remained normal. There were no ill-effects and the second relapse failed to appear.[3] The brother of the patient, one year younger, admitted on the same day with relapsing fever and in the same stage, suffered fever for one day longer and subsequently went through a typical second relapse. It is impossible to draw any deduction from a single case but the result is encouraging.

By the kindness of Dr. Novy of Ann Arbor, Michigan, some specimens of the spirillum Obermeieri which he is investigating[4] were sent and also a small quantity of some highly immunised rat-serum was sent for trial with the Bombay spirillum. On examination of the American spirilla the writer and those in the laboratory who are familiar with the Bombay spirillum were all of opinion that there is an undoubted morphological difference between the two organisms. The American as compared with the Bombay spirillum is shorter in its actual elements and does not form such long aggregations. The shortest individuals are 8 μ and the next most frequent size is about twice that; very long forms from 40 to 60 μ are rare. It is also thinner and more delicate than the Asian form and does not stain so intensely. It does not tend so much to lie in open curves and figures but in typical spirals. The infection is numerically grosser than is met with in the Bombay animals. The American individuals do not tend to lie in wisps of from six to 20 as the others often do. Transverse division is much more plainly marked than in the Bombay organism and the individuals do not tend to remain in continuity so long. Novy's spirillum was stained carefully for flagella and appearances like those depicted by him were well marked. I look upon the terminal filament, in this as in the Asian spirillum, not as a true flagellum but rather as a collapsed sheath left empty by the shrinkage of the cytoplasm. (*Vide supra.*)

The examination of the blood serum sent was additional evidence of the dissimilarity of the two organisms. The serum was stated by Dr. Novy to be of the value of "probably but 100, or at the most 200, units per c.c.[5]" Under his directions, to 4·95 cubic centimetres of defibrinated normal rat blood was added 0 50 c.c. of the serum and the mixture was placed for two hours in an incubator at 37° C. to insure the addition of a normal complement. From this various dilutions of the serum were made with sterile normal saline from 1 in 10 to 1 in 2000, and these were allowed to act (in every case in the same volume) on fresh active spirillar blood. The continuous observation of these under the microscope with controls was conducted for over two hours, and until that time there were no slowing of activity, no rosette formation, no agglutination, and no lysis in any dilution. After 24 hours there was cessation of movement without agglutination or lysis in all the dilutions and controls. In other words, the American antiserum had no effect whatever on the Bombay spirillum. This may be due to one of three causes: (1) the serum may have lost its properties since it left Novy's laboratory; (2) a more specific complement may have been necessary than that supplied by the Bombay rat; or (3) the spirilla may be different varieties.

Investigation into an epidemic of relapsing fever at the Motlibai Hospital.—Under the direction of the Bombay Government a committee was formed (with Lieutenant-Colonel T. E. Dyson, I.M.S., sanitary commissioner with the Government of Bombay, as president and Major T. Jackson, I.M.S., and myself as members) to inquire into the prevalence of relapsing fever amongst the superior staff at the Motlibai Hospital. This hospital is affiliated to the J. J. Hospital and receives lying-in and gynæcological cases. The committee unanimously came to the opinion that the disease was spread in these cases by contact with the fresh blood of women who were admitted for abortion, miscarriage, &c. Many of these cases were in a high state of fever, their blood containing spirilla, and the abortion was a direct result of the disease. During the performance of the necessary treatment the medical officers and nurses contracted the disease possibly through abrasions or cracks which were thus infected with spirillar blood. In other hospitals to which many cases are admitted, but where fresh blood is not encountered at the infective periods of the disease, the menial staff (sweepers) are very rarely affected and the superior staff never.

In reference to the question of identity of the European (Obermeieri), American, Asian, and African spirilla (which has been called into question before and is emphasised by the present paper), it is interesting to note the difference of case-mortality. Rabagliati[6] states, under the head of "Prognosis": "In relapsing fever we know that the mortality is not more than 5 per cent." Dr. Choksy of the Arthur Road Hospital, Bombay, whose experience of the Bombay disease is perhaps unrivalled, has kindly supplied me with the figures of the case-mortality in that hospital for the last seven years. During that period in 3196 cases the average case-mortality was 38 per cent., and taking the annual figures showed a variation from 32 per cent. in 1903 to 43 per cent. of deaths in 1901.

Further investigation into the above and other aspects of the disease is being carried on, particularly with reference to the natural mode of its transmission and to the production of a curative serum.

My best thanks are due to Lieutenant-Colonel W. B. Bannerman, I.M.S., director of the laboratory, for frequent advice and assistance; also to Dr. Sydney Rowlands of the Plague Research Commission; and particularly to Khan able to give from these small figures the general average of twins in this country, yet I am inclined to believe that the ratio of multiparous birth in this country is far below that in Europe.

---

[2] White rats and mice are difficult to procure and still more to keep alive in Bombay, so although they undoubtedly are the most susceptible to the spirillum they have not been used.

[3] Novy has noticed in animals treated with antisera that even if the attack itself is not shortened the effect of the sera is to prevent the relapse appearing.

[5] Novy and Knapp: Ibid., p. 348. "The unit which we employ may be defined as that amount of immune blood or serum which on simultaneous intraperitoneal injection with 0 1 c.c. of rich spirillar blood will just protect a rat 100 gram against infection."

[6] Professor T. Clifford Allbutt's System of Medicine, 1905 edition, article, Relapsing Fever.

While I was looking for an opportunity to make further investigation upon this subject I heard unexpectedly in June, 1901, that Mrs. M—— M——, 36 years of age, who lived in Hama-cho, Tokyo, had had twins in the year 1900 and then triplets the year following. Upon examination I found, as I expected, one supernumerary gland on the anterior wall of each axilla, and upon squeezing I obtained milk from both of them. Ever since then I have been earnestly studying multiparous birth, and up to the present time, directly or indirectly, 24 cases have come under my observation, including twins, triplets, quadruplets, quintuplets, &c. Out of these 24 cases 16 had supernumerary glands and the remaining eight not, showing the ratio of 66 66 of polymastia among 100 cases of multiparous birth Again, out of 11 cases of the total number who had twins nine were subjects of polymastia (81·81 per cent.), and out of the remaining 13 cases who had triplets, quadruplets, and quintuplets seven were subjects of polymastia (53·84 per cent.).

By these facts, and also those which I am going to mention hereafter, I was finally enabled to prove that those who are subjects of polymastia have a tendency to become more frequently pregnant than those who have not. From my own observation, out of 85 women who are subjects of polymastia and had passed more than ten months after marriage I obtained the following results: Those who were already pregnant, 71 (i.e., 83·52 per cent.); and those who are not yet pregnant, 14 (i.e., 16·47 per cent.). Again, from my own observations in the gynæcological department of the Japan Red Cross Hospital, 1905–06, I obtained, out of 727 women who were subjects of polymastia and had passed more than ten months after the marriage, the following: Those who were already pregnant, 523 (i.e., 71·93 per cent.); and those who are not yet pregnant, 204 (i.e., 28·06 per cent.). Having these figures in view we should be able to form an estimate of how much more frequently those who have supernumerary glands become pregnant.

In an article written by Dr. M. Ogata, the director of Ogata Gynæcological Hospital, Osaka on the Mamma of the Japanese Women,[2] we find the following item as to the relation of polymastia to pregnancy: "Out of 13 married women having polymastia we have: Those who were already pregnant, 12 (i.e., 92·30 per cent.); those who are not yet pregnant, 1 (i.e., 7·70 per cent). Out of the married women not being subjects of polymastia we have: Those who were already pregnant, 55·90 per cent.; those who are not yet pregnant, 37 90 per cent.; those who had abortion, 6·20 per cent. Judging from the above figures, it seems that those who have supernumerary mammary glands or nipples are more likely to become pregnant." Moreover, out of 101 married women who had supernumerary glands, I myself met with 18 cases of multiparous births—i.e., 17·82 per cent. This is, however, the result I obtained upon examining the subject of polymastia from the point of view of multiparous birth, and can therefore not be taken as the ratio existing between polymastia and multiparous birth in general. In this country where the cases of multiparous birth are comparatively few, the fact that they are found more frequently among those who are subjects of polymastia is a sufficient proof that there is a relation between them, and although this subject still remains one of controversy among scientific men, I do not hesitate, from my own observation, to assert that such is the case. The following is the description of the cases I have met with:—

CASE 1.—Mrs. T—— F——, 35 years of age. In November, 1901, she gave birth to quintuplets. Having had previously eight children these made in all 13 Upon examination I found one supernumerary gland on the anterior walls of both right and left axillæ The one on the right was considerably developed. On squeezing both were found to secrete thin milk.

CASE 2.—Mrs K—— O——, 37 years of age. In June, 1903, she had quadruplets, and previously three children making in all seven. Upon examination no trace of polymastia could be found.

CASE 3.—Mrs. M—— M——, 36 years of age. In June, 1901, she had triplets, twins the preceding year, and five children previous to that, making in all ten children. Upon examination I found one supernumerary nipple on the anterior wall of either axilla, and by squeezing obtained the secretion of milk.

CASE 4.—Mrs. H—— K——, 32 years of age. In July, 1901, she had triplets, and previously five children, making in all eight. Upon examination I found one supernumerary gland on the anterior wall of either axilla, one upon the left mamma, one on the underside of the right mamma, and one in the right axilla, making in all five supernumerary glands. From the one upon the left mamma and the one on the anterior wall of the right axilla milk could be obtained by squeezing.

CASE 5.—Mrs. O—— Y——, 26 years of age. In August, 1903, she had triplets for the first time. Upon examination one supernumerary gland was found on the anterior wall of the left axilla, but no secretion could be obtained by squeezing.

CASE 6.—Mrs. T—— K——, 27 years of age. In March, 1902, she had triplets, and previously four children, making in all seven. Upon examination I found under the skin of the anterior wall of the left axilla a gland of the size of a small pea (1½ centimetres above and external to the normal breast). At the corresponding place on the right a faint trace of the same thing was visible.

CASE 7.—Mrs. H—— O——, 39 years of age. In June, 1902, she had triplets, and previously six children (six times prematurely born), making nine in all. Upon examination I found four distinct glands—one on the anterior wall of the left axilla, one in the left axilla itself, and two on the anterior wall of the right axilla. The bunch of glands could be felt under the skin but no secretion could be obtained by squeezing.

CASE 8.—Mrs. S——, 33 years of age. In November, 1901, she had triplets, and previously two children, making in all five. Upon examination I found one supernumerary gland of one-half the size of a grain of rice on each side of the linea alba, three and a half centimetres from it and about two centimetres below the lower edge of the rib. (As I was unable to examine this case personally I mentioned it to Dr. M. Imai, the director of Nagano Hospital, who sent his assistant to examine the subject and obtained the above report.)

CASE 9.—Mrs. M—— O——, 30 years of age. In June, 1905, she had triplets, and previously four children, making in all seven. Upon examination I found a flat and hard bunch of the size of an egg under the skin of the left axilla. She had never felt its existence until two or three days before the parturition. Judging from its form I considered it to be a ductless mammary gland under the skin. She informed me, moreover, one month after parturition that the said bunch had entirely atrophied.

CASE 10.—Mrs. S—— M——, 29 years of age. In March, 1902, at the seventh month, triplets were born to her dead; she had previously to that six children, making in all nine. Upon examination no trace of polymastia could be found. (This, again, I was unable to examine personally, so I asked Dr. K. Mizuno the medical man in attendance, through my friend Dr. T. Hayashi who happened to be in Tokyo from that district, and obtained the above report.)

CASE 11.—Mrs. T—— A——, 27 years of age. In April, 1902, seven years after her marriage, she gave birth to triplets. Upon examination no trace of polymastia was found in her.

CASE 12.—Mrs. T—— K——, 36 years of age. In September, 1901, she had triplets, and previously five children, making in all eight. Upon examination no trace of polymastia was found.

CASE 13.—Mrs K—— K——, 31 years of age. In August, 1903, she had triplets, and previously three children, making in all six. Upon examination no trace of polymastia could be found.

CASE 14.—Mrs. Y —— A——, 30 years of age. In March, 1902, she had twins, and previously three children, making in all five. Upon examination one supernumerary gland was found in the left axilla and two each on the anterior wall of each axilla. The secretion of milk was obtained from two of those on the left and from one on the right.

CASE 15.—Mrs. I—— H——, 39 years of age. In December, 1901, she had twins, and previously eight children, making in all ten. Upon examination there was an indistinct supernumerary gland on the anterior wall of the left axilla and a prominent one at the corresponding place on the right.

CASE 16.—Mrs. N—— A——, 37 years of age. In May, 1902, she had twins, and previously four children, making in all six. Upon examination one supernumerary gland was found on the anterior wall of each axilla; they were dark in colour, and even after four months, by squeezing, I could obtain thin milk from them.

CASE 17.—Mrs. K—— K——, 22 years of age. Soon after she married J——, a younger brother of Mrs. N—— A—— (mentioned in Case 16), she had two children, and in May, 1902, she gave birth to twins, but after parturition both the mother and the twins died. I found upon examination that the father of these twins has a remarkable supernumerary gland on the anterior wall of the right axilla. Upon examination of Mrs. M—— K—— (57 years of age), the mother of Mrs. N—— A—— and J——, I found one supernumerary gland on the anterior wall of the right axilla. From this it is clear that the condition of polymastia in Mrs. N—— A—— and J—— is one inherited from their mother, while the multiparous birth in Mrs K—— K—— is probably to be sought for in the polymastia of her husband J—— and in his mother M—— who herself had the pretty large number of eight children.

CASE 18.—Mrs. S—— K——, 26 years of age. In June, 1901, she had twins. When she was a nurse in the Red Cross Hospital (November, 1894), I found that she had one supernumerary gland on the anterior wall of each axilla, and after she was married I heard that she had twins.

CASE 19.—Mrs. T—— Y——, 36 years of age. In July, 1896, she had twins, and previously four children, making in all six. Upon examination there was a trace of a supernumerary gland on the anterior wall of the left axilla, but nothing was found on the right. (This case was observed by Dr. K. Aoki of Atsugi, Kanagawa-ken, and was reported to me.)

CASE 20.—Mrs. H—— A——, 32 years of age. In 1903 she had twins, and previously three children, making in all five. Upon examination a remarkable condition was found of supernumerary glands on the anterior wall of each axilla, 13½ centimetres distant from the normal mammæ.

CASE 21.—Mrs. S——, 43 years of age. In July, 1905, at the fifth month, twins were born to her dead; she had previously to that five children, making in all seven. Upon examination I found one supernumerary gland on the anterior wall of the right axilla, nine centimetres distant from the normal mamma.

CASE 22.—Mrs. S—— N——, 43 years of age. She gave birth to twins in 1884 when she was 24 years of age; she had previously two children, making in all four. Upon examination no trace of polymastia could be found

CASE 23.—In April, 1902, after my communication on polymastia at the first meeting of the Japanese Union Medical Society, Dr. S. Shishido, of Kariya, Mikawa, told me of the following case: "There not merely passive; the removal of the bone on which the pressure is exerted is effected by the setting up of a subacute inflammation in the bone so that a rarefaction results.

[2] Guide to Midwifery, No. 65, October, 1901.

Dr. Nicholls has also contributed a valuable article on Tumours and Tumour Formation, though we must demur to one distinction made between granulomata and true tumours, for we are told that the granulomata can be traced to a definite cause, while a tumour is "due to no demonstrable cause." A "differentia" which depends on our ignorance cannot be of much importance. Dr. T. A. McGraw of Detroit has written an interesting article on Theories of Tumour Formation, and Dr. H. R. Gaylord has contributed a valuable account of the parasitic relations of cancer. Especially valuable is that part of it entitled "Characteristics of the Unknown Stimulus in Cancer."

Dr. J. C. Bloodgood's description of surgical shock is excellent. But on one point we are not fully in accord with him, and that is as to the temperature at which saline solution should be injected. It is most important that the body should not suffer any reduction of temperature by the injection, whether it be subcutaneous or intravenous. The temperature of the abdominal viscera is 100° F., and therefore it is not correct to say that the saline solution should be raised to a temperature between 100° and 105°, and then poured into a glass infusion apparatus with a long piece of rubber tubing. A fall of two or three degrees is sure to occur and the temperature of the infused liquid may really be below that of the body, a condition which must produce depression. Dr. J. D. Bryant's article on General Surgical Diagnosis is excellent, as might have been anticipated. The Radiographic articles are written by Dr. Preston M. Hichey of Detroit, Mr. W. J. Dodd, and Dr. R. B. Osgood of Boston, and especially would we commend the section on the interpretation of radiographs and that on the radiographic interpretation of the epiphyses. Dr. J. E. Moore's description of the general principles of surgical treatment contains a good account of the practice of aseptic surgery.

In the second volume Dr. V. P. Gibney writes on Tuberculosis from a Surgical Standpoint, and Dr. E. L. Keyes, jun., on Syphilis from a Surgical Standpoint. In the latter article the author attempts to distinguish syphilitic ulcers of the leg from varicose ulcers by the situation—a very untrustworthy guide. We cannot agree with him that "mercury by hypodermic injections is the surest, swiftest, safest treatment of the symptoms of syphilis." This statement is much too absolute. Why, too, does he speak of "the symptoms of syphilis" and not of the disease itself? Curiously, a little later the author speaks of "the inconvenience and danger" of hypodermic treatment. In Dr. D. W. Mongomery's account of the Surgery of the Diseases of the Skin we find a very good description of this portion of surgery and it is well illustrated. There are several other articles of interest in this volume and we may mention specially Surgical Diseases of the Lymphatics by Dr. C. N. Dowd of New York.

We may say that we have formed a high opinion of this work. The articles naturally vary somewhat in merit but we have not found one unworthy of its position in this treatise. We hope the succeeding volumes will equal those which we have already seen.

The World's Desires, or the Results of Monism. An Elementary Treatise on a Realistic Religion and Philosophy of Human Life. By EDGAR A. ASHCROFT. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1905. Pp. 440. Price 10*s.* 6*d.* net.

THE volume before us is dedicated to Ernst Haeckel and represents an endeavour to apply the Haeckelian form of monistic philosophy to the problems and conditions of everyday life and thus to afford at once a philosophy and a religion to those who having regretfully lost their hold on the dualistic philosophies and revealed religions are yet altruistic at heart and desire an optimistic spur to endeavour. The fundamental basis of this philosophy is realism, its central and essential mechanism "the conscientious observation by the human senses of the complicated facts of the universe as interpreted by the nerve organisms." Such a religion, Mr. Ashcroft maintains, would be a progressive one, for by means of observation, empirical experiment, and objective reasoning it would incorporate and assimilate the advancing knowledge of mankind. It would at once discard all revelation and banish emotion and sentiment from the general religion. Perhaps the main principles may best be given in Mr. Ashcroft's own words: "The aim and object of philosophy and of its twin sister religion therefore in our realistic system, is the cultivation of a true understanding of the veritable conditions of human existence, so that this knowledge may be safely applied to the practical direction and guidance of the life of the individual and of the community; and with such ends in view to the determination from time to time of reasonable and tenable ideas and standards of ethics and practice for general and individual application; the whole being for the purpose of securing the happiness of mankind and promoting systematic development of the race to higher and higher things in due accord with its potential characteristics." Mr. Ashcroft recognises the limitations imposed on our knowledge of the universe by the limited capacities of the observing mechanism—the senses and by the finite limits of our reasoning powers, but he foresees the time when the application of the scientific method more thoroughly to the ordinary affairs of mankind will result in advances more rapid and utilitarian than even at the present time. When he allows his constructive imagination full scope and sketches forth a scheme of Utopian happiness to which mankind may at last attain on realistic lines, he writes with real enthusiasm; he confesses, however, that faith is a psychological attribute as necessary to the man of science as to the devotee. Like all monistic thinkers, Mr. Ashcroft is from the very nature of his philosophy an iconoclast, and though, like his master Haeckel, he is uncompromising, direct, and relentless in his opposition to any suggestion of dualism or of revelation, he is resolute to retain the ethical, the beneficial, and the altruistic features of existing creeds.

The book is divided into four parts. Part I. deals with the problems of human life and thought and here Mr. Ashcroft outlines the general principles of his realistic philosophy and its application to form a religion of realism. He points out that the realistic position is practically a development of that of Aristotle, the dualistic or theistic being analogous to that of Plato. He shows how in recent times Comte in France and Herbert Spencer in England have endeavoured to apply human knowledge to the instincts and desires of humanity, while the most complete application of monistic philosophy to this purpose is that of Haeckel, and thus he claims no novelty for his work which is to present in simple form the application of human knowledge in its present state to the physical and spiritual needs of man. Part II. is devoted to our knowledge of the material universe and deals with the nature, origin, and destiny of human knowledge. It contains an interesting presentation of our present knowledge of the cosmos, of the material sciences such as chemistry, physics, and astronomy, and of their relation to mankind and his organisation. It deals with the application of science to the needs of man, with the advances already made by applied science and those confidently to be expected. Part III. is devoted to the human organism and organic life and deals with some of the fundamental problems of biology, including the nature of life. The remainder of this part is devoted to a brief presentation of the anatomy and physiology of the human organism. This section is the one disappointing one, for in his desire and a paroxysmal colicky pain immediately preceding, and always relieved by, defæcation.

The ætiology of the disease is somewhat doubtful but many important factors can be adduced to show that mucous colitis is rather due to a disease of the nervous system than to a local condition of the colon. It is certainly found more commonly in the upper and middle classes than amongst the poor. In this connexion I may add that the records of all the patients treated in the London Hospital for the past five years have been carefully looked through, and only 20 cases have been collected, and of these 20 cases many were patients of independent means. Mucous colitis occurs much more commonly in females than in males; my own cases show that 72 per cent. were females. Other writers such as Hale White[1] found 85 per cent. of his cases were females, whereas Nothnagel,[2] von Noorden,[3] and others state the percentage as 70 to 80. It is a disease which first makes its appearance in early adult life; thus to analyse the cases before us:—Between the ages of 10 and 20 years, 4 cases; between 20 and 30 years, 5 cases; between 30 and 40 years, 10 cases; between 40 and 50 years, 2 cases; between 50 and 60 years, 2 cases; and between 60 and 70 years, 2 cases. Among my cases the earliest age at which the first symptoms of mucous colitis appeared was 17 years. In the two cases over 60 years of age, the age at which the first symptoms appeared is a little doubtful, but both patients are known to have been extremely constipated as long as they can remember, and they have both been under a medical man's care for the passage of mucus for many years. Hale White[4] found in 60 cases that the symptoms very rarely appeared in patients under 20 years of age, but most frequently in patients between the ages of 20 and 30 years. Boas[5] and others say that the majority of cases occur between the ages of 20 and 40 years. Seeing therefore that all authors are agreed that mucous colitis is a disease of early adult life, great care is needed to determine if we are dealing with a true case of this disease or not when the first symptoms appear at the age of 45 or more years. According to von Noorden[6] the disease does not seem to be equally prevalent in all localities, for in his list of cases Russians appear to predominate.

Most authors agree that constipation is one of the chief ætiological factors and my statistics show that in this disease constipation is extremely common; thus 84 per cent. of the cases suffered from constipation, but on careful examination it was found that 56 per cent. had constipation before the mucous colitis appeared, whereas 84 per cent. had constipation during the attacks. This would show that although in a great many cases constipation preceded the attack it was more frequent during the attack and must therefore be looked on rather as a symptom of mucous colitis than as an ætiological factor. With regard to diarrhœa little need be said, as very few of the patients suffered from it to any extent. 20 per cent. had diarrhœa before the attack, 8 per cent. had diarrhœa during the attack, and 8 per cent. had diarrhœa before the attack followed by constipation during the attack. These figures show that the disease is only very slightly associated with diarrhœa, but a few of the patients who suffered from diarrhœa before the attack were constipated during the attack.

The nervous temperament of the patient seems to play an important rôle in the causation of the disease. Thus 64 per cent. of my cases showed marked instability of the nervous system in the form of neurasthenia, hysteria, attacks of nervous prostration, &c. 24 per cent. showed various reflex phenomena, such as alternate flushings and coldness of the head and face, or of the feet, with excessive sweats, catches in the voice, and attacks of palpitation, which in one of my cases are very severe and are accompanied by pain in the chest which might almost be looked on as pseudo-angina pectoris. These reflex phenomena frequently end by the patient going to stool or by a copious eructation. Langenhagen[7] lays great stress on these reflex phenomena. He says: "The reflexes go from the irritated intestine by means of the bulb and thence by that of the pneumogastric nerve or the sympathetic system and reverberate upon the most diverse organs, especially the heart, with more or less violent fits of palpitation occurring frequently after meals, irregularity of beat, and even attacks of pseudo-angina pectoris. These attacks are often terminated by a stercoraceous evacuation or a copious eructation and the patient is relieved." The terminal threads of the vagus in the lungs are also apt to be affected in this way, for he has frequently remarked attacks analogous to those of asthma, excepting that they are of an inverse clinical type. The thorax is in a way immobilised in the act of expiration and there is great difficulty in making the inspiratory movements. He goes on to say that "If the irritation caused by the muco-membranous affection of the intestine can produce such repercussion, there must be in such cases a sort of special temperament, a nervous diathesis, an exaggerated impressionability and susceptibility of the entire nervous system." Von Noorden[8] states that the great majority of cases give a history of previous digestive disturbance for a long period preceding the onset of mucous colitis. My statistics show that 76 per cent. of the cases suffered from various disorders of the stomach before the symptoms of mucous colitis made their appearance. The chief gastric troubles were pain and vomiting after meals, flatulence, and hyperacidity, while a few cases had gastric ulcer. Glénard[9] and Langenhagen[10] lay great stress on enteroptosis as an etiological factor, but in my cases 12 per cent. only showed this abnormality, and therefore it would appear that enteroptosis does not play such an important part in the causation of mucous colitis as has been ascribed to it.

In a large number of cases mucous colitis is preceded by affections of the uterus and appendages, and these are of the most diverse nature. In my list of cases no fewer than 36 per cent. had some trouble with the organs of generation, dysmenorrhœa being the most common, while 16 per cent. attribute their illness to a miscarriage. It is difficult to see in what way these affections of the uterus and its appendages can produce mucous colitis, still there is little doubt that the nervous system can be very much affected by even a trifling ailment in these organs. Moreover, as the anatomical relations of the generative organs and rectum are very close, disease of the former may easily affect the latter and particularly in restricting the natural movements of this portion of the bowel in consequence of the formation of adhesions. A few of the cases in my series had suffered for years with appendicitis and had had appendicectomy performed. In one case the mucous colitis came on two years after the operation, and in the others the patients ceased to pass mucus and have remained free from signs of mucous colitis since. These facts show that the symptom-complex of mucous colitis may follow and possibly result from some focus of irritation in the abdomen. In this connexion it will be seen that mucous colitis bears a striking resemblance to asthma. It is well known that in persons who show a predisposition towards asthma some form of irritation to the nasal mucous membrane, however slight in intensity, will precipitate an attack. I have frequently noticed this close relationship between nasal irritation and the development of asthma, for in this neighbourhood affections of the nose are common, such as rhinitis sicca, hypertrophic rhinitis, &c., and there are also not a few cases of asthma. Moreover, in the early summer, when there is an abundance of small particles in the air, either dust or pollen, nasal catarrh is very prevalent and in the more severe cases asthma follows.

The cases of mucous colitis associated with appendicitis appear to fall into two groups—namely, (1) those in which the appendicitis is only part of the mucous affection of the rest of the intestine; and (2) those in which true appendicitis precedes the onset of mucous colitis. It may be stated here that where appendicitis appears only as a part of the mucous colitis, operation will not cure the disease of the colon, whereas appendicectomy in the other type of case may possibly exert a very beneficial influence and ultimately be followed by a complete cessation of the symptoms of mucous colitis. In only one of the cases can a history of previous gall-stones be obtained. Four of my patients had suffered from dysentery some years before the first appearance of the symptoms of mucous colitis.

Pathology.—As mucous colitis is never of itself fatal the number of post-mortem examinations is limited. There are on record a certain number of cases which have at some period or other of their lives shown signs of having had the

The subject-matter is thoroughly up to date and the pages are singularly free from printer's errors. The present edition thoroughly maintains the standard of its predecessors and forms an excellent and a comprehensive work of reference on all that pertains to pharmacy and the collateral arts.

LIBRARY TABLE.

Das Dysenterietoxin. (*The Toxin of Dysentery.*) By Dr. ROBERT DOERR. With two Graphic Curves in the text and a Plate. Jena: Gustav Fischer. 1907. Pp. 75. Price 2.50 marks.—This work gives us a very complete *résumé* concerning the bacillary toxin of dysentery. The author has come to the following conclusions. The bacilli of the disease of the Kruse-Shiga type secrete a true soluble toxin, whilst those of the Flexner type do not. By extraction in a solution of common salt from fresh agar cultures and subsequent filtration a highly toxic solution is formed, and in this the intensity of action of the toxins is dependent on the one hand on the nature of the source from which it is obtained, and on the other on the degree of alkalinity of the culture medium, whilst the amount of toxin present shows a certain parallelism with the reaction of the latter—that is to say, that the greater the alkalinity of the culture fluid the greater the amount of toxin. Another point determined was that the formation of the pellicle is at the same time an indication of a rapid formation of toxin. The latter likewise is seen not to be affected by heat to the extent of withstanding for an hour's duration a temperature of 70° C., but is quickly destroyed when the latter reaches 80° C. It suffers no harm from trypsin, bile, or the succus entericus. Mineral acids remove the toxicity from filtered bouillon cultures, but if these be neutralised by alkalies the toxicity again becomes evident. This toxin of dysentery was found to affect strongly rabbits, cats, dogs, and monkeys, whilst guinea-pigs, white mice, fowls, and doves were refractory to it. Again, with susceptible animals the author often found that after intravenous, subcutaneous, or intraperitoneal injection a hæmorrhagic and necrosing inflammation of the mucous membrane of the intestine followed the secretion of the poison by the latter, whilst there were certain constant lesions of the nerve centres to which after receiving the corresponding dose the animals succumbed. The most suitable animal for experimental research is the rabbit, which reacted in one-third of the cases experimented upon, showing a hæmorrhagic-diphtheritic typhlitis, the small intestine, however, not showing any lesion, similar to cases in men. The secretion of the poison takes place through the gut and in a less degree through the kidneys but no evidence of the poison being secreted by the liver could be ascertained. The bite of animals showing marked symptoms of poisoning by the toxin was always atoxic. Lastly, the occurrence of experimental typhlitis was found to be quite independent of the entrance of the bile into the intestine. The results shown above are the outcome of a laborious amount of honest work. The author has given us a valuable addition to the literature of the subject on which he has written.

Medical Diagnosis: a Manual for Students and Practitioners. By CHARLES LYMAN GREENE, M.D., Professor of the Theory and Practice of Medicine in the University of Minnesota, &c. With seven coloured plates and 230 illustrations. London: Rebman, Limited. 1907. Pp. 683. Price 13*s.* 6*d.* net.—It is rather difficult to criticise this book, as its contents do not entirely correspond with its title and it is therefore open to blame for failure to carry out its implied promise, while at the same time it deserves praise for its actual merits. Frankly, it is not quite what we expect in a book which professes to be concerned only with diagnosis; it deals with diseases *seriatim* as do most text-books of medicine, rather than grouping the phenomena of diseases under symptoms as they present themselves to the physician and analysing the varied conditions which may underlie these outward signs. Etiology, morbid anatomy, and symptoms are all considered, though rather more space is given to diagnosis than is often the case. As a manual of medicine for students, and indeed for practitioners, the book has merits of its own. It is packed with information, generally conveniently arranged, and reference is facilitated by headings in dark type and by the use of italics for important statements. There are in addition marginal notes of the contents of paragraphs, which are often useful, though we doubt whether much is gained by such a sign post as "a ghastly clinical picture," which we find as the only marginal note on one page. The style is generally clear, Here and there, however, we meet with solecisms such as "emphysemae" and "a phenomena," and compression is sometimes carried to such a point as to make a sentence almost unintelligible so that we feel that we are reading a précis rather than a treatise. Still, the total result is a book which may be distinctly useful to those about to undergo an examination in medicine.

Sea-Sickness, its True Cause and Cure. By H. NORMAN BARNETT, F.R.C.S. Edin. London: Baillière, Tindall, and Cox. 1907. Pp. 39. Price 1*s.* 6*d.*—This is an interesting and valuable little book, although its conclusions are not so new as the author apparently supposes. That sea-sickness is due to the loss of the sense of position which is in some way connected with the semicircular canals was taught in at least one medical school some 25 years ago and the bromides were recommended for the prevention of sea-sickness in a letter from Mr. H. Saunders which was published in THE LANCET of June 14th, 1879, p. 867. But although, as we have said, the theory of sea-sickness put forward by Mr. Barnett is not new it is still none the less true and, as even now it does not seem commonly to be recognised, we think he has done the profession service by bringing out the book before us.

Lehrbuch der Anorganischen Chemie. (*Text-book of Inorganic Chemistry.*) By Professor H. ERDMANN. Fourth edition. Brunswick: Friedrich Vieweg und Sohn. 1906. Pp. 796. Price 15 marks.—The feature of this fourth edition of a well-known German text-book is the care which the author has taken to include a quite modern account of recent researches on the rare gases of the atmosphere and of radium. Otherwise the presentation of principles and facts remains the same and we still entertain the favourable opinion of the author's manner of dealing with the subject which we expressed when reviewing previous editions. The book is admirably illustrated and contains also tables of logarithms and the disposition of elements in accordance with the periodicity of their functions.

JOURNALS AND MAGAZINES.

The Scottish Medical and Surgical Journal.—In the September number of this journal Dr. W. B. Drummond gives a thoughtful review of the work of the recent Congress on School Hygiene and discusses some of the problems raised as they affect Scotland in particular. His advice is so to organise the system of medical inspection of school children that the local authorities may not be tempted to offer illusory salaries to part-time officers already in practice. Dr. D. Barty King writes on *Muco-membranous* Colitis and endeavours to classify the conditions found in this group of affections, and Dr. A. Dingwall Fordyce continues his article on Infant Feeding, dealing with cow's milk in the light of recent researches on its coagulation. Dr. B. P. Watson records a case of repeated abortion due to syphilis, in which treatment with potassium iodide was followed by the birth of a child with congenital goitre; he notes the cases already on record in which this condition followed the administration of potassium salts but concludes that the goitre is probably due to some maternal toxæmia.

passed, consisting of reddish-brown grains varying in size. This particular sign has been observed in two of my cases. Langenhagen[23] and Hale White[24] have observed intestinal gravel in the stools of their patients and, according to Langenhagen, the chemical composition of the sand is nearly always constant and consists of a fundamental organic matter mixed with salts of lime in variable proportion. They are usually the phosphates and carbonates of lime and sometimes crystals of ammoniaco-magnesian phosphate are to be met with. Hale White's analysis shows the principal inorganic constituent to be calcium oxalate. Langenhagen and Hale White also point out that the fæces may be very pale and I have noticed this condition on three occasions in one of my patients, the stools consisting of greyish material, and in this particular case, after taking one or two doses of castor oil or other aperient, there has been a copious discharge of dark brown bile which is extremely irritating to the skin round the anus.

Having considered at some length the character of the stools we will next pass on to study the other cardinal symptom—namely, the abdominal pain. This varies very much, on the one hand, according to the severity of the attack, and, on the other hand, with the individual sensibility. The abdominal pain is of two kinds: firstly, there is in some cases a dull constant aching pain felt chiefly in the lower part of the abdomen, which is occasionally relieved by pressure but for the most part unaltered. And, secondly, paroxysms of severe colicky pain which may be so intense as to make the patient vomit, or sweat, or writhe in agony; and this is usually associated with a desire to go to stool, and is nearly always relieved by the passage of fæces, even if the motion only consists of slime or blood and slime. This paroxysmal sharp pain is more characteristic of mucous colitis than the constant dull ache, and is probably caused by the violent peristaltic movements of the bowel to expel or to separate the tough gelatinous mucus from the wall of the intestine. Occasionally there is tenesmus, but very rarely. An examination of the abdomen during an attack of mucous colitis reveals certain very important facts. In the first place, the abdominal parietes are nearly always flabby. It is unusual to find the abdomen either much distended or much retracted. There is nearly always a certain amount of deep tenderness over the colon either throughout its whole length or over a certain portion of it. In the majority of my patients deep tenderness was most marked over the sigmoid flexure. In a large number of cases the colon can be felt and the condition varies between spasm and atony, so that in any one case the two conditions may be met with—namely, spasm in one part and a flatulent distension in another. Hard fæces can often be felt in the sigmoid flexure. Another sign which is occasionally met with is the splashing sound on dipping suddenly with the fingers, and this is most often elicited in the transverse colon, which in some cases is dragged down very much below the umbilicus. Gurgling can frequently be felt along the whole course of the colon. The stomach is occasionally found to be dilated, but not commonly, as this was only found to be present in two of the cases of this series. Glénard[25] states that in 50 per cent. of the cases of mucous colitis there is a marked diminution in the size of the liver and that in only from 2 per cent. to 3 per cent. is it enlarged. My cases do not bear out this statement, for in none of them was there any diminution in the liver dulness, and in two cases the liver was definitely enlarged. An examination of the rectum with the finger usually reveals nothing except hard fæces and sometimes the presence of hæmorrhoids. A sigmoidoscopic examination is also negative.

The signs and symptoms of patients between the attacks of mucous colitis vary very much, but, as a rule, constipation and flatulence predominate. The tongue is usually coated with a whitish or light brown fur. The breath is usually offensive. There is, as a rule, dyspepsia of one kind or another, with loss of appetite; and these two factors usually lead the patient to deprive himself of first one article of food and then another until his diet is so restricted that it is not sufficient to meet the ordinary demands, and so the patients are often thin and wasted. As has been stated before, the patients are usually sufferers from neurasthenia or other nervous troubles. A large number of them, especially when they have suffered from mucous colitis for some length of time, become hopelessly neurotic and take a daily and increasing interest in their stools, and may almost be said to love their complaint. This is the class of patient one hardly expects will recover from the disease. In one of my cases the passage of large quantities of mucus in the urine was noted. In none of my cases was the temperature raised above 99° F., but in the majority the temperature was slightly subnormal and the charts do not show any marked rise or fall. Therefore the clinical symptoms can hardly be said to point to an inflammatory origin.

Diagnosis.—As mucous colitis is not a common disease, and, moreover, occurs in neurotic and dyspeptic individuals who greatly exaggerate their symptoms, it is quite possible that some cases occur which are not correctly diagnosed; therefore every care should be exercised to make a thorough examination of the abdomen and stools in a doubtful case. The patient should be kept in bed and carefully watched for some time, repeated examinations being made of the abdomen, character of the stools, &c., and the bowels well emptied by enemata. In all cases digital and bimanual examinations of the rectum should be made. Mummery[26] strongly advocates the use of the electric sigmoidoscope to exclude the possibility of malignant disease, and also to investigate the condition of the mucosa. The diseases which might be mistaken for mucous colitis are not many in number; amongst the more common may be mentioned:—(*a*) Local conditions in the rectum, such as rectal polypi, carcinoma, tuberculous ulceration, actinomycosis, or simple fibrous stricture. In all these cases a careful examination should reveal the true condition. (*b*) Affections of the colon, such as simple catarrhal colitis, ulcerative colitis, and dysentery. There should not be much difficulty in arriving at a correct diagnosis, for in all these diseases diarrhœa is a prominent symptom, and, moreover, they are all associated with pyrexia of greater or less degree, whereas in mucous colitis it is exceptional to find the temperature above normal, at any rate, for any length of time, and constipation is one of the most prominent symptoms. The character of the stools should be a valuable guide, and the absence of marked tenesmus, and in the case of dysentery the absence of the amœba or of Shiga's bacillus in the stools, should be of much assistance.

With regard to the prognosis, one may say that by itself mucous colitis practically never ends fatally. Hale White[27] states that of his 60 cases 50 per cent. got well, from 10 to 12 per cent. were much improved, and 37 per cent. did not improve; the list of cases which did not improve is entirely made up of females and therefore there is no doubt that the disease is more severe in women than in men. It is important to note that nearly all these cases had had the disease for some considerable time before treatment was commenced, which forms a strong argument in favour of early recognition and treatment. These observations are fully confirmed by my own list of cases, but now that the disease is becoming more recognised, both with regard to its etiology and pathology, one cannot help thinking that the percentage of patients who ultimately completely recover will be even greater than 50 per cent.

The treatment of mucous colitis resolves itself into that for the relief of the attack itself, and that calculated to remove the cause of the disease. We will first consider the treatment of a patient suffering from a definite attack, and here the chief symptoms which require relief are the pain and constipation. Now, as we have decided that the pain is entirely due to efforts on the part of the bowel to remove the mucus which has been secreted into the intestine, our treatment must be directed to the bowel to help it completely to evacuate its contents. This may be attained in two ways—namely, by the use of aperients and by enemata. The aperient which has been of most service in the cases which have come under my own observation is certainly castor oil, and it should be given in fairly large doses and repeated frequently; thus it has been my practice to order doses of half an ounce to be given three times a day until the passage of mucus ceases, and then to be diminished to half an ounce daily. In a few cases there seems to be a great objection to the use of castor oil on account of its nauseating propensities, and in these cases I have substituted calomel in doses of two grains three times a day. Enemata of ordinary soap and water, or containing four or five ounces of olive oil, have certainly been beneficial and have materially assisted the aperient in its action, and in cases where

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 21, 1907.

Rural Sanitation.

EARLY in the last session of Parliament Sir JOHN DICKSON-POYNDER moved in the House of Commons for a return "of the medical officers of health and inspectors of nuisances in the rural districts of each county in England and Wales, showing the area and population of each district and, as regards each officer, the amount of his remuneration, whether repayment is made in respect of it by the county council, and whether he holds any other appointment or carries on any other occupation." This return has now been issued as a Parliamentary paper and it displays several of the pieces which form the curious mosaic that may be collectively described as our system (or want of system) of rural sanitation. It tells us that the appointments in question are made by the councils of 659 rural districts but that, on account of combinations and of divisions of districts and of cases in which more than one appointment is held by a single person, this number does not coincide with the number of officials. For the 659 rural districts there are 682 appointments of medical officers of health and 739 appointments of inspectors of nuisances. There are 30 combinations under the Public Health Act comprising rural districts for the appointment of a medical officer of health, and two comprising a rural district for the appointment of an inspector of nuisances. There are cases in which, without formal combination, officers hold more than one appointment, and others in which the officer for a formal combination holds additional separate appointments. In this way 64 medical officers of health act for 237 rural districts and one inspector of nuisances acts for two rural districts. When the qualifications and conditions of office of a medical officer or inspector are in accordance with the regulations of the Local Government Board, the county council is required to repay to the district council one-half of the officer's salary. Under this provision repayment is allowed in respect of 645 of the 682 appointments of medical officer of health for rural districts, and in respect of 656 of the 739 appointments of inspector of nuisances, or in 94·5 per cent. of the former and 89 per cent. of the latter. In four single rural districts the medical officers of health give their whole time to the duties of the office, and in 23 combined districts they do the same, either strictly, or in combination with other work of a public character. These 23 cases comprise 127 rural districts, but, with one exception, they also include urban districts. There are but 98 cases in which the inspector of nuisances gives his whole time to his duties. The return further shows that in 599 instances, including combinations, the medical officer of health holds some other public appointment, and that in 504 he engages in other work, usually in private practice. Among the inspectors of nuisances there are 597 instances in which the officer has other appointments, such as surveyor of highways, or building surveyor, under the same or some other council, and 140 in which he follows some private occupation.

The arrangements thus described in numerical outline work practically much as might be expected and in the manner only too well known to most of our readers. There is, as a rule, little or no recognition among rural councillors of the moral obligations of their official position, and WALPOLE'S maxim, *Quieta non movere*, expresses, also as a rule, their highest conception of their duties. They regard their health officers in most cases as our grandparents are said to have regarded children—that is to say, as creatures that should be seen and not heard. The councillors are usually men holding respectable business positions in the district, tradesmen or farmers, or in some similar station, able to read their favourite newspaper and to re-echo its views on local or general politics, but almost as ignorant as their own cattle with regard to the protection of the public health, or with regard to the public importance of insanitary conditions. They are slenderly endowed with imagination and are absolutely unable to realise the consequences likely to follow from leaving a case of infectious disease in one of a group of overcrowded and undrained cottages. They are sensitive to expenditure, especially to expenditure the objects of which they are unable to appreciate or to understand; and they have a deeply-rooted conviction that it is unneighbourly to devote too much consideration to the dunghills and other appliances of their own congeners in the vicinity. They have never seen a typhoid bacillus which they would suppose to be something visible and tangible, like a pigeon or a sparrow. They have never seen it go into the water of the village stream, they have never seen it emerge, and they have no assured belief in its existence. They individually would not like to be put to expense for the sake of rendering any cottages belonging to them fit for human habitation, and they wish to extend to other proprietors, and especially to their colleagues on the council, the same indulgence that they would expect to receive themselves. They are very tolerant of the medical officer of health so long as he meets them with a pleasant smile and keeps his duties as much as possible in the background. If he be not satisfied with this position and displays too much consciousness of the responsibilities of his office, he will receive a friendly private intimation that he had better hold his tongue, and if this be disregarded he will find that his practice suffers and that his re-election at the expiration of his term will be more than doubtful. As for the inspector of nuisances, the best way to hinder him from being meddlesome is to give him some more profitable occupation, and he is therefore permitted or encouraged to undertake other duties. We observe one case in which the inspector for two districts in adjoining counties, respectively of 95,873 and of 35,760 acres, and with populations of 9950 and 5803, being paid £55 a year for one of them and £30 for the other, but with no contribution from the county council in either case, is at the same time a practising veterinary surgeon and she is very much improved and has not passed any mucus in the stools for 20 months She is always constipated and hard scybalous masses are frequently present, the bowels only acting after the administration of an aperient. Abdominal massage has been performed for half an hour daily for two months and an abdominal belt is worn.

CASE 3. The patient was a married woman, aged 68 years She had always suffered with dyspepsia and constipation. Some years ago she had a fissure ani followed by hypertrophy of the sphincter ani. During an attack of influenza two and a half years ago she became more constipated and had much abdominal pain, which was colicky in nature, and was followed by the passage of much glairy and gelatinous mucus. This attack passed off in a few days after the administration of castor oil, and enemata of soap and water. Nearly two years ago she had a fæcal accumulation, almost amounting to intestinal obstruction This passed off in a week with enemata of soap and water to which half an ounce of turpentine was added, and oleum ricini was given by the mouth. Later the pains in the abdomen increased and more mucus was passed in the stools. The mucus was in shreds and also in masses resembling frog's spawn. The administration of castor oil and enemata was continued for some months She is now much improved, is still taking castor oil every other day, and she has not passed mucus for more than one year.

CASE 4.—The patient was a married man, aged 60 years. He always had been constipated and markedly neurotic. Nearly two years ago, while straining at a stool, he fainted, and it was then noticed that there was paresis of the muscles of the left side of the face, the left arm, and the left leg The muscular power returned in a few days. One year ago he had a similar attack and the muscular power again returned in a few days. Hæmorrhoids developed ten months ago which at times bled profusely One and a half years ago he had pains, dull and aching in character, all over the abdomen, and once or twice during the 24 hours attacks of sharp colicky pain. The stools at this time consisted of hard fæces, much mucus (in shreds and occasionally in hyaline jelly like masses), and blood, which apparently came from the hæmorrhoidal veins The passage of mucus continued for one week. The patient has much improved under the administration of castor oil, which he still continues to take each morning, and he has not passed mucus for more than one year.

CASE 5.—The patient was a single man, aged 34 years. He had had enteric fever six years ago and rheumatic fever four years ago. The bowels acted regularly as a rule but occasionally he had attacks of diarrhœa. He had attacks of pain at intervals of two months, which was dull and aching in character, over the whole of the abdomen, and occasionally sharp pains. These attacks of pain usually lasted two weeks. The pain made him sweat and when the attacks came on he suffered from vomiting after meals and constipation. He had never had hæmatemesis or melæna. There was tenderness over the epigastric region and the colon could easily be felt throughout its whole length. He passed much mucus in the urine and also some by the bowel during the attacks. The patient was discharged from the hospital much improved, the treatment being dietetic and aperient, combined with copious enemata of sodium bicarbonate in water every night and later of protargol half a drachm to two pints of water.

CASE 6.—The patient was a woman, aged 39 years. She had suffered for the last two years with indigestion, flatulence, and constipation, and she could not walk far. She had had violent pains in the region of the stomach, which had no relation to food, but were worse when she was run down. There were also aching pains and tenderness all over the abdomen. An examination revealed gurgling and splashing sounds along the whole course of the colon. There was no definite tenderness over the sigmoid. Glairy and sticky mucus was passed in the stools. The patient was discharged much better after treatment, which consisted of aperient medicines, irrigation of the bowel with saline solution every morning, and soap-and water enemata every night, which later were changed to enemata of olive oil Swedish massage was applied to the abdomen every day.

CASE 7.—The patient was a woman, aged 35 years. Two years ago she had an operation for appendicitis and a growth of the inside One year and three months ago nephrorrhaphy was performed on the right kidney. Ever since the second operation she had had pains in the abdomen, which were not particularly worse after food but were worse on exertion. She had a poor appetite and the bowels acted regularly There was tenderness over the region of the right ovary but no uterine or pelvic trouble. There was general enteroptosis and much mucus in the stools. The pain still continued With regard to her present condition, there was not much improvement with regard to the pain on discharge from the hospital, but the mucus in the stools became very much less. The treatment consisted of aperient medicines and hot fomentations to the abdomen.

CASE 8.—The patient was a female, aged 38 years. She had always been subject to fits and had suffered from nervous debility all her life The bowels were very irregular, generally constipated She had occasionally passed bright blood in her stools. She had been ill, on and off, for years For eight years she had had burning pains in the right side of her abdomen with frequent intervals of freedom from pain. The pains had been worse during the last three months. She had pains also at the bottom of the back half an hour after food. She suffered a great deal from sick headaches, which lasted 24 hours, about once a fortnight, but she never vomited at other times. The tongue was coated and the teeth were carious. She passed much mucus in the stools like membranes On examination tenderness was marked on pressure over the stomach and the transverse and descending colon. The sigmoid felt woolly under the fingers. She was much improved under treatment with oleum ricini, saline enemata twice a day, hot fomentations to the abdomen, and general massage for half an hour daily.

CASE 9.—The patient was a female, aged 27 years. She had been quite well till ten years ago The attacks then began She had one interval of freedom from pain of four years' duration. She was in the London Hospital for the same complaint two years ago She had been ill for seven weeks with pains in the stomach, which were sometimes of a colicky nature, and she also felt a constant aching pain in the abdomen. The bowels were rather constipated The pain came on when she was run down and there might be intervals of freedom from pain for several weeks She passed much mucus in her stools like membranes and there was also a large quantity of mucus passed in the urine On examination there was much tenderness over the whole of the colon, and especially over the cæcum She was now greatly improved There was no mucus in her stools on her discharge from the London Hospital. The treatment consisted of oleum ricini, hot fomentations to the abdomen, saline enemata daily, which were later changed to half pint rectal injections of protargol ¼ per cent., and general massage for half an hour night and morning

CASE 10.—The patient was a female, aged 35 years. She had never had a similar attack before but had suffered from measles, tonsillitis twice, and anæmia eight years ago The bowels were always very constipated and she had been in the habit of taking aperient medicines freely. There had been slight wasting (three pounds in eight months). She had been ill on and off for 15 months with pain in the epigastrium, radiating to the back, about half an hour after meals, and especially after dinner. The pains were relieved by pressure. The appetite was poor and she vomited after a heavy meal, on an average about once a month. On examination the abdomen was rigid and splashing sounds were elicited in the umbilical region. The teeth were carious and the tongue was clean. Much mucus was passed in the stools in membranous casts and calcareous deposits were noticed occasionally. She improved greatly under treatment with aperient medicines, soap-and water enemata every morning, and olive oil enemata every night

CASE 11.—The patient was a married woman, aged 28 years She had one child, eight years old. She had had two miscarriages, the last being five years ago She had had pain in the rectum since the last miscarriage. The pains were like labour pains and were increased by walking or sitting down She passed mucus in the stools in shreds 12 months ago On examination tenderness was found over the ascending colon and the sigmoid felt like a cord. On sigmoidoscopic examination the mucous membrane was red, polypoid, and apparently thickened. She had been curetted twice for foul vaginal discharge. She was operated on on June 24th, 1905 (ileocolostomy). (A lateral anastomosis was made between the ileum and the middle portion of the sigmoid.) The passage of mucous and the pains ceased for a time. She was readmitted on August 23rd, 1905, passing much mucus in the stools which resembled membranes. She also suffered with severe abdominal pains The bowels never acted without aperients She was discharged much relieved after treatment with aperients and saline injections every morning which later were changed to injections of protargol ½ per cent.

CASE 12.—The patient was a female, aged 23 years. She had had two similar attacks before, the first three years ago and the second 12 months ago. The bowels acted regularly as a rule but when the attacks came on she was constipated. She was admitted to the London Hospital with pains in the stomach and vomiting The vomiting always began directly after meals Two months ago she vomited about an egg-cupful of blood and since then occasional streaks. The pain was felt in the stomach and often in the lower part of the abdomen, and through to the back. She also had an aching pain in the abdomen. The pains were not relieved by vomiting and they bore no relation to her meals The stools contained much mucus and residue of cellulose. An examination revealed gurgling in the transverse and descending colon. There were no enteroptosis and no anæmia. The teeth were good. The tongue was large, flabby, and coated. She improved under treatment with aperient medicines, and saline injections every morning, and soap-and water enemata every night.

CASE 13.—The patient was a married man, aged 40 years. He had been ill on and off for eight years. He had had several slight attacks, passing a little blood and much mucus in his stools, accompanied by colicky pains in the abdomen. He had always suffered from indigestion, flatulence, and constipation. He had been having attacks about every two months of severe colicky pains in the abdomen, and the stools contained much gelatinous mucus On examination the abdomen was somewhat distended with flatulence. The stomach was dilated. The liver and spleen were not enlarged perceptibly. There was definite tenderness over the sigmoid, which could easily be felt. The tongue was slightly coated with a light brown fur. The patient was very much improved after taking castor oil three times a day.

CASE 14.—The patient was a man, aged 40 years, an ex soldier. In Egypt in 1885 he had a very slight attack of dysentery and no relapse. His bowels were constipated as a rule. He was seized with pain in the abdomen and diarrhœa, with nausea The pain was constant in the lower part of the abdomen and was of such severity that he sweated very much. The stools contained much mucus and a little blood. On examination the descending colon and sigmoid were found to contain hard fæces and hard fæces could be felt per rectum. The temperature was normal. He improved very much under treatment, and on his discharge there was no mucus in the stools and he had a good appetite He was treated with aperient medicines

CASE 15.—The patient was a married woman, aged 23 years At the age of 13 years she suffered from chorea, which was followed by mitral regurgitation Five years ago she had an ulcerated throat, a miscarriage, and dysentery, and she had never been quite well since. A fortnight before admission she had diarrhœa (from 10 to 13 stools in 24 hours) She had pains in her stomach and in the left side and lower part of the abdomen. She occasionally vomited with relief of the pain for a time The stools contained a little blood and much mucus in shreds, with little fæcal material. An examination of the abdomen revealed no abnormality and nothing abnormal was discovered on rectal examination. The uterus was small and retroverted and the left ovary was tender On her discharge from the London Hospital she was much relieved The treatment consisted of oleum ricini daily, followed by bismuth subnitrate, saline injections every morning, followed by olive oil, four ounces, and water to ten ounces

CASE 16.—The patient was a single woman, aged 19 years. She had always suffered with bad indigestion, which became worse four months ago She had always been a nervous girl, suffering with headaches and peculiar sensations in the feet. At the age of eight years she had round worms At the age of ten years she had diarrhœa for four months in the summer and passed blood in her stools From the age of 10 to 15 years she had bilious attacks with vomiting At the age of 15 years she had enteric fever and she had been unwell ever since with constipation. One year ago she had gastric ulcer. The catamenia only occurred once in three or four months, she had severe pain for one or two days before, and for three or four days after, the period had commenced The pain was not relieved by lying down nor was it increased by walking She was ill for four months before admission to the London Hospital suffering with a poor appetite, constipation, and pains in the abdomen of a colicky nature preceding defæcation. The stools consisted of hard fæces and much mucus which resembled pieces of skin. On examination the tongue was dry and coated. There was superficial tenderness over the whole of the left side of the abdomen while this condition is much more common in women than in men. His observations confirm the fact previously known that the passage of tubular casts may occur in association with actual disease of the colon, notably catarrhal conditions and cancer; and they suggest that such local lesions are probably more common than is supposed, but they can hardly be regarded as conclusively demonstrating that a condition of mucous colic does not exist apart from obvious local lesions, especially in view of the fact that in some fatal cases such lesions have not been found. The use of the sigmoidoscope in the investigation of these cases marks a distinct advance and will doubtless supplement the little that is at present known of their pathology if it is systematically used, and the results obtained correlated with the careful records of the necropsies of fatal cases of which but few are as yet on record. Indeed, the disease, apart from complications, appears to be but rarely fatal, which, as NOTHNAGEL suggests, is the reason of the differences of opinion existing. At the present time NOTHNAGEL's classification of these cases into three groups seems best to conform to the facts known—viz., a group in which the abnormal formation of mucus is a neurosis of secretion without inflammatory changes; a second group with catarrhal changes in the mucous membrane, the mucus production being here also regarded as a superadded neurosis of the secretion processes; and a third group in which there is a chronic catarrh of ordinary character with occasional attacks of membranous diarrhœa, instead of continuous mucous secretion as in the second group. Dr. HARRISSON's paper deals fully with the etiology of the disease and he touches upon the association existing between mucous colitis and appendicitis, about which there is considerable difference of opinion. By some appendicitis is regarded as a cause of the colitis, and removal of the appendix[1] has been suggested as one form of treatment; by others both conditions are regarded as the result of a common cause, while yet others, among them Dr. H. A. CALEY, regard the colitis as an important antecedent of appendicitis. Dr. CALEY[2] quotes DE LANGENHAGEN who saw among 1200 cases of membranous colitis only 16 cases of appendicitis, in 14 of whom the appendix had been removed without relief of the symptoms of colitis, while Dr. BOTTENTUIT has seen 22 cases of membranous colitis in which the symptoms were not materially relieved after excision of the appendix. A variety of conditions have been regarded as predisposing to membranous colitis; among these we may mention the "arthritic diathesis" which DE LANGENHAGEN regards as the basis of every case. The same observer insists on the frequent association of enteroptosis with membranous colitis. Dr. HALE WHITE attaches more importance to disorder of the female generative organs as an antecedent; no less than 21 of his 51 female patients suffering from membranous colitis had a history of some disturbance of these organs. In this connexion it is of interest to notice that membranous dysmenorrhœa has been observed in association with membranous colitis. Influenza is by some regarded as a cause of the condition; at any rate, colitis may be much aggravated by an intercurrent attack of that disease. With regard to the almost invariable association of chronic constipation nearly all observers are in agreement. The very frequent association of marked neurasthenic symptoms with the disease has led to a neuropathic theory as to its origin, but it is more probable that the neurasthenia is the result of the colitis, and this view is supported by the observations of DE LANGENHAGEN who found that in 304 cases with neurasthenic symptoms these had preceded the intestinal symptoms in only 16 cases.

We need only refer to Dr. HARRISSON'S paper for an exhaustive account of the symptomatology of the disease, and he deals thoroughly with its diagnosis and prognosis. He rightly lays important stress on the necessity of preventing fæcal accumulation in the large intestine as the first step in the treatment of the disease. This may be attempted by aperients, of which the best appears to be castor oil, given early in the morning and continued daily even for some weeks. Magnesium sulphate or calomel has been given where castor oil cannot be taken. Either as an adjunct to this treatment or as a substitute for it, systematic washing out of the colon with warm water or with tepid saline solution, even to the extent of several pints, is most useful. Some cases derive great benefit from treatment at certain continental spas where systematic irrigation is practised, notably at Plombières, Royat, Chatel-Guyon, and Homburg, the natural waters being used for purposes of irrigation. Similar treatment has been carried out at Harrogate in this country.[3]

Dr. HARRISSON concludes his paper by a brief description of the various attempts that have been made to give relief to some of the more chronic and intractable cases by surgical measures.[4] So long ago as 1880 HAHN in Germany operated on a case of ulcerative recto-colitis by colotomy successfully. During the next 15 years a few similar operations were performed by different surgeons with some success. In 1895 Mr. C. H. GOLDING-BIRD operated on a case of membranous colitis for Dr. HALE WHITE, and from that time similar measures have been frequently carried out. The chief operations performed have been colostomy of either the right or left side, with or without irrigation of the bowel, and appendicostomy. Short circuiting has also been done in some cases. Many successful results have now been recorded by one or other of these methods. Dr. HALE WHITE, who has followed the history of some of these patients, recommends that the fistula should be kept open for a year in severe cases. He is also of opinion that operation should but rarely be performed. The choice of cases for operation certainly requires great care and judgment. It should not be done in mild cases, or until careful trial of medicinal measures with a course of treatment by systematic irrigation at some suitable spa has failed, or in very chronic cases with marked neurotic symptoms.

◆

Inquests and Preliminary Inquiries.

AT a recent inquest at Battersea Mr. TROUTBECK, the coroner for Westminster, made some observations with regard to the unsatisfactory nature of the law relating to inquests which have been widely reported and commented upon and which possess considerable medical interest. The principal point to which he called attention is not a new one, for his was no obvious discharge from the nose or ears, and the medical man who had been in attendance said that he was unaware of any. There was no obvious enlargement of the glands to be felt anywhere. On opening the skull and examining the brain a few petechiæ and some slight hyperæmia were observed in connexion with the cerebral meninges and a few of the posterior convolutions were slightly adherent. Prior to opening the skull I had removed under aseptic conditions by lumbar puncture about two cubic centimetres of cerebro-spinal fluid which was observed to be blood-stained and slightly turbid. I inoculated with this fluid two sterile blood-agar tubes and two ordinary broth tubes, which I subsequently conveyed to the laboratory for further investigation. On opening the abdomen the omentum was observed to have a dirty, degenerated appearance. The intestines were empty and their walls were dotted with numerous petechiæ; otherwise they appeared normal. The spleen was slightly enlarged, very dark, and congested and firm. The liver was not removed from the body but it appeared to be healthy. A similar remark applies to the lungs. The pericardial sac contained a slight excess of fluid. The heart was removed and found to exhibit some signs of fatty degeneration. Its walls showed also a few petechiæ. On slitting open the aorta some well-marked vegetations were found on the free edges of the aortic cusps. The mitral valves were found to be thickly coated with similar deposits. With the aid of a sterile swab I inoculated another blood-agar tube from the site of these vegetations. Each kidney was found to be extremely hæmorrhagic on the surface, under the capsule, which stripped fairly easily. The suprarenal bodies were looked for but were not recognised. The post-mortem appearances plainly indicated a septicæmic or embolic condition, the cardiac lesions being characteristic of malignant endocarditis.

[4] A useful *résumé* is given in a paper by Ingersoll Olmsted in the Brit. Med. Jour., Nov. 10th, 1906, p. 1277.

The question naturally arose, where was the primary infecting focus? and what was its nature? There being nothing obvious I felt certain that there must have been some sore-throat or aural antecedence which had not been deemed of any consequence, and on cross-examining the parents I ascertained that the child had had earache and discharge from the ear about three weeks previously. The ear had apparently ceased discharging before the medical attendant was called in and had been so little thought of that the matter had not been even mentioned to him. The parents were certain that the child had never complained of sore-throat, though in order for a middle-ear to become infected it almost necessarily follows that in the absence of an external lesion infection must have been conveyed in the first place from the naso-pharynx. After incubation at 37° C for 16 hours I obtained a copious growth of a pure culture of Klebs-Löffler diphtheria bacillus from the cerebro-spinal fluid and almost a pure culture of the same organism from the heart swab. On account of the naked-eye appearances at the post-mortem examination the attending practitioner had naturally certified the cause of death as malignant endocarditis, but the subsequent bacteriological analysis revealed the interesting fact that the infecting organism was the diphtheria bacillus.

One of the chief points of interest is that the case was reported to me after death because of the suspicious resemblance of the later symptoms to cerebro-spinal fever, as shown by the retracted head, the strabismus, headache, photophobia, raised temperature, and petechial rash. Bacteriological investigation clearly showed that the diphtheria bacillus had certainly invaded the central nervous system and embolic plugs laden with diphtheria bacilli would be sufficient to account for these symptoms. As the necropsy was conducted in a small room in a cottage the vertebral column was not opened up. Perhaps this was not altogether a disadvantage, for it lessened the possibilities of contamination of the cerebro-spinal fluid. No evidence of any diphtheritic membrane was seen elsewhere. The attending practitioner had examined the throat with no result during life.

The case here reported might easily have been certified without post-mortem examination as a death due to cerebro-spinal meningitis. Even after post-mortem examination it was certified as death from malignant endocarditis but subsequent bacteriological investigation seems to indicate that death was due to a diphtheritic septicæmia. The case recorded once again suggests that isolated cases of death preceded by symptoms of cerebro-spinal meningitis should not be attributed to epidemic cerebro-spinal fever without adequate bacteriological proof. To justify the diagnosis of epidemic cerebro-spinal fever it would appear to be quite necessary that the presence of the diplococcus intracellularis of Weichselbaum should be demonstrated.

It is greatly to be regretted that the circumstances of the necropsy in the case I have recorded rendered it impossible to make a full examination of the middle and internal ear and of the naso-pharynx. These important structures, the porchway or entrance for probably the majority of infective bacteria, are, as a rule, neglected in ordinary post-mortem examinations. Their importance should, I venture to submit, form a pretext for invariable examination in all cases of an infective or doubtful nature.

The finding of the diphtheria bacillus in the cerebro-spinal fluid of a case dying with symptoms of cerebro-spinal meningitis naturally suggests a possible explanation why diphtheria antitoxin has been found of service in some cases of cerebro-spinal meningitis, though I am quite prepared to believe that such treatment might have beneficial results quite irrespective of the diphtheria bacillus and in the actual presence of the diplococcus intracellularis.

Another interesting observation to call to mind is the diphtheroid bacillary infection hypothesis of W. Ford Robertson, G. D. McRae, and J. Jeffrey in connexion with general paralysis and tabes. The existence of a true diphtheria bacillus in pure culture in the cerebro-spinal fluid is in itself an interesting and important fact. Its presence as the predominant organism in endocardial vegetations is also both interesting and suggestive. Its low virulence for the guinea-pig, as tested by experiment on two guinea-pigs by Dr. W. Bulloch, is equally interesting and affords pabulum for reflection. I have to thank Dr. Bulloch for kindly conducting the animal experiments in connexion with this organism and I am very greatly indebted to him for the weight of his authority in corroborating its identity as a true diphtheria bacillus.

It seems worth while to set down in detail the results of bacteriological investigation.

1. The organism was isolated in pure culture on blood agar direct from the blood-stained cerebro spinal fluid of a child who had died with marked cerebro-spinal symptoms after a previously ill-defined illness.

2. After 16 hours' incubation at 37° C. very characteristic colonies of the bacillus diphtheriæ were found on the blood agar. The appearance of the colonies at once suggested bacillus diphtheriæ. This was forthwith confirmed by:—

3. *Microscopic appearances.*—The bacillus was Gram-positive. Films stained by Löffler's blue, by Neisser's and by Gram's methods exhibited large long diphtheria bacilli conforming to Westbrook's types A and C, Neisser's and Babes-Ernst bodies being particularly well marked.

4. *Cultural characters.*—(1) The organism was aerobic and facultative anaerobic; (2) it grew on gelatin at room temperature without liquefaction; (3) it produced marked acid in glucose broth and in milk; (4) it produced slight acid in saccharose broth; and (5) it did not clot milk.

5. *Animal experiment.*—For details of its comparative pathogenicity I am entirely indebted to the kindness of Dr. Bulloch who reports as follows: "I have carefully examined the culture you sent and have no doubt that it is a genuine diphtheria bacillus of slight virulence. Morphologically it is the long variety of Klebs-Löffler with marked Neisser's granules, Gram +. Marked acid production in glucose broth. A culture (in broth) 24 hours old was injected into two guinea-pigs in doses of 1 c.c. and 5 c.c. respectively. In both cases marked infiltration occurred with loss of weight. The 1 c.c. guinea-pig was killed in 24 hours and the infiltration at the point of inoculation was a sanguinolent œdema. No bacilli, however, were seen in smears and a culture was recovered with some difficulty. The suprarenal bodies (usually much congested) were not affected. The other guinea-pig four days after inoculation showed slight infiltration only."

I might add that this bacillus even in the original culture when only 16 hours old exhibited unusually large and grotesque forms which appeared to me to favour the idea that in the life-history of the bacillus it may under certain conditions assume a hyphomycetic form.

There can, I think, be but little doubt that the history of the case I have recorded may be written as follows. The child in the first instance suffered from a mild form of diphtheria which was untreated, and the bacilli found their way *viâ* the Eustachian tube to the middle ear, giving rise to otitis media. Thence by way of the blood or lymph bacilli were carried to the heart, there setting up endocarditis and

"Ne quid nimis."

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

WE have received the following statement for publication from the Board of Education: "The Board of Education have decided to establish a medical department to advise and assist them in the discharge of the new duties imposed on the Board by Section 13 of the Education (Administrative Provisions) Act in regard to the Medical Inspection of School Children which local education authorities are required by that Act to carry out in England and Wales. The chief duties of the Board in this direction will consist in advising and supervising local education authorities as to the manner and degree in which those authorities carry out this medical inspection; in giving such directions as may be necessary regarding the frequency and method of such inspection in particular areas; and in considering and sanctioning such arrangements as may be proposed under the Act by individual authorities for attending to the health and physical condition of the children. The Board will also collect and collate the records and reports made by the authorities in the process of carrying out the new duties imposed by the Act, and will issue an official annual report on the subject. The organisation and *personnel* of the Board's medical department are not yet fully determined, but in view of the varied factors and influences which are concerned, directly or indirectly, with the health and physical condition of the children of the nation, it has been decided by the Board to establish the department on a broad basis of public health, and so organise its work as not only to allow of reasonable freedom for local authorities as to particular methods, consistently with securing an adequate degree of uniformity in the presentation of results for comparative purposes, but also to use as far as practicable the means and methods of sanitary administration already existing, and to develop and supplement these as may be found best for the increased requirements, rather than to supplant them or to bring new competing agencies into existence where this may be avoided. As a first step the President has appointed Mr. George Newman, M.D., F.R.S. Edin., D.P.H. Camb., as chief medical officer of the Board. Dr. Newman has been medical officer of health of the metropolitan borough of Finsbury since 1900. He is also lecturer on public health and sanitary administration in St. Bartholomew's Hospital (University of London), and has had the advantage of provincial experience as consulting medical officer to the county council of Bedfordshire. He has published various works and official reports upon matters of State medicine, both of a general and special character, including the control of the milk-supply, infant mortality and its prevention, infectious diseases and sanitation in schools, food poisoning, housing, water-supplies, and the physical condition of the people. Dr. Alfred Eichholz, who has for nine years been on the Board's staff as medical inspector of schools, and, in addition to his special work in the schools for blind, for deaf, for epileptic and for defective children, has had close experience of the medical, hygienic, and sanitary aspects of elementary schools generally, and of recent investigations into the national physique as illustrated thereby, will also be appointed to the medical department; and further appointments will be made in due course. The Board intend in the autumn to issue a circular to local education authorities regarding their new duties in the matter of medical inspection of school children." The Board of Education cannot expect that at least one of the appointments thus announced will escape criticism. Dr. Newman's excellent public work has not necessarily given him much first-hand experience of the kind that he will require in the discharge of his important and delicate duties.

THE INTERNATIONAL CONGRESS OF "GOUTTES DE LAIT."

THE Second International Congress of "Gouttes de Lait" was held in Brussels from Sept. 12th to 16th. The Congress was attended by over 600 delegates, including some 40 representatives from Great Britain. At the first Congress of Gouttes de Lait, which was held in Paris in 1905, the discussions were almost exclusively confined to the work of the "Goutte de Lait," an institution which is represented in this country by the infants' milk depôts that have been established by several of our municipalities. The scope of the Brussels Congress, however, was much wider, and included the whole question of the prevention of infantile mortality. It was decided that the scope of the future congresses should be similarly enlarged, and that the next congress, which is to be held in 1910 in Berlin, should be called the International Congress for the Protection of Infant Life. An account of the Brussels Congress will appear in a future issue.

SCIENCE "IN EXCELSIS."

"THE highest research station in the world" (writes an Italian correspondent) "was on the 27th ult. thrown open to the nature student of all nationalities on the Colle d'Olen (Monte Rosa) 3000 metres above sea level. The ceremony was honoured by the presence of the Queen Dowager (Margherita of Savoy) and the spokesman of the day was Dr. Luigi Pagliani, professor of hygiene in the University of Turin, who, in the presence of an audience representing the combined science of the continent, unveiled the inaugural tablet in the name of the King of Italy and declared duly open the Istituto Scientifico Internazionale, which bears the title of its 'hero and eponymus' Angelo Mosso. Professor Pagliani's eloquent discourse was followed by that of Professor Sarasin, representing Switzerland, conveying the thanks of non-Italian nature students for the hospitality accorded them by the youngest of the European Powers; then came Professor Mosso himself, who felt in the inaugura- tion of the istituto that he had put the appropriate crown on a long career devoted to Alpine exploration and research; and lastly spoke the Commendatore Grober, giving voice to the special acknowledgments of Germany. Thereafter the Queen made her progress through the rooms of the istituto, admiring the equipment of the various labora- tories and passing words of commendation on the other appointments for the nature students in residence. Descend- ing on foot (as became a veteran Alpine pedestrian) the Queen bade farewell on the Piazzale del Colle d'Olen to the dis- tinguished company who, subsequently, to the number of 50, sat down to a banquet prepared for them in the Guglielmina Inn, the place of entertainment nearest to the istituto. Again the occasion inspired the orators of the party, some of whom dwelt with just and generous insistence on the humble collaborators of the institute—the masons, the carpenters, the whole *personnel* of the building and its equipment—who, after years of toil, amid storm and inclemencies truly Alpine, had seen their reward in the ceremony of the day. 'Science and labour,' said the Commendatore Grober, 'had worked loyally together in a spirit of the best augury for the future of humanity.' Then the company broke up, some to descend to the sub-Alpine plane, others to prepare for an ascent of Monte Rosa whose crest looked inviting—not to say defiant—to the more adventurous.

with the exception of the native foremen who, sharing food with the whites, obtained a portion of the meat that was left. He, attributing the cause to the absence of meat, fresh or otherwise, pointed out that the Damaras are in the habit of eating to engorgement of the putrid carcasses of hunted animals without apparent harm and certainly without scurvy. Dr. Sinclair suggests that the transference of inland natives to the more rigorous climate of the coast, the conditions of the huts, and the heavy work in which they were engaged may have been accessory causes to the outbreak.

It will be seen from the above that there is weighty evidence upon both sides and in support of both theories.

Roberts in his text-book gives the following three possible causes of scurvy: (1) the absence of vegetables or their ingredients, probably the malates and lactates; (2) the presence of toxic material in the food; and (3) the presence of a specific organism in the food or introduced in some other way. In support of the first two theories evidence has been given above; in support of the last there seems little to be said except the parallel between scurvy and other diseases known to be produced by a specific organism.

In the case reported below there is nothing in the history of the patient or in the treatment which she received to lend support to either the first or the third augument; but the presence of a septic focus around the rectum whence absorption takes place readily and freely suggests the possibility of the introduction of toxic material into the circulation. Whether such poisonous matter produced scorbutic symptoms or not it is difficult to determine, but since the other factors usually associated with an outbreak of scurvy were absent it is not unreasonable to suppose that its presence may have been the determining element. The reaction of the patient to treatment also is instructive, for she responded quickly to ordinary antiscorbutic measures. Apart from local treatment for the hæmorrhage, the patient was given the following: four half-drachm doses of calcium chloride in the course of 48 hours and a subcutaneous injection of a hundredth of a grain of ergotinine citrate, whilst two lemons and quantities of green vegetables were added to her diet. Under this treatment she speedily recovered in the manner detailed below. With the constitutional improvement the condition of her wound, which previously had been unsatisfactory and sluggish, underwent a corresponding change for the better. The use of calcium chloride was on account of the bleeding, and although unfortunately the alkaloid ergotinine was used as well, it is reasonable to accredit the rapid cessation of hæmorrhage partly at least to the use of the calcium salt. This is of interest because of the doctrine put forward by Sir A. E. Wright that the prominent feature in the pathology of scurvy is a reduced alkalinity of the blood, together with a reduced coagulability which allows of the spontaneous outpourings of that fluid. This view of the pathology of scurvy dovetails with the theory that its cause is absence of vegetable salts from the food; for the citrates, tartrates, and malates of herbaceous food become changed into carbonates in the blood. As, however, the food which the patient had been in the habit of taking does not seem to have been in any way scorbutic, the suggestion that absorption from a septic focus was the initiating cause receives support. The history and progress of the case are as follows.

The patient was admitted to St. Mark's Hospital on April 6th, 1907, with an unhealed wound after two operations for fistula in ano which had left her without sphincteric control. There was also some prolapse of mucous membrane. She was a spare woman of pallid aspect, showing evidence of loss of weight and prolonged suffering, but exhibiting no signs of disease other than the rectal mischief. She gave a history of typhoid fever ten years previously and some chronic bronchitis. Her present trouble began in September, 1904, with a fistula of moderate size. She was—during 1905 and 1906—treated at St. Bartholomew's Hospital, being admitted into the in-patient department during the October of each year. During the whole of this time there was a copious purulent discharge which progressively increased. In February, 1907, she came as an out-patient to St. Mark's Hospital and in April she was admitted as an in-patient. Her wound then was an extensive gap situated dorsally and to the left of the anus, involving the mucous membrane of about from half an inch to an inch of the rectum. Owing to the separation of the cut surfaces of the sphincter ani and to the extensive fibrosis around, there was no power of that muscle and therefore no control. The surface of the wound was unhealthy in appearance, having that peculiar aspect known as "callous." There was an abundant discharge of thin, offensive pus which had produced an irritable condition of the surrounding skin. On April 9th, 1907, a branch tract of the fistula was opened up, preparatory to an attempt to diminish the gap and restore the continuity of the sphincter. 19 days later such an effort was made, the wound being freshened and brought together with sutures. Some suppuration occurred necessitating the removal of three stitches, the wound then being a little smaller than before. For a fortnight following the operation the temperature ranged between normal and 101° F., then for a week it remained within a degree of 98·4; during the whole of which three weeks the wound continued to discharge freely, its surface retaining the sluggish appearance. The temperature now became irregular, ranging through two degrees; at the same time the patient assumed that inert listless condition commonly seen in typhoid fever. Soreness of the mouth was complained of, and on examination the gums were found to be tender and swollen, the tongue clean, and the pulse 80. The patient was given an alum mouthwash, whilst careful attention was enjoined as regards the cleanliness of the teeth. The temperature now became intermittent, the excursion being 3°. After this condition had lasted for seven days hæmorrhage began from the gums, which soon became profuse. On the following day blood began to flow from the rectal wound, soaking the dressings which were constantly changed. Simultaneously a purpuric rash appeared upon the face, shortly followed by petechiæ of wider distribution. The arms, especially the shoulders, and the legs, especially the buttocks and thighs, were mostly affected, the trunk being almost free from spots. With the onset of the bleeding the temperature became steady; the pulse was weak and irregular and it varied between 90 and 100, whilst the respirations were 28 per minute. In the course of 24 hours four half-drachm doses of calcium chloride were given, a hazeline mouthwash was used frequently, and at the onset of bleeding a hypodermic injection of ergotinine citrate was administered. At the point of entrance of the needle a hæmatoma of the size of half a walnut was produced. After the hæmorrhage had continued for three days it gradually ceased. The patient was then given an alum mouthwash and a mixture containing iron and quinine, whilst two lemons and extra vegetables were added to her daily diet. There was no return of hæmorrhage, the temperature and pulse became satisfactory, the mouth resumed its normal condition, and the patient's general condition greatly improved; her weight increasing, the mental outlook becoming bright and active, and her pallor less marked. Associated with this improvement there was a corresponding change in the wound, the reparative power of the tissues increasing, and healing being accelerated. Three weeks later the patient was able to go to the seaside, if not cured very considerably improved.

Three points of interest seem to arise out of this case. 1. The occurrence of scurvy in a patient whose food had been the same as customary among people of her class, for on special inquiry she stated that she was in the habit of taking plenty of good and fresh food. Moreover, she had been in hospital a month, where her diet was a plentiful one of milk, beef-tea, custard, jelly, and so on, before the onset of the scorbutic symptoms. 2. The possibility of the retardation of healing seen in certain forms of long-standing "callous" wounds being due to a scorbutic diathesis. 3. The possibility of the long-continued suppuration and mental distress being the cause of this diathesis, a vicious circle thus being produced.

I am indebted to Mr. F. Swinford Edwards, senior surgeon to St. Mark's Hospital, for permission to report this case.

PRELIMINARY NOTE ON A LEUCOCYTOZOON FOUND IN THE BLOOD OF THE RED GROUSE (LAGOPUS SCOTICUS).

BY C. G. SELIGMANN, M.D., M.R.C.P. LOND.,
BACTERIOLOGIST TO THE COMMISSION ON GROUSE DISEASE,
AND
LOUIS W. SAMBON, M.D. NAPLES, F.Z.S.,
LECTURER TO THE LONDON SCHOOL OF TROPICAL MEDICINE.

WHILE examining blood films of a number of grouse sent to Dr. E. A. Wilson, field observer to the Grouse Commission, as birds suffering from grouse disease, a protozoal blood parasite of a genus hitherto unknown in the *Tetraonidæ* was discovered. The bird in which it was seen special work, such as the pathology of the organs of special secretion, are given. A limited number of men are admitted for research work. In the anatomical and physiological laboratories a limited number of men are admitted for advanced work, as, for example, in the anatomy of the nervous system, embryology, and physiology. A similar course is available in physiological chemistry. In all of these the fitness of the applicant is decided by the head of the department.

SULLY PRUDHOMME.

DELICACY of health in childhood or serious illness in later life has often decided the destinies of men of genius. The weakly child often cannot engage in the calling of his father and the strong man, smitten down by prolonged sickness, must perforce content himself by following for the rest of his life the sedentary occupation of the student or writer. It is thus that Sully Prudhomme, trained in the exact sciences and destined at first to the career of an engineer, turned to poetry when a sudden succession of family bereavements and the horrors of the war of 1870 had shattered his nerves and left his sensitive frame a wreck. For 37 years, until his death in his garden at Châtenay on Sept. 7th, Sully Prudhomme, the erewhile man of science, the severely trained mathematician, built up his own poetic reputation and has died, leaving a literary monument, which, as a writer in the *Figaro* points out, is "l'un des plus nobles, en vérité, l'un des plus purement beaux dont s'enorgueillisse l'art français." He attained to fame while at times suffering the anguish caused by slow paralysis, coupled with occasional attacks of meningitis that threatened his life. Strange to say, a life of intermittent torture never once impaired the solid reasonableness of his poetic genius. Delicate and punctilious and truly poetic though his verse undoubtedly is, he remains the poet of reason, of the scientific outlook of modern intellectualism, and illustrates in a forcible degree the truth that between artistic imagination and latter-day science there is no necessary gulf of division. The exact sciences can boast few such types as Prudhomme, though medicine has been adorned indirectly by a Goldsmith, a Keats, and a Bridges.

THE BACTERIOLOGY OF PLASTERS.

IN the *Pharmaceutical Journal* of July 27th Mr. G. Pinchbeck gives the results of an investigation into the bacterial condition of plasters and the results which he has obtained are sufficiently disquieting to merit the attention of the medical profession. Mr. Pinchbeck has made a bacteriological examination of various commercial plasters and protective tissues that had been stored under different conditions. Ordinary adhesive plaster from a package frequently opened contained an average of 22 colonies per square centimetre and a specimen of soap plaster similarly stored contained 20. Adhesive plaster prepared with a rubber basis gave better results, an opened package containing seven colonies per square centimetre and a new unopened package being sterile. Medicated adhesive plasters with a lead, resin, or soap basis were found to be not sterile, chalybeate, belladonna, and cantharides plasters containing respectively 13, 53, and 160 colonies in the same area. But medicated adhesive plasters with a rubber basis gave better results; plasters medicated with capsicum, belladonna, belladonna with aconite, and opium containing respectively 5, 31, 2, and 17 colonies to the square centimetre. These samples, with the exception of the belladonna plaster, were all newly opened and newly opened packets of menthol and oxide of zinc plasters were found to be sterile. An examination of a number of "court plasters" disclosed a worse state of things. A sample of isinglass plaster stored in a tin that had been freely exposed contained 341 colonies to the same area, while samples of "tri-colour" plaster, after being carried in a vest pocket for three months, contained no less than 1420 colonies. This class of plaster is especially rich in bacteria, chiefly owing to the use of isinglass, gelatin, gum arabic, and honey in preparing the basis. These ingredients form excellent culture media and the subsequent exposure of the plasters to a temperature of from 50° to 60° C. serves still further to favour the development of spores. Such plasters are usually carried in a purse or wallet for instant use in case of cuts, but their bacterial impurity is so high that they are a source of positive danger. Mr. Pinchbeck found staphylococcus pyogenes aureus and albus, bacillus pyocyaneus, bacillus murisepticus, streptococcus pyogenes albus, and other organisms in this type of plaster. As regards protective tissues, Mr. Pinchbeck found that unopened packets of gutta-percha tissue were sterile, while an open packet contained five colonies per square centimetre. Goldbeater's skin contained from 24 colonies in an unopened packet to 310 colonies per square centimetre in an opened packet. Goldbeater's skin is prepared from the peritoneal membrane of the cæcum of cattle. It is liable to contain bacteria owing partly to its avidity for water but more particularly to the use of septic membranes or contamination during manufacture. Mr. Pinchbeck has clearly proved the necessity for exercising care in the selection of plasters which from many causes may convey septic infection. He has investigated the various methods available for sterilising plasters and has ascertained that the addition of an antiseptic substance to the plaster is an efficient method of sterilisation. Among the substances suggested are thymol, chlorbutyl alcohol, iodol, beta-naphthol, and methyl salicylate. A rubber basis is effectually sterilised by the addition of 0·4 per cent. of thymol or 0·6 per cent. of methyl salicylate. For "court plasters" Mr. Pinchbeck recommends 1 per cent. of phenol. But he rightly condemns the dangerous practice of moistening such plasters with the tongue before applying them to a cut. The rubber basis, prepared from pure Para rubber, is an ideal plaster medium. It dissolves or mixes with various medicaments, is free from irritating properties, and produces the most adhesive plaster known. The rubber basis is strong, neutral, fairly stable, and waterproof, and is certainly much superior to the various bases employed in making the official plasters. It should always be supplied on reels in order to expose as little of the surface as possible to the atmosphere.

THE CITY OF WESTMINSTER COUNCIL AND THE STREETS UNDER ITS CONTROL.

IN the *Times* of Sept. 17th appears a letter signed by four members of the Savile Club, one of whom is a medical man, referring to the condition of the roadway of Piccadilly in the early hours of Friday morning, Sept. 13th. In it occurs the following passage:—

> The road was being flushed at Hyde Park-corner, but the hill from the St. James's Club to Devonshire House had not been touched and was excessively slippery from the traffic of the previous day and from motor grease. No gravel was to be had and the sandbox opposite the St. James's Club was empty. The horses drawing the heavy market carts had terrible work, one horse in its struggles to get up the hill fell down and died. At times the whole width of *Piccadilly* was blocked by carts unable to get up the hill.

The letter goes on to state that the police say that the same scene occurs almost nightly and that they are *powerless* as the City of Westminster council is *responsible* for the state of the road. We have upon sundry previous occasions called attention to the unsatisfactory way in which the City of Westminster council manages the cleansing and gravelling of the roads under its care (*vide* THE LANCET, Dec. 18th, 1902; Jan. 24th, 1903; and Jan. 5th, 1907). In 1903 the excuse given was that no ballast for gravelling the roads could be procured. Piccadilly has been more or less a chaos since the beginning of July owing to the laying of

These stimuli are referred usually to points on the same side of the body but, for a reason that we cannot consider here, a certain number are referred to the corresponding point on the opposite side. The symptom of false allochiria does not need any special designation other than the general one of alloæsthesia, for its significance and pathogenesis are identical with those of the latter condition. It differs clinically from true allochiria in respect to seven precise features. 1. In alloæsthesia only a certain number of the stimuli are referred to the contralateral side, usually less than 50 per cent. of them; in allochiria the stimuli are invariably referred to the contralateral side. 2. In alloæsthesia the symptom in question is merely an instance of the erroneous localisation that takes place in every direction, so that the error in transverse localisation bears an exact relation to the error in vertical localisation; in allochiria there is no error in localisation apart from the mistake in the side. In alloæsthesia a touch on the inner side of the ankle might be referred to the outer side of the ankle, to any point on the foot or leg, or to the opposite ankle; in allochiria such a touch would invariably be referred to the inner side of the opposite ankle and nowhere else. 3. In alloæsthesia there are disturbances of common sensibility — particularly hypoæsthesia—*which are important factors in bringing about* the erroneous localisation; allochiria bears no relation to any defect of cutaneous sensibility, though such defect may sometimes be present independently. 4. In alloæsthesia there may be hypoæsthesia or paræsthesia but there are never present the peculiar attributes that we shall consider in connexion with allochiria under the name of Phrictopathic Sensation. 5. In alloæsthesia hallucinatory sensations and polyæsthesia frequently occur; in allochiria this is not so. 6. In alloæsthesia there are no corresponding motor manifestations, except perhaps ataxy; in allochiria motor manifestations are at least as prominent and characteristic as sensory ones. 7. In alloæsthesia there are no corresponding mental symptoms and the patient's error is due solely to the fact that, on account of the peripheral defect, the mind receives imperfect information about the stimulus; allochiria, on the other hand, is essentially a mental manifestation in which there is a deficiency of the power of apprehending the feeling of "sidedness."

I shall add nothing to this brief account of the false or alloæsthesic allochiria beyond a few remarks later on the subject of diagnosis. Dyschiria however demands a fuller description. As was first pointed out by Janet, there are three distinct varieties of this condition, and these must be separately considered. There are, further, three manifestations of each variety—sensory, motor, and mental.

For the *first* variety, called "*simple allochiria*" by Janet, I have proposed the designation "Achiria." This term indicates that its essential feature is a defect in respect to the feeling of "sidedness" or "handness," which may be called the chirognostic sense. The three manifestations of this variety are as follows. First, sensory stimuli are perfectly appreciated and correctly localised with the exception of their side. They give rise to no feeling of "sidedness" whatever. It is not accurate to say that the patient *is in doubt as to the side* of the stimulus; he is quite sure that he has no idea on the subject and refuses to make any guess. The sensation experienced has certain peculiar qualities that will presently be mentioned. Secondly, if the patient is asked to carry out any movement with the limb in question he is unable to do so unless the limb is indicated in some other way than by the use of the words right or left; the reason for this is that he has lost the knowledge of the meaning of these words, either altogether or at all events when they are applied to the limb concerned. Thirdly, he is unable spontaneously to conceive the feeling of this limb and declares that he has no such part of his body.

For the *second* variety, called "complete allochiria" by Janet, I shall simply use the term "Allochiria," for it resembles the condition commonly defined under this term. The three manifestations of this variety are as follows. First, sensory stimuli *applied to* the affected side are invariably referred to the corresponding point on the opposite side of the body. This is done with an air of absolute conviction, so that, for instance, a patient affected with allochiria on only the right side feels no more certain that a touch is on the left side when it is applied on this side than he does when it really is applied on the right side. *Secondly*, if the patient is asked to carry out a movement on the affected side he invariably does so with the corresponding part of the opposite side, fully under the impression that he has carried out the movement correctly. This phenomenon has been given the name of "allokinesia," rather unfortunately, as I think, for so doing serves only to create an artificial separation between two aspects of what is essentially the same condition. Allochiria is neither a motor nor a sensory phenomenon, but a psychical phenomenon that has both motor and sensory manifestations. *Thirdly*, the chirognostic sense is altered as follows: In a bilateral case the patient can conceive of a given feeling of "sidedness" only when the opposite side is moved or stimulated. In a unilateral case he can conceive of the feeling of "sidedness" of an affected part only when he moves the corresponding part on the opposite side under the impression that he is moving the part in question; if he really moves the affected part, or if this is stimulated, he invariably gets the feeling of "sidedness" of the opposite part.

The *third* variety has been given the appropriate name of "Synchiria" by Janet. The three manifestations of it are as follows. First, a sensory stimulus evokes two simultaneous sensations, which are referred to the corresponding points on both sides of the body. Secondly, when the patient is asked to carry out a movement on the affected side he does so on both sides, though in so doing he gets only the feeling of "*sidedness*" of the affected part. *Thirdly*, the patient is unable, either spontaneously or when cutaneous stimulation is applied, to conceive the affected feeling of "sidedness" alone apart from the feeling of the corresponding opposite side, though he can conceive it when he moves both limbs under the impression that he is moving only the affected one.

On the introspective side there are many interesting matters in connexion with dyschiria, but the above-mentioned clinical features are sufficient to enable the condition to be recognised. As regards the distribution of dyschiria it may be general and bilateral, it may be unilateral, or it may concern only certain regions of the body. In a given part it may relate to all the functions of the part or to only some. Thus in the allochiric stage only painful sensations may be referred to the opposite side and not other sensations. These three varieties of dyschiria are three grades of the same pathological process, achiria being the most severe and synchiria the least. Probably any one may occur without the others, though it is true that achiria and synchiria have not hitherto been observed except in cases that at another period presented allochiria.

The last point that must be mentioned in this connexion is the peculiar nature of the sensation that a stimulus applied to a dyschiric part evokes. There are six characteristic features about such a sensation. First, it is abnormally persistent; a momentary touch evokes a sensation that lasts half a minute or longer. Secondly, its reaction time is delayed, being usually more than a second longer than that *of a normal sensation arising under the same conditions.* Thirdly, it is prevented by a simultaneous stimulus applied to any normal part of the body and is at once abolished by the subsequent application of any such stimulus; thus, if two touches are simultaneously applied, one on a dyschiric part and the other on a normal part, only the touch on the latter part is felt; and, again, if a *normal part* is touched while the patient is still feeling the persisting sensation that follows a touch on a dyschiric part he at once ceases to feel the abnormal sensation. Fourthly, it has a strong tendency to evoke an immediate motor response. Fifthly, it has a peculiar quality that the patient describes as a diffuse shuddering or tingling; this is always unpleasant, usually very disagreeable, and sometimes constitutes a horrible shudder. On account of this quality I have described it under the name of Phrictopathic Sensation. Sixthly, the feeling of personal ownership of the part stimulated is more or less gravely compromised. All these features are most marked in the achiric stage and least in the synchiric, as *may* be illustrated by considering the last one. In the achiric stage the patient can describe all the features of the stimulus as correctly as a normal person, but he is convinced that the point touched is *not on any part* of his own body and cannot understand how all the information about the stimulus reaches him. For instance, he might say "You are touching the back of a thumb with a blunt pin; it isn't my thumb and I have no idea where the thumb is." In the allochiric stage the part touched feels dead and as if belonging to the patient in only the vaguest way. In the synchiric stage two points seem to the patient to have been touched; the homolateral *one* feels strange, foreign and as if it were asleep, and the sensation has the other peculiar attributes mentioned above; the contralateral one feels the difference between the results of large intravenous injections and subcutaneous injection of the poison is due to the fact that in the former case it is not entirely saturated by the red cells before it reaches the marrow, which therefore shows signs of direct injury in extensive necrosis of cells. That there is hæmolysis of nucleated red cells is shown by the presence of naked nuclei in the marrow and in the circulating blood. These facts may explain the differences between anæmias of the pernicious type and of the secondary type. In tuberculosis, for example, there is a constant but slow absorption into the circulation of substances destructive to the red cells but this is so gradual that the toxin is completely anchored by circulating cells which it injures or destroys, as shown by accumulation of blood pigment in the spleen. But the toxin does not reach the marrow in an uncombined state and therefore does not injure it. So far as the marrow is concerned the lesion is the equivalent of hæmorrhage. The marrow is able to repair the injury in a normal manner. On the other hand, in pernicious anæmia large quantities of hæmolytic poison gain entrance to the circulation and do not completely combine with the circulating cells and reach the marrow, impairing its function. Similarly can be explained the reason why in certain severe secondary anæmias the blood picture of pernicious anæmia is produced. It is only necessary to postulate a time when the pathological process of tuberculosis, for example, is so acute that the red cells (diminished in number) cannot absorb all the toxin and that some of it reaches the marrow. The abnormal forms of red cells found in the blood may be due to too hasty metamorphosis of the injured marrow in the attempt to supply the demand for red cells. There is, perhaps, a hasty transition from megaloblast to erythrocyte without the orderly progression through intermediate and normoblastic stages. The resulting cell is thus larger than normal and bears more hæmoglobin. The poikilocytosis and the discharge into the circulation of immature (nucleated) cells are other expressions of this faulty hæmatopoiesis. The source of the poison in pernicious anæmia appears to be the alimentary canal—a view emphasised by Dr. William Hunter.

THE TOWN COUNCIL OF SOUTHEND-ON-SEA AND ITS MEDICAL OFFICER OF HEALTH.

As will be seen by reference to another column the town council of Southend-on-Sea has concluded by 12 votes to 11 to dispense with the services of Dr. J. T. C. Nash. We shall be surprised if this conclusion does not offend the better-informed burgesses of the town, and we shall be still more surprised if the council escapes an open expression of disapproval from the Local Government Board. This is what the inhabitants of Southend-on-Sea have now to think of. The present medical officer of health is being dismissed because his attention to duty has brought him into conflict with members of the town council. We are convinced that no medical man is likely to take Dr. Nash's place and to subject himself to the chances of such treatment. Certainly no medical man of any position in his profession or any experience of sanitary affairs will apply for Dr. Nash's post. What will be the position of Southend-on-Sea if the town council appoints a medical officer not fitted by his special attainments for the post? And—we hardly like to make the suggestion that follows—what will be the position of the borough if the municipal authority finds a medical man ready to act not as a sanitary expert and adviser but merely as the obedient servant of the town councillors? This is what will happen to Southend-on-Sea. An irremediable stigma will immediately be attached to the name of the borough and its position as a health and pleasure resort will be damaged beyond measure. Dr. Nash's annual reports have been received by us regularly and we ask the inhabitants of Southend to read and to digest the meaning of these figures which give the death-rates at Southend-on-Sea from measles, diphtheria, and typhoid fever since Dr. Nash's appointment in 1901 as medical officer of health:—

Zymotic Death-rates at Southend-on-Sea, 1901–06 inclusive.

—	1901	1902	1903	1904	1905	1906
Measles	0·33	0·06	0·18	0·07	0·13	0·05
Diphtheria ...	0·40	0·77	0·10	0·04	0·03	0·09
Typhoid fever ...	0·33	0·35	0·29	0·04	0·17	0·04

Arithmetic will show that the rates have dropped from an average of 0·32 during the first three years to an average of 0·08 during the last three; and further arithmetic suggests that the saving of life thus implied in a population of more than 40,000 is very considerable. This improvement in the "zymotic" death-rate has been paralleled by the improvement in the general death-rate, and there can be no doubt that Dr. Nash's strenuous work in putting down sanitary abuses and inspecting food-stuffs, especially the conditions of the shell-fish trade, is responsible for the significant alteration in the mortality figures. Certain members of the town council have now decided to get rid of Dr. Nash and the inevitable conclusion to which the public must come is one that will go far to spoil the position of Southend-on-Sea as a health or pleasure resort.

SENILE TREPIDANT ABASIA.

IN the *Boston Medical and Surgical Journal* of August 15th Dr. E. W. Taylor has called attention to a peculiar disturbance of gait in elderly people, which was described many years ago by Charcot as "senile trepidant abasia" but subsequently attracted little notice. He reports three cases. A woman, aged 83 years, came under observation. Up to three years previously she considered herself well except for the natural infirmity of her years. At that time she began to notice a disturbance in walking, particularly in starting. When once started she could progress fairly well, but her first movements were difficult, particularly if she was embarrassed by the presence of anyone. Descending a flight of stairs had become increasingly difficult and at last impossible. The heart was normal and no definite radial sclerosis could be made out. The grasp of the hands was good. The knee-jerks were active but there was no plantar reflex. In general the patient appeared vigorous for her years. When standing and asked to take a step forwards she could do so only after much difficulty and "muscular stammering." Taking short and uncertain steps she progressed a certain distance with much effort. There was no spasm or ataxia and her gait could not be described as feeble. Certain exercises were prescribed which she followed with definite temporary improvement. Two weeks later she was distinctly better and could to some extent walk alone. She complained of difficulty in writing similar to that of walking. She could write only after much effort. She was seen again two years later and had grown more feeble. She complained of spasmodic twitchings of the legs at night which kept her awake. The reflexes were very active. The heart was arhythmic and feeble, the pulse was 100, and the radial artery was hard. She had given up attempting to walk. In the second case the patient was a man, aged 75 years, who had had difficulty in walking for about two years. He complained that he "couldn't handle his limbs which were like sticks." Occasionally sharp twinges of pain ran down the legs which he attributed to rheumatism. The knee-jerks were normal and the plantar reflexes were slight. The clearly seen as a gap or faintly stained area in the endoplasm reminding one of a node of Ranvier in a nerve fibril. In citrated blood some forms strongly suggestive of longitudinal division have been seen: the appearances are not due to interlocking of spirals (which is a common phenomenon), but the spirillum becomes thickened and heavily beaded and for a part of its extent is split up into two lashes. In fresh specimens two spirilla are sometimes seen tugging in opposite directions at the thicker fused portion which is common to both of them. Attempts to demonstrate an undulating membrane or flagella have invariably failed. Spirilla by their last dying movements will clear a space around themselves in a granular background accurately corresponding to their curves but there is no evidence of an undulating membrane.

The question of flagella is not so easily settled. When stained by van Ermengem's or Löffler's process, a terminal filament is seen to be present. This is described as a flagellum by some observers. The filament gradually decreases in size from the full diameter of the organism to the farthest extremity, but this is unlike a true bacterial flagellum which is of equal diameter throughout its whole length and is always much narrower than the body from which it proceeds. Again, the filament continues the original direction of the spirillum itself and generally accurately continues its curves also, but the true flagellum does neither.

I am strongly of opinion that the filament in question is not a flagellum but an empty and collapsed sheath. A similar process is seen when two spirilla begin to separate before division. The cytoplasm shrinks and the ectoplasm or limiting membrane becomes stretched and a clear space appears. The sheath end may remain collapsed after division and remain so when stained, or it may appear only as an artifact due to the application of the powerful astringents used in the staining process.[1] In sections the spirilla are seen massed in the blood-vessels or sparingly in the tissues in the neighbourhood of hæmorrhages. They have not been actually seen in the parenchyma of organs or phagocytosed by cells but this may be due to inherent difficulties in demonstrating so fine an organism in such positions. At the height of the fever the spirillum is abundant in all the organs but is present in very small numbers or more generally absent altogether in spleen smears.

The spirillum is capable of three different kinds of movement: (a) Rapid translation from one field to another which is an evidence of high physiological activity and disappears quickly in citrated blood and in the circulating blood just before the crisis. (b) Vibratory or shivering motion. The organism maintains its corkscrew-like form but a thrill or shiver passes down from one extremity to the other. This movement is maintained for days and has been observed for nearly three weeks in vitro, becoming slower and slower as time went on. (c) An undulating or swaying motion which is the last sign of vitality.

When citrated spirillar blood is kept in vitro under varying conditions of temperature, light, &c., the process of decay is similar in all. The majority break up and disappear without undergoing any involution in form but in some cases solution is preceded by marked fragmentation and beading of the cytoplasm. In specimens stained by Romanowsky's method the beads stain a deep red like chromatin. Wisps of spirilla lie together in various stages of fragmentation and entangled in the mesh are deeply staining globular bodies (from 1 to 2 μ in diameter) the nature of which is unknown.

Cultivation.—This has not been successful. Spirilla have been recovered in the living state from the surface of dry agar as late as the tenth day. In citrated blood the spirilla live for varying periods (not later than the twentieth day in the author's hands). They appear to increase at first and then gradually to die out. Contamination with other organisms does not appear to affect the spirilla very markedly. Under the following conditions true multiplication results. The blood is citrated and centrifuged, the spirilla collect above the red cells; they are pipetted off, washed in normal saline and re-spun; the process is repeated a third or fourth time. The tubes are all set aside at room temperature in the ice box and after 24 hours a grey semi-opaque layer, like a "buffy coat," above the red corpuscles can be seen. If this is touched with a platinum needle it strings out like mucus and if examined will be found to consist of an enormous felted mass of spirilla. Under these conditions motility was lost after 48 hours and after that time they were incapable of producing the disease in a monkey.

Attempts have been made to keep the organisms alive by subculturing every day with fresh human serum, but though it appeared that some increase took place after the first transference there was certainly no increase in the subsequent subcultures. Other media have been tried without success.

To ascertain the fate of spirilla in the body of the bed bug (Cimex lectularius).—Monkeys and bugs were kept together in specially devised cages during the whole time that the former had spirilla in their blood. In these circumstances the bugs would feed readily and retired during the day to the "bug-traps," from which they could be removed. These bugs were kept and examined at varying intervals after their feed. The examination consisted of a careful dissection and separate smearing of all the principal viscera and salivary glands and the minute searching of stained specimens. In the first series several fed bugs were dissected daily up to the fourteenth day. Spirilla were found regularly up to the fourth day and not afterwards. In the second series the bugs were dissected in larger numbers (five or six a day) for 17 days. Spirilla were found as late as the seventh day. The following organs were scrutinised in almost every case: the upper alimentary tract, the lower tract with the rectum and cloaca, the anal glands, the Malpighian tubes, the salivary glands, the testicles, the vesiculæ seminales or the ovaries, and the ova in their several stages of maturation. It is important to note that in every case where spirilla were found they were always in *the upper alimentary tract and in the presence of fresh blood.* Bodies of unknown nature were found in the salivary glands and ducts of fed and unfed bugs. A short mycelial organism is often found in the internal organs. Flagellates were never seen.

To ascertain the occurrence of natural infection in bugs.—A series of 53 bugs were sent to me from the Arthur-road Hospital for Relapsing Fever at intervals extending over several weeks. These were generally caught at night and in many cases from the beds of patients during the pyrexial period—that is, at a time when the spirilla must have been present in the blood. The insects were carefully dissected and subjected to prolonged examination as above. In the stomach of *one bug only* were spirilla found and they were very few in number.

Transmission by bugs.—Bugs were fed on infected monkeys and then transferred to specially constructed cages in contact with a susceptible monkey. This experiment has been carried out six times and of these *the first monkey contracted the disease 11 days after first exposure to the bites of 57 fed bugs.* The monkey passed through an ordinary attack of the disease. None of the other five monkeys became infected though relays of fed bugs were introduced at intervals. (They subsequently contracted the disease after ordinary subcutaneous inoculation, so that the failure was not due to their being immune.) Although all the experimental monkeys are kept in one room, though in separate cages, no case of accidental or "natural" infection has ever occurred during the whole series of observations (extending over ten months). No monkey has ever proved to be naturally immune. It should be stated that three or four of the later experiments under the above conditions have been carried out in the inter-epidemic season in Bombay. Seasonal prevalence is a marked feature of relapsing fever in this city and very few cases occur during the hotter months of the year.

Animal experiments.—The following animals have been found susceptible to infection with the Bombay spirillum: monkeys, white mice, white rats, white rabbits, black rats (mus rattus), and brown rats (mus decumanus), and guinea-pigs in order of susceptibility. A goat has proved refractory on several occasions, though pyrexia was induced by each injection of spirillar blood. Pigeons are insusceptible. In wild rats a double infection of spirillum Obermeieri and trypanosoma Lewisi was often seen. In monkeys (when the blood is taken from a human source) the spirilla generally appear on the third day after inoculation, but there is some evidence to show that repeated passages through monkeys may reduce the incubation period large and important contingent of foreign visitors is at the mercy of any hygienic indiscretion on the part of the local authorities we have thought it incumbent upon us, on our own initiative and following a precedent already set by us in respect of the water-supplies of Chicago and other municipalities, to form an opinion as to the advisability or otherwise of the scheme. We may add, however, that in the carrying out of our inquiry every assistance has been afforded to us by the mayor, M. Mottet; M. Luya, the town surveyor; Dr. Bleicher, the public analyst; and Dr. Marty, whose kindness in facilitating the collection and dispatch of our samples we gratefully acknowledge.

---

[1] Dr. S. Rowland kindly made a careful examination of the spirilla in a fresh state for evidence of flagella with an oil immersion paraboloid. This instrument, by cutting off all focal light and giving powerful dark-ground illumination, is specially adapted for revealing such minute structure. He saw no evidence of flagella.

Incidentally our inquiry bears upon the suitability of lake water in general for domestic consumption and we therefore embody a synopsis of the results obtained by other observers. Although picturesquely situated in a valley surrounded by imposing mountains, snow-clad for several months in the year, and in proximity to Lake Bourget, the Aix district is singularly poor in water suitable for domestic use. No rivers or streams of any size find their way into the Aix Valley and such streams as there are usually run dry during the summer, so that hitherto the water-supply of Aix has been exclusively drawn from springs issuing at the foot of Mount Revard. This water, which is of a very high quality, is stored in three reservoirs (Chevalley, 600 cubic metres; Boncelin, 370 cubic metres; and Chatelard, 1440 cubic metres).[1] The total yield amounts to about 3500 cubic metres daily.

Aix-les-Bains has a resident population of 8300 but during the season close on 40,000 visitors patronise the 63 hotels and 141 chalets and furnished houses provided for their reception. The comparative paucity of potable water seems strange in view of the abundance of the thermal springs which from time immemorial have yielded upwards of 1,000,000 gallons daily at a temperature of between 45·6° and 46° C. in addition to 27,000 gallons of comparatively cold water from another spring which is principally utilised for the purpose of modifying the temperature of the thermal springs for baths and douches. The springs of St. Simon and Massonat furnish a limited supply of slightly mineralised water which has been utilised to some extent for therapeutical purposes. Quite recently, however, a spring yielding an excellent mineral water was unearthed at Corbières, on the flanks of Mount Revard, and this was baptised "Eau des Deux Reines" in commemoration of the fact that the two Queens of Holland were among the first to appreciate the qualities of the newly discovered spring. The geological origin of the "Deux Reines" water insures absolute freedom from contamination, and repeated analyses by independent authorities have shown it to be microbiologically one of the purest of medicinal and table waters. Its total dry residues do not exceed nine grains per gallon, so that it is well adapted for consumption as an *eau de régime* and as a neutral, slightly diuretic table water.

This water, which contains free oxygen in solution, is too valuable to be made use of for domestic purposes, so that it does not come within the scope of the present article. The demand for additional water supply, long foreseen, became particularly urgent in 1906 in consequence of the prolonged drought, and the municipality was invited to give to the matter its serious attention. For some years past in the height of summer it has been necessary to curtail the water used for watering the streets—a real hardship in view of the enormous vehicular traffic and the yearly increasing number of motor-cars that bring visitors to Aix or pass through on their way to more distant parts of the continent. Even the domestic supply has had to be suspended at times, the mains being cut off at night, thus entailing much discomfort and some risk to the inhabitants,[2] in addition to the danger of contamination by suction into the empty pipes from the surrounding soil.

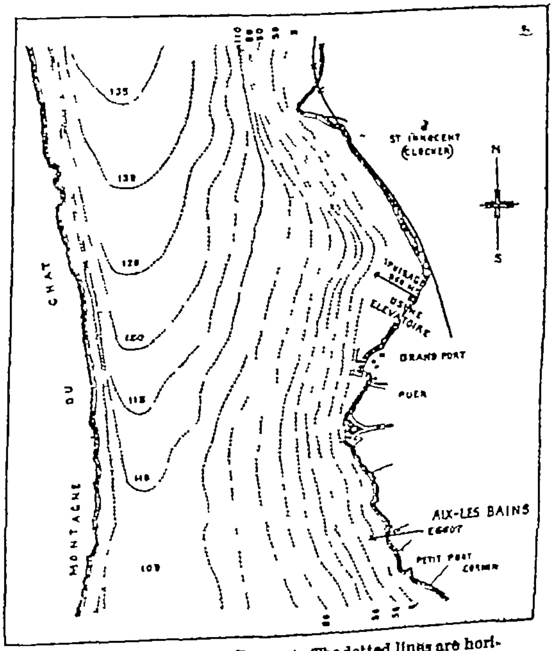
Inasmuch as all available sources of spring water have long since been requisitioned, it was only natural to consider the possibility of utilising the water of Lake Bourget. This, the largest of French lakes, is some 12 miles long by two or three miles wide, and covers an area of over 11,000 acres. It attains in parts a depth of 150 metres, with an average of about 140 metres. Although it communicates with the Rhone through the Canal de Savières at the northern end and receives the Sierroz, the Leysse, and the Seran rivers, there is practically no current of water through the lake during the summer months, although during the autumn and spring it is no doubt efficiently scoured by extra water from the heavy rains and the melting of the snow on the neighbouring mountain slopes which raises the level of the Rhone to such an extent as to cause it to overflow into the lake. It was only natural that an endeavour should be made to utilise this immense natural reservoir for general and domestic purposes. Aix-les-Bains, which is at a distance of about one and a half miles from the lake, is the only town of any size on its shores, although there are a few small hamlets. The sewage of the town is conveyed into the lake through pipes which discharge at a distance of 400 metres from the bank and 1600 metres from the proposed place of captation. Moreover, the lake naturally receives all the sulphur water from the thermal establishment which amounts to upwards of 1,000,000 gallons daily. The matter has received attention at intervals for many years past but last year a special commission was appointed to study the question, more particularly with the object of ascertaining the degree of purity of the lake water at different spots and depths and incidentally to ascertain the best place whence to draw the supply. This commission drew up a report from which we glean the following data.

The best results in respect of purity were given by samples taken at 15 metres depth, as shown in the following details. *At 15 metres depth*: free oxygen in solution, 8·625 per litre; total hardness, 16·5°; permanent hardness, 4·5°; number of aerobic germs per cubic centimetre, 116. At 25 metres depth: free oxygen in solution, 8·128 per litre; total hardness, 17°; permanent hardness, 4·5°; number of aerobic germs per cubic centimetre, 129.

The temperature in degrees centigrade at various depths as ascertained by M. Delebecque was as follows:—

	Feb	March.	June	July.	August.
At the surface	3·7	8	17·8	24	21·2
At 15 metres depth	3·7	6·3	8·1	10·2	14·2
At 20 metres depth	3·7	5	6·7	7·3	8·8
At 25 metres depth	3·8	5	6	7	7·2

Beyond 20 metres depth the temperature varies within very narrow limits, while at 15 metres the oscillations are so pronounced that in August water from that depth may reach 14·2° C. It was decided therefore to establish the intake at a depth of not less than 20 metres. Lake and river water, it is well known, always contains a certain proportion of nitrates derived from the washings of the soil in which these salts occur as the result of the process known as nitrification. This process of nitrification has been thoroughly investigated by M. Schloessing in respect of Lake Bourget. His investigation bore on samples



Map showing part of Lake Bourget. The dotted lines are horizontal contours of the bottom of the lake and show lines of equal depth of water in metres as marked.

---

[1] A cubic metre for all practical purposes is 220 gallons.

[2] The reality of the risk may be inferred from the fact that when the town hall took fire last year no water-supply was available and it had to be allowed to burn itself out.

Bahadur Choksy, M.D., of the Arthur Road Hospital, by whose courtesy constant access to patients was allowed.

Should it in the future be found advisable to specify the Bombay spirillum as a subvariety I suggest that it should be called "S. Carteri," as a tribute to the memory of Vandyke Carter of the Bombay Medical Service, whose monograph, "Spirillum Fever," remains to this day a monument of industry and scientific accuracy.

The following are the more important results obtained after a further six months' work on the above subject:—

1. It was found possible to transmit the disease from an infected monkey to an uninfected by means of repeated puncture from the former to the latter with a grooved needle. A similar result was obtained with freshly drawn infected defibrinated or citrated blood. The "artificial proboscis" experiment proves that spirillar fever can be conveyed without any developmental stage and suggests that if the infection is carried by insect agency the method is more likely to be by a soiled proboscis (as is probably the case in some trypanosome infections) than through the medium of a developmental stage.

2. It was found possible to transmit the disease to monkeys by feeding with infected blood. The dose required was rather larger than by subcutaneous injection and the incubation stage was prolonged by two or three days. Spirilla (whether specific or otherwise) have been seen several times in the urine of infected patients, but attempts to transmit the disease by injection of, or feeding with, this secretion have failed. These facts suggest the possibility of an alternative route in human epidemics and certainly opportunities are not wanting for such transmission amongst the native population.

3. A monkey was injected with blood from a patient who was in the apyrexial period and whose blood was proved to be free from spirilla. The monkey failed to develop the disease at the usual time but five days after the injection of the monkey the man had the relapse and the monkey a primary attack together; spirilla appeared in the blood of each and the disease ran its usual course.

This suggests that (*a*) the spirillum remains in the circulating blood in an unrecognised or ultra-microscopic form; (*b*) that the blood is infective during the apyrexial as well as the pyrexial period; and (*c*) that there is a definite cycle of development which comes to a crisis with the appearance of visible spirilla at definite intervals.

Bombay.

Reviews and Notices of Books.

Practical Physiological Chemistry (designed for Use in Courses in Practical Physiological Chemistry in Schools of Medicine and of Science) By PHILIP B. HAWK, M.S., Ph.D., Demonstrator of Physiological Chemistry in the University of Pennsylvania. With two plates of absorption spectra, four coloured plates, and 126 figures in the text. London: J. and A. Churchill. 1907. Pp. 416. Price 16s net.

THE author states that the main point in which his plan of setting forth his subject differs from those previously proposed is in its treatment of the foodstuffs and their digestion. The subject of decomposition products of proteids, although it is impracticable to include its study in an ordinary course of physiological chemistry, is given in Chapter IV. (pp. 65–82), and a short chapter (pp. 139–47) is devoted to the examination of "*feces*" for the purpose of diagnosis. The author's plan, however, will be best understood by enumerating the order of the subjects: carbohydrates, salivary digestion, proteids and their decomposition products, gastric digestion, fats, pancreatic digestion, bile, putrefactive products, "*feces*," blood, and milk; epithelial, connective, muscular, and nervous tissues; urine (normal and abnormal), and quantitative analysis of urine, milk, gastric juice, and blood. We do not find much that differs from the subject as treated in English text-books of the same standard. The tests for carbohydrates and other groups are fully given under the head of carbohydrates and proteids. A [illegible] iven in order to facilitate the student's review of the properties of the substances comprehended in these groups. There are also useful schemes for the detection of unknown substances in solution—e.g., carbohydrates, proteids; but we do not find one dealing with complex mixtures—e.g., of carbohydrates, proteids, and bodies of physiological importance.

The old classification of proteids is adhered to and in giving the technique of the colour reactions the author explains the cause to which they are due. There are some good drawings of crystals of edestin, excelsin, and the products of decomposition of proteids and of the fats. Fibrinogen is stated to be "perhaps the most important of the proteid constituents of the plasma"; serum-globulin and serum-albumin are regarded as probably not individual substances. The differences between blood plasma and blood serum are not properly stated at p. 150. The coloured figures of crystallised hæmoglobin are good and true to nature; we cannot say quite the same for the two plates of absorption spectra which preface the volume. Some of the methods in use in this country for counting the blood corpuscles and estimating the hæmoglobin are omitted. In the chapter on Muscle we think that the author is right in dividing his experiments into those (1) on living muscle and (2) on dead muscle. The long chapters on Urine (pp. 226–379) are much the same as in similar text-books. An appendix of about ten pages sets forth the chemical composition of the various reagents used. There is a good index.

On the whole, we think that the English student will not find any great advantage in the use of this work in preference to English text-books.

American Practice of Surgery: a Complete System of the Science and Art of Surgery. By Representative Surgeons of the United States and Canada. Editors, JOSEPH D. BRYANT, M.D., and ALBERT H. BUCK, M.D., of New York City. Complete in eight volumes. *Profusely illustrated.* Vol. I., 1906, pp. 818. Price $7, 8, or 9, according to binding. Vol. II., 1907, pp. 778. Price as Vol. I. New York: William Wood and Co.

THE vast extent of modern surgery is shown by the size of this treatise, of which two volumes are before us. This "Practice" claims to be purely American, yet only North America is represented; the publishers in their announcement say that "no foreign writers have been invited to take part in the work," but several of the articles have been written by Canadians. We fail to see any benefit in this limitation to one or two countries beyond the practical convenience which an editor would find in having his contributors within a reasonable distance. Probably the intention is an appeal to national sentiment.

The first volume begins with an account of the evolution of American surgery by Dr. Stephen Smith of New York. He divides it into three periods, during the first of which no medical schools existed, the second extended from the formation of medical schools to the introduction of anæsthesia and antiseptics, and the third period is still in progress. A readable account is given of the chief members of the profession from the early times to the present day. The more important surgical works also are mentioned and a brief summary is given of the main contributions to surgery made by American surgeons. Dr. Aldred Scott Warthin of Ann Arbor writes on Inflammation. We quite agree with him that it is unwise to attempt to limit the name inflammation to processes caused by micro-organisms. The process is essentially the same whatever the cause. Dr. Albert G. Nicholls of Montreal has contributed the section on Disturbances of Nutrition. His article is well written and fully illustrated with examples of hypertrophy and atrophy and other nutritional changes. The only criticism that we have to make is that pressure atrophy of bones is many years' attentive study of lake water by competent authorities tend to show that in lakes of considerable size the water is almost free from extensive contamination. Such contamination as results from the discharge of sewage and impure river water is restricted to a very limited area and is soon disposed of by the various oxidising agencies aided by sunlight and sedimentation. The importance of the last factor is in proportion to the absence of current and other causes of motion. At a distance of 200 metres and upwards from the lake shore all trace of soil contamination disappears, and although the surface water still contains a moderate proportion of micro-organic life the water at depths between 15 and 20 metres is remarkably constant in point of purity and temperature. These general results, confirmed by our independent examination of the water of Lake Bourget, authorise the view that this water is eminently suitable for domestic use and that its employment is unlikely to be attended by any injurious effect on the public health. The very moderate amount of micro-organic life which it contains will, no doubt, judging from experience elsewhere, be still further reduced by filtration and we may congratulate the municipality of Aix-les-Bains on having been able to remedy a very obvious shortcoming in an important department of the public service.

THE TOWN COUNCIL OF SOUTHEND-ON-SEA AND ITS MEDICAL OFFICER.

ONLY one of the 24 members of the Southend borough council was absent at the ordinary monthly meeting on Tuesday evening last, when the Health Committee submitted recommendations with regard to the re-appointment of Dr. J. T. C. Nash as medical officer of health. At the August meeting his formal appointment was opposed and as he declined to accept £500 instead of £600 a year it was decided to advertise for an officer at the lower figure. At a subsequent meeting, however, a resolution was carried that the original motion should be considered, and this week the Health Committee brought up recommendations accordingly. The gallery was crowded with burgesses who manifested that they were not in sympathy with the council's treatment of Dr. Nash; in fact, so pronounced and frequent were their comments that the mayor had to request that no feeling, one way or the other, should be expressed by the public.

Alderman **J. FRANCIS**, chairman of the Health Committee, in moving the recommendations, said: I do not think that any chairman of a committee of this council has ever before been placed in the position in which I find myself to-day. It is very well known that the work of this council is divided into departments, that each department is controlled by a committee, and that with the committee there is a chief official, and under him a staff. It has been customary, whenever a chief official is required for one of the departments, for the committee having charge of the work to deal with the applications and to bring to this council, as a rule, three names, so that the council may ultimately decide who should have the appointment. And having once made the appointment the chief official deals directly with his committee, and the committee through its chairman with the council. If at any time it became necessary to reappoint a chief official the recommendation of the particular committee has always been accepted by the council. I think it will be admitted that this is a good and proper custom. At the last monthly meeting of this council the good old-fashioned custom was entirely ignored and for the first time in the history of this borough the recommendation of the Health Committee to reappoint a chief officer was thrown overboard without one word of explanation or any reason whatever either to the official concerned or to the chairman or to the committee as a whole. I suggest, Mr. Mayor, in the interest of good government that that ought not to be. I suggest most seriously that if any members of this council are of opinion that an official is not a proper man to remain in the service of the corporation the duty of those members is to inform the chairman of the committee concerned so that he may bring the matter before the members of his committee and take their opinion and instructions. Again, speaking in all seriousness, I say that this is the proper course to adopt and although it has been departed from on this occasion I hope it will never be departed from again. What is the result? We are to-day placed in a very serious position. The town has had an advertisement the result of which it may take years to eradicate. In the first place, although we have not yet heard much from the Local Government Board, we are in conflict with that Board; secondly, we have had a very strong protest from the members of the medical profession; and thirdly, I must not overlook the fact that, rightly or wrongly, the opinion is that if one chief official has been unfairly treated there must be unrest among other chief officials—that goes without saying. There is another serious aspect of the matter—the financial aspect. Members of this council, as business men, know that when money is being lent—we will say, if you like, upon security of property—not only is the property looked at but the borrower is also. No man who lends money upon security of property wishes to buy trouble. Therefore, he looks at the man to whom he is asked to lend so that he may form an opinion whether his interest will be promptly paid when it becomes due. What applies to private persons applies equally to a corporation, and if you care to study carefully the list of corporation stock you will see that for yourself. You will find one borough 3¼ per cent. stock quoted at a lower rate than our own 3 per cent. That speaks for itself, because there are reasons. I have already had a warning note—in fact, notes—that if this corporation loses its reputation for fair dealing we shall have greater trouble in the days to come, when we shall have to face an expenditure amounting to a quarter of a million sterling and when we must have the money at any price. It behoves us, therefore, if we have made a mistake, to put our house in order before it is too late. At the last monthly meeting of the council I moved the reappointment of Dr. Nash quite as a formal matter, without having the slightest idea that anyone would oppose it. I do not think it necessary to advance any further reasons why Dr. Nash should be reappointed, but I will give you the terms of his original appointment. Dr. Nash was appointed medical officer of health in 1901 at a salary of £400 per annum, rising by annual increments of £25 to £500. But there was a stipulation that Dr. Nash should be allowed to undertake privately analyses, laboratory work, and other duties of a similar character. In 1903, when the salary automatically became £450, it was decided to increase it to £500, and one of the reasons given at the time was that although up to then Dr. Nash had had the right to charge certain fees, as a matter of fact he had not charged those fees. He stated that in the interests of the borough it was far better that there should be no such charges but that the medical profession should be encouraged to send specimens to the laboratory without anything having to be paid by the town therefor. Mention has been made of the duties which Dr. Nash had to perform in connexion with the schools. It was distinctly understood when he was appointed that he should merely visit the schools and see that the sanitary condition was in proper order. In 1906 the salary was increased to £600, and one reason for the increase was the large increase in the work of the department, and another main reason was the large amount of work which Dr. Nash undertook in connexion with the Hobart case, work quite outside his duties as medical officer. Had that work been performed by an expert the cost, as the Law and Parliamentary Committee knows, would have reached at least £350. The laboratory work is not very well understood by outsiders and not by certain members of the council. I am not saying that offensively, because if you are working on one committee you cannot be expected to be acquainted with the details of another committee. In 1905 Dr. Nash examined 923 specimens at the laboratory—that in itself is work quite apart from the duties of medical officer of health. The sanatorium work is, perhaps, better understood. I have heard remarks about the expenditure in connexion with the sanatorium. It may be interesting to this council to know that for the year ended March, 1901—before Dr. Nash was appointed—the expenditure was £1865; in the year ended March, 1906—notwithstanding that the population had almost doubled—the expenditure was only £1724. Those figures have never been given to the corporation before and I hope they will prove that there is someone at the helm who has had regard for the expenditure. Here are some more figures: During the four years, 1899 to to be simple and elementary Mr. Ashcroft sometimes falls into error, making inexact and erroneous statements. Part IV. is entitled "The Human Soul," a term which he retains, defining it as "indicating all that vast world of thought and consciousness, emotion and will, which constitutes the real life of man and the higher development of which lifts him in so special a sense above the other denizens of the world." To its analysis, after considering the scope of the older schools of psychology, he brings the methods of the new experimental psychology and then applies them to the moral regulation of conduct. He discusses various systems of practical ethics, notably the Hindu, Buddhistic, Confucian, and Christian systems. He refers to Kant and his "categorical imperative," and then examines the principle of pure altruism, which affords the basis of his progressive system of ethics. In the concluding chapter of this section, entitled "The Human Outlook," Mr. Ashcroft considers the application of this "gospel of science and humanity" and its promise for the future.

Mr. Ashcroft's philosophy is noteworthy if for no other reason because it is constructive in its aims and not purely iconoclastic or negative like that of the agnostic and the blind fatalism of the pure materialist.

Green's Encyclopædia and Dictionary of Medicine and Surgery. Vol. III., Earth Burial to Gummi Indicum. London and Edinburgh: William Green and Sons. 1907. Pp. 535. Price 12*s.* 6*d.* to subscribers.

THE third volume of this important work contains 50 articles of more than 1000 words in length, over 100 articles of from 80 to 900 words, and 935 short articles and headings, varying in length from ten lines to a few words. Amongst the subjects considered we may draw attention to those of eclampsia, human embryology, epilepsy, the clinical examination of the eye, filariasis, the examination (physical, chemical, and bacteriological) of pathological fluid, furunculus orientalis, the gastro-intestinal diseases of children, general paralysis, and glycosuria, all of which are thoroughly up to date. The article on eclampsia, for instance, is excellent, the etiology of the affection being very thoroughly described. The symptoms and treatment are fully gone into. The article concludes with a description of the theories of thyroid inadequacy and of the placental or chorionic origin, so that the reader has here the whole subject brought up to date by Dr. H. Jellett. Sir John Halliday Croom, as was to be expected, writes lucidly on ectopic gestation, the treatment of this serious affection being most explicitly laid down accordingly as it has to be carried out before rupture, at the time of rupture, after rupture, or after suppuration, and so on, of the fœtus. To Dr. J. W. Ballantyne has been intrusted the article on embryology and he has handled the difficult subject in an admirable manner and illustrated it by some excellent plates. Very useful remarks and methods will be found under the heading of enemata. The late Dr. A. L. Gillespie writes on enteroptosis. The subject of epidemiology has been considered by Dr. A. Davidson who details the methods of studying the subject and considers the whole matter under the heads of (*a*) epidemic movements, embracing here the secular mutations, the multiannual fluctuations, the epidemic or short period waves, the seasonal fluctuations, and oscillations; (*b*) the law of anticipation; (*c*) the association and antagonism of epidemic diseases; and (*d*) the evolution and involution of epidemics. We find, also, a very concise but complete section on expectoration. One of the best articles in the volume is that by Mr. W. Adams Frost on the clinical examination of the eye, which embraces the examination of all the different structures of this organ in a very comprehensive manner. The attention of the reader may also be directed with advantage to the article on the examination of the fæces. Mr. Alban Doran, as was to be expected, contributes an excellent account of the affections of the Fallopian tubes in his usual lucid style. The article on filariasis by Dr. G. H. F. Nuttall is the most thorough exposition of this subject that we have read; it is illustrated by some excellent drawings of these parasites; the pathological effects produced are succinctly described and the various species of filariæ are enumerated and described. The student will also find in the section on the examination of pathological fluids by Dr. T. H. Milroy and Dr. D. A. Welsh all the important facts of this subject. Dr. R. W. Felkin writes on oriental sore; the relationship of the Leishman-Donovan body is alluded to, thus bringing the subject up to date. The author, however, has not mentioned the treatment that has been found very successful on the North-West frontier of India—namely, that of covering the sore with a thin sheet of lead just embracing the lesion. This is by far the best method of treating these obstinate sores. Such are a few of the subjects treated of in this volume, space alone forbidding us to allude to more of the articles. When completed the work will form a valuable addition to the library of the physician or surgeon.

The Dispensatory of the United States of America. By Dr. GEO. B. WOOD and Dr. FRANKLIN BACHE. Nineteenth edition. Thoroughly revised, largely re-written, and based upon the Eighth Decennial Revision of the United States Pharmacopeia. Philadelphia and London: J. B. Lippincott Company. 1907. Pp. lxii.–1947. Price £1 11*s.* 6*d.* net.

THE first dispensatory was published in 1833; since that date the work has received full legal recognition. The present edition comes opportunely, in view of the great interest that is being taken in the question of the purity of foods and drugs in the United States at the present time. The compilation represents the expenditure of much labour, skill, and care that must necessarily be bestowed upon a standard work. The editorial staff includes the recognised authorities in the United States on the various subjects treated. To Professor H. C. Wood, professor of materia medica and therapeutics in the University of Pennsylvania, has been intrusted the task of revising the sections on botany and materia medica with the uses of the drugs and preparations; to Professor Joseph P. Remington, professor of theory and practice of pharmacy in the Philadelphia College of Pharmacy, the section on pharmacy and pharmaceutical preparations; and to Professor Samuel P. Sadtler, professor of chemistry in the Philadelphia College of Pharmacy, the sections on theoretical chemistry and toxicology. The preparation of the index of diseases was undertaken by Dr. H. C. Wood, jun., and the article on Serum Antidiphthericum was contributed by Dr. M. S. Rosenau, director of the Hygienic Laboratory of the United States Public Health and Marine Hospital Service. To these should be added the name of Dr. Albert B. Lyons of Detroit, who assisted directly in that part of the revision concerned in bringing the chemistry of the alkaloids into line with modern research.

The work is divided into three parts, Part I. containing the discussion of all the remedies recognised by either the United States or British Pharmacopœias, Part II. dealing with non-official drugs and preparations, while in Part III. are considered the tests and test solutions of the two Pharmacopœias, weights and measures, the art of prescribing, and other matters relating to pharmaceutical work. This part includes also the National Formulary in abstract. The arrangement throughout is alphabetical, although there is a very complete index.

Altogether this dispensatory is a monumental piece of work which reflects great credit on all those who shared the enormous task of its compilation and revision.

both from yellow fever and from malaria, thus enabling the construction of the Canal to be carried on in security. The practical sanitary labours of Colonel Gorgas have given the world the most brilliant possible example of what such work can effect in the tropics.

9. Waldemar Mordecai W. Haffkine, C.I.E. In 1893 he discovered a method of inoculation against cholera and proceeded to India in order to persuade the people to use it on a large scale. In 1896, on the outbreak of plague in India, he elaborated a similar method of inoculation against that disease also. Since then over 6,000,000 doses of his prophylactic have been prepared and issued by the Government of India and it has been shown to reduce the mortality among the inoculated to one-sixth. Prophylactics against other diseases have been prepared on the same principles.

10. Dr. Arthur Looss, professor of parasitology, School of Medicine, Cairo. He has done much work of great value in connexion with parasitology in general. His discovery of the fact that the young of the parasites called ankylostomes, which produce fatal anæmia in thousands of persons in many tropical countries, enter the body by the skin is one of leading importance.

11. Dr. Theobald Smith, professor of comparative pathology, Harvard University. In 1893 he discovered a new kind of blood parasite in the so-called Texas fever of cattle, and also showed that it is carried from diseased to healthy animals by ticks—a work of great importance in connexion with diseases both of man and animals."

ASYLUM REPORTS.

Dorset County Asylum (*Report for the Year 1906–07*).—The number of patients in the asylum on March 31st, 1907, was 802, being five less than at the corresponding time last year. The county patients numbered 605, out-county patients 40, and private patients 157. During the year 1906 there were 153 patients (78 males and 75 females) admitted into the asylum, and of these 40 (19 males and 21 females) were private cases. Dr. P. W. Macdonald, the medical superintendent, reports that the number of first admissions is six less than last year, which he considers may be taken as an indication that at the present time no actual increase of insanity is manifesting itself among the population from which the bulk of the patients are drawn. He further adds that the type of case admitted during 1906 was not generally of a favourable character, in spite of the fact that only two cases of general paralysis were included among the admissions. The recovery-rate for 1906 was a high one, being 46·2 per cent. calculated on the total number of persons admitted. 67 patients (40 males and 27 females) died during the year, and the causes of death call for no special mention. The rate of maintenance, which has for some years past been 9*s.* 4*d.*, was only 9*s.* 0½*d.* during the whole of 1906. The chairman of the visiting committee reports that six new cottages for attendants have been erected under the supervision of the medical superintendent and the county surveyor without the assistance of a contractor, the inmates of the asylum contributing to the skilled and unskilled labour to a large extent. This course was adopted in consequence of the tenders received being considerably higher than the estimated cost, the actual outlay being £1430.

West Sussex County Asylum, Chichester (*Report for the Year 1906–07*).—There were 750 patients on the books of this asylum on Jan. 1st, 1906, of whom 205 were out-county cases and 14 were private patients. During the year 1906 there were 162 patients (71 males and 91 females) admitted. Mr. H. A. Kidd, the medical superintendent, reports that the character of the cases admitted continues to be bad. He has drawn up a table giving an index of the expectation as to the chances of recovery in these cases—viz., recovery probable, 34; recovery possible 18; recovery improbable, 47; and recovery impossible, 63; in other words, no less than 68 per cent. of the cases were of an incurable nature, and in only 21 per cent. was there a reasonable chance of recovery. The mean age of admission was 42, and ten persons were over 70 years of age. Of the 67 patients discharged, 43 were sent out as "recovered" and 21 as "relieved." There were 76 deaths (42 males and 34 females), giving a death-rate of 8·33 on the total number of persons under treatment. The vice-chairman of the visiting committee states in his report that a surgery and isolation block are in course of erection, and further that the building of a nurses' block has also been begun. The committee for a long time has had under consideration the question of providing separate accommodation for private patients and has now decided in the first instance to adapt one ward for that purpose at a cost, including fittings and equipments, not exceeding £120, to be charged to the private patients' account. The minimum charge for such patients is to be £1 1*s.* per week. The committee has also been considering for some years the question of formulating a scheme of superannuation allowances for the officers and staff of the asylum. This has now been completed and presented to the West Sussex county council for its approval. The profits derived from private patients for the year ending March 31st, 1907, were £407 15*s.* 2*d.*; from out-county patients £2356 14*s.* 10*d.*; together making £2764 10*s.*, out of which there has been spent on account of the surgery and isolation block the sum of £1068. The weekly rate of maintenance for cases belonging to the West Sussex Union has been reduced to 10*s.* 6*d.* The farming and garden account shows a profit of over £1100.

Looking Back.

FROM

THE LANCET, *SATURDAY*, Sept. 19th, 1829.

LECTURES ON THE EYE.

To the Editor of THE LANCET.

SIR,—Permit me to state the inconvenience, many students are put to, who receive their surgical education at the west end of the town. There are *four or five lecturers on surgery*, and strange to say, only one of them delivers lectures on the pathology of the eye. Now considering the number of diseases this beautiful and delicate organ is liable to be affected with, and the enormous sums received from pupils for attendance on these lectures, surely, some of the gentlemen might make an extension of a few lectures to their "*extended courses*,"* at once beneficial to their students, honest as regards themselves, and conferring that information which is calculated to alleviate, in a greater or less degree, the sufferings of mankind.

The insertion of this letter as early as possible will much oblige, and should this hint be the means of producing a reformation in this branch of surgical education, I shall be greatly rejoiced at having called the attention of the Surgical Lecturers to the subject. I am, Sir, yours,

H. W. DEWHURST.

September 15, 1829.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8072 births and 3793 deaths were registered during the week ending Sept. 14th. The annual rate of mortality, which had been equal to 11·5, 11·8, and 12·3 per 1000 in the three preceding weeks, was again 12·3 per 1000 in the week under notice. During the first eleven weeks of the current quarter the death-rate has averaged 12·0 per 1000, the rate during the same period being 11·9 per 1000 in London. The lowest death-rates in the 76 towns last week were 4·7 in Handsworth (Staffs), 5·8 in Hornsey, 6·0 in West Bromwich, 6·8 in Burton-on-Trent, and 6·9 in King's Norton; the highest rates were 17·4 in Sunderland, 17·5 in Rotherham, 17·7 in Sheffield, 18·0 in St. Helen's, and 20·0 in Tynemouth. The 3793 deaths in the 76 towns were slightly in excess of the number in the previous week, and included 485 which were referred to the principal epidemic diseases, against numbers increasing from 362 to 471 in the six preceding weeks; of these, 278 resulted from diarrhœa, 95 from whooping-cough, 39 from diphtheria, 35 from measles, 26 from scarlet fever, and 12 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered last week in Tottenham, Hornsey, York, Aston Manor, King's Norton, Newport (Mon.), or in

The Dublin Journal of Medical Science.—In the August issue of this periodical is contained the annual report of the Rotunda Hospital for 1905–06, compiled by Mr. E. Hastings Tweedy, Dr. Arthur Holmes, and Dr. R. J. Rowlette. It offers as usual material for study by all obstetricians. Dr. Charles Greene Cumston of Boston reports a case of acute metastatic gonorrhœal myositis and discusses the diagnosis and treatment of this rare affection which is scarcely mentioned in many text-books. Dr. Charles T. Costello writes on blackwater fever but comes to no certain conclusion as to its etiology, though he suggests that it may be due to some special parasite.

The Birmingham Medical Review.—In the July issue of this review is published a Presidential address by Dr. Robert M. Simon to the Birmingham and Midland branch of the British Medical Association in which he discusses the subject of character and temperament and concludes that the brain and the thyroid gland are the only two organs of the body which directly influence them. Following this address is a severe criticism of the recent policy of the Association written by an ex-Vice-President under the title of "Medical Science *v.* Trades Unionism."

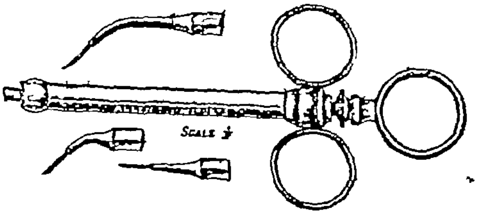
Guy's Hospital Gazette.—Useful articles are somewhat buried, as a rule, in the pages of the hospital magazines and we are glad to have the opportunity of calling attention to the first of a series of lectures on the Significance of Variation in the Constituents of the Urine, delivered by Dr. F. G. Hopkins and published in the issue of this gazette of August 24th. The subject of nitrogen excretion is dealt with and the meaning of the urea and of the ammonia in the urine is discussed with more appreciation of the real difficulties inherent in the chemical problems involved and of the uncertain nature of the results arrived at than is always evident in the writings of physiological chemists.

St. Bartholomew's Hospital Journal.—In the August number Surgeon W. Perceval Yetts, R.N., records a case of ascariasis—infection with lumbricoid worms—which presents points of interest. The number of parasites ultimately expelled was very large and the symptoms were suggestive of pernicious anæmia, the blood showing reduction in the number of red corpuscles, with megalocytes and poikilocytes present. There was no eosinophilia. The patient suffered from a neurasthenic condition which disappeared on expulsion of the worms by santonin.

New Inventions.

A NEW ASEPTIC SYRINGE FOR INDUCING LOCAL ANÆSTHESIA IN DENTISTRY.

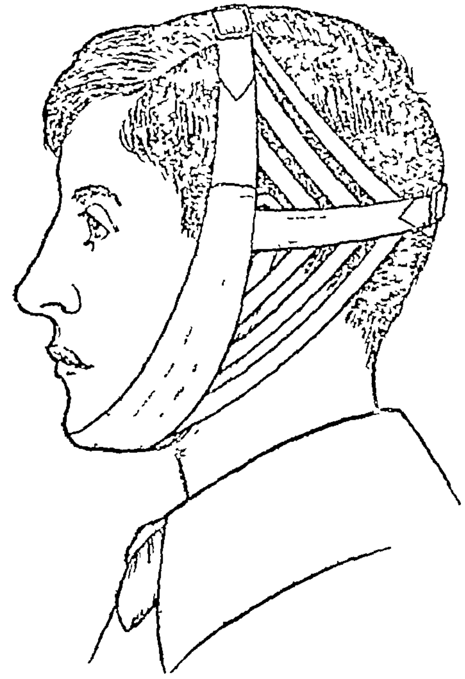
ALTHOUGH not a dentist, I am every year required to extract a very large number of carious teeth, and I have never been quite satisfied with any of the all-metal syringes for injecting local anæsthetics in these cases. I therefore asked Messrs. Allen and Hanburys, of 37, Lombard-street, London, E.C., to make one, and they have succeeded in producing what I consider to be a very perfect and efficient instrument. It is 3¼ inches in length, ¼ inch in diameter and of 30 minims' capacity. The piston is not one which is uniform in diameter throughout, but its lower inch is most accurately ground so as to fit exactly the barrel and entirely prevents any of the fluid used from "coming back" at the highest pressure required. Instead of the usual finger grips my syringe is fitted with rings for the index and middle fingers and also a ring for the thumb, as shown in the accompanying illustration, and I find practically that this is a very great improvement indeed, the operator having absolute control both as regards the pressure and the retaining of the needle firmly in its position in the gum. Moreover, it is impossible to let the instrument fall accidentally in any unusual circumstances which might occur. The needles, three in number, are of platinum iridium, about a quarter of an inch long and set in strong mounts of different shapes which screw on to the barrel of the syringe. The whole apparatus is beautifully finished and fitted in an aseptic metal case 6 inches by 2¼ inches by 1 inch, the price being 29*s*. 6*d* complete with platinum iridium needles, or 25*s*. if steel needles are supplied.



Newtownhamilton, Co. Armagh. W. J. DAWSON, M.D. Dub.

A NEW EAR AND CHIN STRAP.

THE simple apparatus which is represented in the accompanying illustration is designed to aid in overcoming the mouth-breathing habit so common in children and others who have suffered from adenoids or other nasal obstruction. Every practitioner must have experienced the difficulty of teaching these patients to breathe properly through the nose after the obstruction has been removed. The apparatus consists essentially of an elastic webbing band about two inches wide, into which the chin fits comfortably, and which tapers upwards to form a narrower elastic strap which terminates in a buckle on the top of the head. Another similar strap is inserted into this vertical one slightly above the middle and passes to the back of the head just below the occiput, where it is fastened by means of another buckle. Two pieces of fine net, or the narrow diagonal elastic bands shown in the illustration, serve to strengthen the apparatus and assist in keeping it in place on the head. It is usually only worn at night, but in the case of quite young children I often advise that it should be used also during a part, at least, of the waking hours, until the habit of breathing normally has been acquired. It is light and cool and comfortable, and produces just sufficient upward elastic pressure on the chin to make it easier to keep the mouth shut than open. Little children, I find, tolerate it well and will wear it while at play without making any attempt to displace it. It is also a very comfortable way of keeping prominent ears flat, or for holding dressings in the region of the ears in place. I use three sizes—namely, a small size for infants, a medium size for children from about five to 12 years, and a large size for adults.



The apparatus has been made for me by Messrs. Arnold and Sons, of West Smithfield, London, E.C.

Hornsey rise, N. BRYAN REYNOLDS, M.B. Lond.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING AUGUST, 1907.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1907.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cerebro-spinal meningitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including membranous croup.

farrier. Similar instances may be found on almost every page of the return.

Under such conditions as those which we have described all goes on smoothly for a time or until the mortality returns of the district show, perhaps in successive years, a remarkable prevalence of typhoid fever or of diphtheria or an infantile death-rate much in excess of the average for the county. The Local Government Board then takes note of the facts and sends down an inspector to ascertain the explanation of them. He makes a report which in the majority of cases he might make without investigation, so closely does one resemble all the rest. He finds overcrowding of dwellings upon area, overcrowding of inmates in dwellings, dwellings saturated with damp by reason of defective construction, an absence of drainage, an accumulation of fæcal matters in all sorts of places, a defective water-supply, an abundant contamination of that which exists, an absence of provision for isolating infectious disease, and a total neglect of cleanliness in dairies and slaughter-houses. These are the ordinary conditions which in each locality may be supplemented by others peculiar to itself. The report is published, is a nine days' wonder, and is forgotten, and things continue as before. There is no power anywhere to enforce the recommendations of the inspector and they are quietly ignored. Many of the reports contain references to earlier inspections of the same localities and say that the conditions then described are still existing. The medical officer of health not only has no authority but is liable to be displaced if he is what his council would describe as "troublesome," and the powers of inaction of the council are unlimited. There is probably less in rural than in urban districts of deliberate office-seeking for the express purpose of protecting nuisances and of preventing such laws as the Sale of Food and Drugs Acts from being carried into effect, but there is an amount of steady passive obstruction which only health officers themselves can realise to the full extent. In the meanwhile, the conditions of rural life are becoming as prejudicial to health as those of life in towns, and under a combination of noxious influences in both the health and the physique of the industrial sections of the community are suffering in the manner and degree recently set forth by the returns of the recruiting officers. The political exchange of votes for gabble goes on merrily, and schemers or visionaries are loud concerning projects of reform, while they leave untouched and unheeded the evils which are lying at their doors and which are certain, sooner or later, to entail due punishment upon the nation which permits their continued existence. The reform which is really needed, and which it would be the work of a true statesman to accomplish, would be to extend the protection of the laws to the thousands of poor and helpless who now suffer in health and strength from insanitary conditions which they cannot prevent and the existence of which they are frequently too ignorant either to recognise or to deplore. For this purpose the first necessity would be to give health officers security of tenure during good behaviour, to render them independent of other work, to combine districts in such a manner that needful expenditure should be spread over sufficiently large areas of taxation, and to commit, primarily to county councils and ultimately to the Local Government Board, the duty of making good the neglects and malfeasances of smaller and inferior authorities.

Membranous Colitis.

We publish this week an interesting paper by Dr. E. H. Harrisson upon Mucous Colitis, which affords a useful contribution to our present knowledge of the disease. Considerable confusion still exists in regard to the classification of diseases of the colon and there are many matters in dispute concerning their pathology. Recent researches have established the frequency with which the large intestine is the seat of disease, either primary, as in dysentery and ulcerative colitis, or secondary, as in tuberculosis, renal disease, and syphilis, while the part played by disorders of the putrefactive processes occurring in it in the genesis of various conditions of ill-health resulting from chronic constipation and stasis, though well recognised, is even yet imperfectly understood. Among the most interesting and at the same time most obscure conditions affecting the colon is that to which the names of mucous colic, muco-membranous or mucous colitis, and tubular diarrhœa have been applied. This disease has been variously regarded as an inflammatory condition—i.e., as a chronic catarrh of the mucous membrane, hence the application of the term colitis, or since, in at any rate some cases, no sign of inflammation has been discovered after death it has been regarded by Leube and Nothnagel as a neurosis of secretion, or a "myxo-neurosis," to adopt the word invented by Ewald to describe the condition. More recently it has been suggested, among others by Mr. J. P. Lockhart Mummery, that this condition has no claim to be regarded as a clinical entity, but that it is in point of fact a syndrome, or collection of associated symptoms found in a number of diseases of the colon of widely different character. In an interesting paper read before the Royal Medical and Chirurgical Society on June 11th, and published in The Lancet of June 15th, Mr. Mummery gives a careful analysis of 36 cases of disease of the colon observed by himself. He points out that owing to the application of the electric sigmoidoscope to the investigation of these cases it is possible to study directly the condition of the lower part of the colon, and by such means he has been enabled to prove the existence of local inflammatory legions in 24 out of his 36 cases. The condition most often seen was an injection of the mucous membrane with a granular appearance like that seen in granular pharyngitis. Irregular patches of whitish-yellow adherent mucous were often observed on the surface of the membrane. In seven cases there was in addition definite ulceration, the ulcers being irregular in outline and shallow with a granular base. In four cases there was a chronic hypertrophic catarrh associated with œdema of the submucous tissue, while in seven cases the cause of the colitis appeared to be the presence of cancer of the colon. Other conditions found in association with the colitis were acute pericolitis, uterine displacements, and appendicitis. Mucus was present in the stools in all the cases and in eight of them large mucous casts were passed. Mr. Mummery therefore concludes that mucous colitis is not a distinct disease and also that Nothnagel's explanation of the condition as a secretory neurosis is untenable. A study of Mr. Mummery's cases, however, shows that many of them hardly conform to the clinical type of the condition usually known as mucous colitis; moreover, the greater number of his cases were in men,

THE MEDICAL DIRECTORY.

To the Editors of THE LANCET.

SIRS,—May we be allowed through your columns to appeal to all members of the profession to return to us at once their circulars for the Medical Directory for 1908? The volume will be published about a fortnight earlier than has been customary, although the circulars were sent out a month later. It will thus be seen that the Medical Directory will be more up to date than formerly by six weeks, and in this effort, which will prove an advantage to all concerned, we rely upon the kind help always shown us by the profession.

We are, Sirs, your obedient servants,
THE EDITORS OF THE MEDICAL DIRECTORY.
7, Great Marlborough-street, London, W., Sept. 12th, 1907.

ETHER INHALATION IN PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—Your correspondent, in suggesting the use of ether inhalation for the benefit of phthisis, advances one argument as a possible justification for the measure. This argument is the fact that cases of tuberculous peritonitis have been benefited by abdominal section and that perhaps the benefit has really been due to the ether inhaled. Now in face of the fact that clinical experience with regard to the administration of anæsthetics to the subjects of pulmonary tuberculosis is very adverse to the use of that anæsthetic it seems to me that some much stronger support for the practice is needed before we recommend the ether inhalation for the benefit of phthisis. Moreover, Wright has put forward a rational and extremely probable explanation of the benefit accruing in cases of tuberculous peritonitis in which the abdomen has been opened. My own experience, and I believe it tallies with that of most anæsthetists, as it certainly does with that of such physicians as I have met in connexion with cases of operation upon phthisical subjects, is that these cases form one of the classes in which chloroform is *par excellence* the anæsthetic to be chosen in contradistinction from ether. The latter drug is much more likely to increase the activity of an active, or arouse that of a latent, tuberculous focus in the lungs. The use of chloroform inhalation for phthisis in the manner suggested by Dr. R. H Hodgson has been recommended, but I am not aware of its having been tried or, if so, with what result. Nor can I recall from my own experience cases in which the lung trouble of a patient operated upon for lesion elsewhere has obviously benefited by the chloroform administered. On the contrary, however, I could inform Dr. Hodgson of several instances where pulmonary tuberculosis has been seriously aggravated after operations performed under ether.

I am, Sirs, yours faithfully,
J. BLUMFELD.
Sept. 17th, 1907.

THE WORKMEN'S COMPENSATION ACT, 1906.

To the Editors of THE LANCET.

SIRS,—The regulations of the Secretary of State as to the duties of medical referees have been issued to them, and the profession will be pleased to hear that it will not be the fault of the medical referees under those regulations if any breach of medical etiquette should occur. On reference being made to a medical referee by a registrar of a county court the referee is instructed to give notice of the time and place of his intended examination to both the workman or his solicitor, and to the employer or his solicitor, and printed forms are supplied for this purpose, on which it is distinctly stated that any statement made or submitted by either party will be considered.

It is quite clear that the Secretary of State could not go farther than this, unless the Treasury was prepared to pay for the attendance of medical men acting in the interests of either employer or employed, which, of course, would be impossible, owing to the immense expense it would entail. Naturally it will be in the interest of both employer and the workman to place before the medical referee the fullest possible statement of the case as it appears to them, and this cannot properly be done except by a medical man. I feel quite sure that medical referees will be pleased to meet any qualified practitioner asked to attend by either employer or workman, and, in fact, by the wording of the regulation they could not refuse to do so.

The regulations also contain the following paragraph, which I think will meet with the general approval of the profession: "In cases involving special difficulty the medical referee may apply to the Secretary of State for special assistance, which may be granted by the Secretary of State, if he think fit, on such terms as to remuneration or otherwise as he may with the sanction of the Treasury determine." I am, Sirs, yours faithfully,
S. Hampstead, N.W. ALBERT BENTHALL, F.R.C.P. Edin.

ACUTE ARTHRITIS COMPLICATING OPHTHALMIA NEONATORUM.

To the Editors of THE LANCET.

SIRS,—Mr. J. H. F. Nunn's contribution on this subject as it appeared in your issue of Sept. 14th, p. 771, is certainly one of great interest, but though arthritis as a complication of ophthalmia neonatorum is very exceptional it is not quite such a rarity as Mr. Nunn's paper would seem to imply. The condition was first described by Mr. R. Clement Lucas in 1885; subsequently Mr. Lucas published an elaborate paper on the subject, together with an analysis of the records of 23 cases as collected from British and European medical literature (*Medico-Chirurgical Transactions*, vol. lxxxii.). An interesting description of the joint affections is also given in Mr. Sydney Stephenson's "Contagious Ophthalmia," and personally I communicated an example of the disease to the Society for the Study of Disease in Children in 1902 and the record of this appeared in your issue of May 31st of that year, p. 1529. The condition is thus a well-established one but it is of such rarity and interest that all concerned must be glad that Mr. Nunn has put his own personal experience on record. I am, Sirs, yours faithfully,
C. O. HAWTHORNE.
London, W., Sept. 16th, 1907.

To the Editors of THE LANCET.

SIRS,—Cases of arthritis in association with ophthalmia due to gonococci, of which Mr. J. H. F. Nunn has reported a good instance in THE LANCET of Sept. 14th, p. 771, although rare, are, of course, well known to ophthalmic surgeons. For the first observation of the kind we have to thank that acute observer, Mr. B. Clement Lucas.[1] Soon afterwards a case was reported by Dr. Johan Widmark[2] in a baby who developed ophthalmia on the sixteenth day of life, having presumably contracted the disorder from another child in the same ward. On the sixteenth day of the conjunctival inflammation the baby developed arthritis of one ankle, which subsided in something less than a fortnight under simple treatment. Widmark's communication, which was originally published in the Swedish language, will be found in that author's *Beiträge zur Ophthalmologie*, p. 95, 1891. In the same year that Lucas and Widmark wrote, another observation of the kind was published by Fendick.[3] Gonococci have been found in the affected joints by several surgeons, as Deutschmann, Hoeck, Haushalter, Heiman, Paulsen, and Altland. The infection, however, seems to be often a mixed one. While this form of gonococcal arthritis is nowadays well known I believe that arthritis in association with penumococcal ophthalmia neonatorum, of which I have seen two cases, has not yet been described.

I am, Sirs, yours faithfully,
SYDNEY STEPHENSON.
Welbeck-street, W., Sept. 14th, 1907.

ATHLETICS AND FOOD VALUES.

To the Editors of THE LANCET.

SIRS,—The existence of the British Empire depends largely upon the efficiency of the British soldier and the efficiency of the British soldier is greatly affected by the quality of his food and drink During the course of a recent walking tour among the volcanic mountains and precipices of Lappland, unsurpassed in Norway for grandeur and desolation, I was driven by necessity to certain conclusions about the best diet for marching 12 or 13 hours a day, which may possibly be of practical interest to some of your readers owing to the unusual conditions under which my observations were made.

---

[3] Brit. Med. Jour., Oct. 31st, 1885.

complaint that many inquests are held in cases where this procedure is unnecessary has often been uttered before. In the case upon which Mr. Troutbeck's observations were made a child of poor parents had been born prematurely and had died owing to the lack of such nourishment and care as in other circumstances might have saved his life. Mr. Troutbeck considered that if he had been empowered as coroner to order a post-mortem examination directly, and in this way had been able to satisfy himself that there were no evidence of neglect and no factors present in the case that called for investigation by a jury it would not have been necessary to hold an inquest. He appears to believe that in many cases expense to ratepayers, distress to relatives, and other disagreeable accompaniments of inquiries before the coroner might be avoided if the machinery provided by the Coroners Act, 1887, were better suited to its purpose. We are not impressed with this view for the reasons which seemed to influence Mr. Troutbeck in his remarks, though in certain cases there would be no harm in the increased discretion which he seeks for coroners. The particular instance which served to call his attention to a state of affairs frequently commented upon was not fortunate for his arguments. In all cases where an infant has died without a medical certificate being obtainable the slightest suspicion of neglect or of other acts on the part of adults which may have conduced to the death renders the case a desirable one for investigation at an inquest, the holding of which, even if it entails no subsequent proceedings against anyone, should have a salutary effect in warning others and in stimulating public opinion towards prevention of the present waste of infant life. Apart from this, however, the suggestions of Mr. Troutbeck and several of his colleagues are worthy of consideration and will no doubt be considered seriously whenever the law relating to death registration and the holding of inquests is consolidated and amended.

The point is a simple one. A coroner is not expected to hold inquests in all cases for which no medical man will give a certificate, nor does the granting of the certificate in any way deprive him of authority to inquire should he believe the death to be one fit for investigation. According to Section 3 of the present Act he is to hold an inquest when he "is informed that the dead body of a person is lying in his jurisdiction and there is reasonable cause to suspect that such person has died either a violent or an unnatural death or has died a sudden death of which the cause is unknown." Later in the Act he is given power to order a post-mortem examination, but this he may only do "either on his summons for the attendance of such medical witness or at any time between the issuing of that summons and the end of the inquest," there being no indication that whoever drafted the Act had any idea that a post-mortem examination might be desirable, except after an inquest had been decided upon. The contention of coroners who have a large number of deaths reported to them for which there are no certificates and who hold many inquests in the year in cases for which no one can be blamed, is that if they could order post-mortem examinations while suspending their decision as to the necessity for an inquest they might often be satisfied that the death was not one within the definition quoted above which limits their powers. We have not commented upon this definition; it may not be absolutely lucid in its wording or incapable of improvement, but it expresses fairly well that with which everyone agrees—namely, that certain deaths are not what are called popularly "natural deaths"; that when such a death may have taken place, or when, if we may amend the wording of the Act, there is "a death of which the cause is unknown," a public inquiry should place the cause of death, if possible, outside the realm of conjecture or suspicion. That there are many deaths to which the definition quoted does not apply, but with regard to which no medical man will grant a certificate, is equally agreed. A medical man, for example, practising among the poor may attend a patient and may become perfectly well aware that he is suffering from a certain complaint. The patient, however, may discontinue the services of his medical attendent, perhaps through poverty, and may die many months later, when clearly it would not be lawful that a certificate should be granted. If the coroner, then, had power to seek the opinion of the medical practitioner it would be to the effect that the cause was probably the complaint for which the deceased consulted him but that a post-mortem examination would put the matter beyond doubt. The machinery for such inquiry as that indicated would naturally include the payment of a fee to the medical man whose information enabled the coroner to arrive at his decision, and the fact that the medical man's time and trouble were given in obedience to the law and for a purpose appreciated and provided for by the legislature would do away with the friction now often caused by the informal and unauthorised questionings which are the coroner's only means of obtaining information necessary for the proper fulfilment of his duties.

While, however, we agree that the powers of the coroner should be increased by enabling him to order a post-mortem examination without binding himself to hold an inquest, and to seek from the medical man information which the medical profession alone can give in such circumstances, we have no desire to see any curtailment of the dignity or of the authority of the coroner's office. The responsibility of deciding that an inquest shall or shall not be held must still rest with him and there must be no risk of that responsibility being shifted on to the shoulders of the medical man who holds the post-mortem examination, whether he be a public official or one in private practice. It is, however, obvious that the coroner must not only be able to listen to or to read the medical man's report but must be capable of understanding it and of drawing correct conclusions if the decision arrived at is to be really his. In order to be able to give such a decision with authority the coroner must in all cases be a medical man himself additionally equipped with the legal training and experience necessary for the proper fulfilment of his duties. Under the existing law the properly trained medical man has been found to be the best and most efficient coroner. Under a system which required the holding or not holding of an inquest to depend largely upon a formal and searching inquiry and upon the proper and discriminating consideration of medical evidence a medical training should be the coroner's first and most necessary qualification.

about three-quarters of an inch in length. With the exception that the pedicle was attached to the ulnar side of the hand about the centre of the metacarpal bone the extra digit had exactly the same appearance as that of the case illustrated in The Lancet of July 20th last, reported by Dr. W. H. W. Attlee.

The history I obtained was as follows. The child's great-great-grandmother had an extra little finger on each hand. She had one child, the great-grandmother, who was born with precisely the same malformation. She also had one child, the grandfather, and he too was born with the same number of extra digits. His married life proved more prolific, for he had 12 children; of these the first, second, and third were normal, but the malformation was reproduced in the fourth child, a boy, who had a supernumerary little finger on each hand. The fifth and sixth children were again normal, but the seventh, a girl, had two extra little fingers. The eighth, ninth, tenth, and eleventh were normal, but to make up for this long rest heredity had revenge by presenting the twelfth child not only with an extra little finger on each hand but a pedunculated, supernumerary little toe on the right foot. The fourth child above mentioned is married and his eldest little girl was born with the extra digits on each hand. The eleventh child, who herself was normal at birth, is the mother of the infant brought to me.

I am, Sirs, yours faithfully,
S. H. Greene

North Kensington, Sept. 12th, 1907.

TO MEDICAL FREEMASONS.

To the Editors of The Lancet.

Sirs,—May I once again, through the medium of your widely read columns, appeal to medical men, and medical Freemasons in particular, for votes for the Masonic schools? At the forthcoming elections in October there is only one medical candidate for the *Royal Masonic Institution for Girls: Elizabeth Edith Smart*, daughter of the late Mr. H. P. Smart, M.R.C.S. Eng., of Edgbaston, Birmingham.

As there is no medical candidate for the Royal Masonic Institution for Boys votes for that institution can be exchanged and are equally valuable. Votes for either institution will be gratefully received and acknowledged by me.

I am, Sirs, yours faithfully,
Harold S. Sington,
Secretary, St. Luke's Medical Lodge
of Instruction.

Hospital for Sick Children, Great Ormond-street, W.C., Sept. 15th, 1907.

"MANSLAUGHTER IN AN ASYLUM."

To the Editors of The Lancet.

Sirs,—I wish to draw your attention to a serious misstatement in your issue of Sept. 14th under the heading of "Medical News." No such incident as that reported has occurred at the "Wonford Asylum, near Exeter."

I am, Sirs, yours faithfully,
P. Maury Deas,
Medical Superintendent.

Wonford House, Exeter, Sept. 18th, 1907.

⁂ We deeply regret the error. The information was published exactly as we received it from an experienced local correspondent who has clearly been misled.—Ed. L.

PICROTOXIN AS A PREVENTIVE OF POST-CHLOROFORM SICKNESS.

To the Editors of The Lancet.

Sirs,—I trust Dr. Peter Paterson will forgive me for pointing out that picrotoxin is not an alkaloid. In this connexion, seeing that the name of this substance ends with "in," and not "ine," I would heartily endorse Dr. Gordon Sharp's letter in your issue of August 10th, p. 410.

Yours respectfully,
W. H. Martindale.

London, W., Sept. 16th, 1907.

Hospitals and Taxation.—The committee of the South Devon and East Cornwall Hospital, Plymouth, has received a summons, which will be heard at the Guildhall, Plymouth, at 11 o'clock on Monday morning next, Sept. 23rd, for the payment of taxes on men-servants in uniform.

THE INTERNATIONAL CONGRESS OF PSYCHIATRY.

(From our own Correspondent.)

The International Congress for Psychiatry, Neurology, Psychology, and the Nursing of the Insane (to give the Congress its full name) held its annual meeting at Amsterdam from Sept. 2nd to 7th. Everything was done to start the proceedings with becoming state and solemnity. The opening ceremony was honoured by the presence of Queen Wilhelmina and her husband Prince Henry, with a staff of officers. There were delegates from the Governments of the Argentine Republic, Belgium, Brazil, Bulgaria, Chili, Denmark, France, Germany, Greece, Japan, Luxembourg, Roumania, Russia, Spain, Sweden, and the United States. There were also delegates sent by 42 scientific societies in different parts of the world. Magistrates, officers, and other dignitaries of Amsterdam increased the *éclat* of the meeting which was held in the Municipal Concert Hall, a large and beautiful building with a lofty roof, lighted from crescent windows high on the side of the walls, and having a gallery running along two-thirds of its length. A choir, composed of about 200 ladies, occupied the tiers below the great organ. The Queen sat opposite the rostrum, in a pulpit near the organ.

The Pace of Life.

The opening address, in French, was read by M. van Raalte, Minister of Justice; he was followed by Professor Jelgersma (Leyden) who discoursed upon the increasing pace of modern life as a predisposing cause of insanity. This was not a time, he said, in which it was permissible to rest. The life of to-day might be stated in two words—*répos ailleurs.* There was an overstrain in the intellectual and moral faculties which acted on the nervous system. The "feministic" movement was, he considered, an additional cause of mental derangement. Although he was ready to raise the condition of women he held that the natural difference between the sexes should not be forgotten. Women occupying the positions heretofore assigned to men were often, from their susceptibility of disposition, beset with fears and anxieties. When women entered the medical profession the condition of their patients and the fear that they should fail or had failed to understand their cases haunted them night and day. Professor Jelgersma considered that such increased activity and stress of feelings and actions were the true causes of the increase of insanity. At the end of his discourse Professor Jelgerema put the question whether the calm life of former times would ever return. The answer given was not reassuring. To our complicated life an end will never come. We must reconcile ourselves to perpetual change and perpetual progression.

It served as a kind of consolation at a depressing juncture that a chorus of rich and well-trained voices now sang the hymn of Verhulst, "God is eternal, eternal His might." This was followed by a choral singing of Handel's "Song of Triumph" from *Joshua* and the "Hallelujah Chorus" from the *Messiah*. Though the singing was very fine, there was little applause and the assembly quietly went away.

The Work of the Sections: Kurzschluss.

On Tuesday, Sept. 3rd, the work of the sections began in the University buildings. The subjects were divided into three groups: (1) psychiatry; (2) psychology; and (3) the care and nursing of the insane. The members flitted about from one room to another exchanging greetings and cards. The programmes of the day were not closely followed, it being difficult to estimate the length of the papers or of the remarks thereupon. Criticism was not frequent and the visitor to congresses is forced to conclude that in scientific, at any rate, in medical, societies debating is becoming a lost art. This is mainly owing to the large proportion of professors and teachers of medicine who attend such meetings; instead of speaking to the point they slide away into bits of old lectures. This is what the Germans call *kurzschluss*, taking the easiest way. Considering that there were 750 members enrolled the rooms were by no means crowded and towards the end of the sittings, which were held twice a day, the attendance became scanty.

Copies of many of the papers read or to be read had been already printed and were laid out for the members in a room reserved for the purpose. This was a great assistance for those who desired to know what was going on in the three

Since then the Congress of the Alpine Club of Italy has held its thirty-third meeting and before dispersing made a pilgrimage from its seat in Valsesia to the 'Angelo Mosso Institute'—again to admire the spirit that had conceived it, and the liberality and energy that had enrolled 'science,' as one of them remarked, 'among the peak-stormers.' Few events of the academic year, in truth, are more memorable than the opening of this loftiest of research stations—the characteristic supplement of twentieth century science to *hospices* of mediæval inspiration and erection, earning in a sense even more humane than the best of these the eulogy of the medical poet :—

> 'So tasked to smooth stern Winter's drifting wing,
> And garb the Eternal snows with more Eternal Spring.'
> (Temperat et boreæ rabiem mollitque pruinas,
> Et *facit* Æterno Vere tepere nives)."

WESTERN MEDICINE AND PLAGUE IN INDIA.

AN editorial article in the *Times of India* of August 24th assures us that so far as the Western portion of our dependency is concerned the old prejudice against hospital treatment is rapidly wearing away. Year by year the hospitals and dispensaries are more generally used; last year, for instance, the number of patients treated in the Bombay Presidency increased by 120,000. We are glad to know, our contemporary continues, that the Bombay Government fully realises that this increased confidence demands a corresponding improvement in the equipment of all hospitals, and especially in those of the Mofussil. Much has already been done and it is expected that before long all will be provided with the equipment necessary to enable civil surgeons to undertake operations hitherto not attempted. A good deal of hospital extension is now proceeding in Bombay and Poona and new hospitals are in course of completion at Karachi, Ahmedabad, Belgaum, and Alibagh. Three sets of x ray apparatus have been distributed and others will be supplied as funds permit. During the years of acute financial stringency Bombay hospitals suffered severely but Surgeon-General J. P. Greany, I.M.S., has set himself to the task of rehabilitation with indomitable energy and has been liberally supported by the Revenue Department. All this is pleasant reading but unfortunately in India, as elsewhere, there are two sides to every shield. "Perusal of the annual report of the Bombay Bacteriological Laboratory produces a sense of infinite depression." These are the opening words of an editorial article on another page of the same issue of the *Times of India.* The report tells us, the article goes on to say, that Haffkine's prophylactic has been brought to such perfection that wherever inoculation is practised it confers virtual immunity on the persons treated. Given a willing population it is as easy to control an outbreak of plague by inoculation as it is to combat small-pox by vaccination. These facts have been clearly established and yet people are resorting to inoculation less and less every year. The number of doses of the prophylactic issued from the laboratory last year was scarcely more than half the number demanded in 1905. The director, Lieutenant-Colonel W. B. Bannerman, I.M.S., thinks that this may be due to people holding aloof from inoculation in the hope that the Plague Commission may discover some more acceptable preventive. Our contemporary trusts that this may be the case but is not sanguine. The fear is expressed that the neglect arises from combined apathy and suspicion. The unfortunate attitude may change but there is no sign that it is likely to do so. The two articles from which we have quoted indicate a remarkable condition of things. On the one hand, we have a steadily increasing confidence in the efficacy of Western methods for combating disease; and on the other, we are confronted with a lamentable disruption of that confidence. It seems impossible to reconcile two such contradictory postulates and yet the facts are indisputable. The apparent discrepancy is due to ignorance and its offspring—suspicion. *Omne ignotum pro magnifico.* To the uneducated native of India plague is a new evil, whereas the other disabilities for the relief of which he is learning to rely upon Western knowledge have long been familiar to him. The only perfect remedy is education. Not until knowledge has become universal need we expect to meet with logical sequence in the conduct of affairs.

THE MEDICAL DEPARTMENT OF THE JOHNS HOPKINS UNIVERSITY, BALTIMORE.

THE medical department of this university is planned for the training of those who have received a liberal education, and a detailed account will be interesting to our readers just as the approach of October brings the subject of medical education closely before us. A collegiate degree in arts or science from a recognised university or college is necessary for admission. In addition to this the applicant must have a reading knowledge of French and German, with an adequate training in the preliminary scientific branches, such as chemistry, physics, and biology. The course extends over a period of four years, the term being eight months, from Oct. 1st to June 1st. The students proceed to the degree of M.D. Throughout the course special emphasis is laid on practical work in the laboratories and the hospital, which is regarded as an integral part of the medical school. In the first two years of the course anatomy, physiology, physiological chemistry, pharmacology and toxicology, pathology, and bacteriology are taken up. In the final years the hospital—both the wards and the out-patient department—is the class-room. Didactic lectures are few and instruction is given practically to small groups so far as possible. The fourth-year students spend a large part of their time working in the wards as clerks and dressers. Beginning with the session of 1907, some elective courses will be given in the final year, the student having certain freedom of choice in deciding which of the special subjects he will take. The courses for graduates are of two kinds: (1) special courses and (2) university courses. The special courses are usually given during May and June of each year to limited classes. They embrace courses in medicine (clinical work, classes in physical diagnosis, and clinical microscopy), operative surgery on animals, surgical pathology, pædiatrics, orthopædic surgery, genito-urinary surgery, x ray diagnosis, gynæcological pathology, cystoscopy, ophthalmology, and so on. These courses are practical as far as possible and are designed specially for general practitioners. The university courses differ from these in that they are given throughout the session. These are of two kinds—elementary and advanced. The former are much the same as the work being done by the undergraduates and are usually for periods of three or six months. In all of these the number who can be admitted is necessarily limited and applicants must satisfy the head of the department of their fitness to profit by the work. Thus elementary courses are given in medicine, pathology, bacteriology, physiology, gross anatomy, neurological anatomy, and physiological chemistry. For the advanced and research courses only those physicians are accepted who are prepared to undertake special studies and to spend sufficient time to make their admission worth while. Thus in medicine work may be done in the various laboratories of the medical clinic—e.g., the general clinical laboratory, the biological laboratory (which investigates biological methods of diagnosis and treatment), the physiological laboratory, and the biochemical laboratory. In the Phipp's dispensary there is a laboratory for the study of the problems of tuberculosis. In the pathological department courses on contractures in persons free from hysteria without ever being able to succeed.

Dr. **PUTNAM** (Buffalo) in an admirable paper, described five cases of Landry's Paralysis, one of Acute Infectious Multiple Neuritis, and another of Myasthenia Gravis. A striking feature in these cases was the suddenness of the onset of the paralysis.

Dr. **ERNEST JONES** (London) read a paper on the Clinical Significance of Allochiria, which is published in our present issue, *vide* p. 830.

(To be continued.)

THE SEVENTH CONGRESS OF SCANDINAVIAN SURGEONS.

(FROM OUR OWN CORRESPONDENT.)

(Concluded from p. 548.)

Dr. N. **RH. BLEGVAD** (Copenhagen) presented a report on a series of Ten Cases of Malignant New Growths treated by injections of trypsin in Professor Th. Rovsing's clinic. The result had not been encouraging as there was only one case in which the patient might possibly have derived some benefit from the treatment, the discharge becoming less profuse and foul. In one case at least increasing development of the growth set in after the injections. In another case the patient fell into a comatose state, which gradually disappeared on the discontinuance of the injections and recurred when the injections were renewed.

Dr. I. **WIDERÖE** (Christiania) read a paper on Hæmolysis as a Help to the Diagnosis of Cancer. Using Kelling's method he had tested the hæmolysis on red blood corpuscles of the hen caused by the serum of 50 patients. 25 of the cases were suffering from malignant new growths. Ten of these cases showed a hæmolysis below 30 per cent. and were reckoned as negative; 15 cases were from 30 to 85 per cent. (positive). Of the ten negative cases six were very cachectic. One patient presented decreasing hæmolysis as the cachexia increased. In another case the hæmolysis became less pronounced after complete removal of the tumour. Of the 25 patients not suffering from malignant growths only three showed a hæmolysis above 30 per cent. An investigation as to the nature of the cancer hæmolysin gave the result that it does not seem to be built up according to the "Seitenkette" (side-chain) theory of Ehrlich but is more probably related to the hæmolysin found by Bord and Kullmann in the blood of cancerous patients. The speaker considered that his observations confirmed the diagnostic value of the method.

On the third day the chief interest centred in the discussion on the Indications, Performance, and Results of Prostatectomy. Dr. G. **GUNDERSEN**, a Norwegian colleague, now in La Crosse, U.S.A., who opened the discussion, turned out to be a fervent votary of the perineal (Young's) operation, at the same time recognising the usefulness of Freyer's method. In the perineal way he had himself removed the prostate in 40 patients with good results. No patient died immediately after, or within two months from, the operation, though 14 of the cases were in an extremely bad state. All the patients became able to pass urine spontaneously *per viam naturalem* except one with a paralysed bladder. For one of the most feared complications of the operation—viz., lesion of the rectum—Dr. Gundersen had devised a simple and, as three cases of his own proved, very efficacious treatment. He introduces one blade of a scissors into the rectum and the other into the perineal wound and divides the perineum by one snip, thus creating a widely open cloaca which heals up gradually as in the operation for fistula recti. Five or six weeks later the patient is again able to pass his urine in the natural way. Of post-operative complications he had observed incontinence of urine in three of his 40 cases and in one patient an impassable (cancerous?) stricture of the urethra two years after the operation. As to the important question about the influence of the operation on sexual potency, all surgeons using Young's method were of the opinion that the overwhelming majority of the patients kept what they might possess of potency before the operation. Dr. Gundersen thought that the indications for prostatectomy ought to be considered on a broader basis than had hitherto been usual and he felt sure that this treatment was superior to all former methods.

Dr. **JERVELL** (Christiania) thought that any case of prostatic enlargement causing symptoms should be kept under observation by the surgeon. If the quantity of residual urine increased or the tumour continued to grow an operation should be carried out, preferentially, if the patient could stand it, a prostatectomy. He had mostly used Freyer's method and though his own results were not brilliant he should go on using it.

Professor **THORKILD ROVSING** (Copenhagen) first wished to protest against a statement which had been made that vasectomy had been abandoned as a treatment of enlarged prostate because it had proved inefficacious. In reality the operation had, like castration, been abandoned because it was "mutilating" and created impotence. He alone had thoroughly tried vasectomy and laid down definite indications for its performance—viz, the uniform soft enlargement of the prostate, while it did not help in the hard hypertrophies. Acting on these indications he had attained very satisfactory results. Amongst 82 vasectomies he had 49 cured, 25 improved, and no deaths. As to the mortality of prostatectomy Gundersen's and Young's results must be admired. But most other operators had rather a high mortality, so that it must generally be considered as a somewhat dangerous operation. If really, however, a complete cure could be promised to all patients who survived the operation, he could understand the enthusiasm of the prostatectomists, even if he could not share it. But such a promise could not, and ought not, to be given. Not seldom retention of the urine remained as before the operation; perineal fistulæ and strictures of the urethra were not infrequent. It was impossible to foresee how the seemingly cured patients would fare later. It was scarcely possible that they should not in many cases develop stricture of the urethra, considering the often inevitable great lesions of that canal. He had himself performed 11 partial prostatectomies, in two of which the patients died, while four were cured and five were not improved. Of his nine total prostatectomies six were suprapubic (with one death) and three were perineal (with two deaths). In one of the suprapubic cases a very dangerous hæmorrhage occurred on the twelfth day after the operation, the patient being only saved by a complete plugging of the bladder. One patient returned a few months after the operation with complete retention produced by stricture of the urethra. The most serious objection to the operation was, however, the fact that in a great number of cases the retention remained unchanged, especially when the enlargement of the gland and the retention were comparatively little pronounced before the operation. It interested him to notice that Gundersen and Young's school had given up their former opinion that partial prostatectomy was to be rejected. Dr. Gundersen now emphasised that only the diseased parts of the prostate should be removed. The reason for this changing of opinion, in which as yet Freyer did not seem to have joined, was that at length the prostatectomists had begun to become aware of the important physiological function of the prostate to which he (Professor Rovsing) had drawn attention already in 1902 and later in Brussels in 1905. It was highly to be regretted that the promoters of prostatectomy had removed hundreds of prostates, not only from old men but from men 40 and 50 years of age, without heeding the importance of the gland for the sexual functions, not knowing that the removal of the prostate produced not only impotence just as surely as a castration did but far oftener than a castration serious psychical derangements followed by suicide. This being so, was there any reason to lay down as a routine treatment of the enlarged prostate this dangerous operation, which, though removing an organ of the highest importance, did not always satisfy the only existing indication—viz., to do away with the retention? Was it not much wiser to have recourse to an operation which did always help the patient and was practically devoid of danger? He had excellent results in suprapubic cystostomy, performed without narcosis, 115 cases with two deaths, two patients with pulmonary affections who insisted on being placed under an anæsthetic notwithstanding advice to the contrary. Once the immediate danger was passed and the retention was done away with, the performance of a prostatectomy might be considered if the patient did not feel content with his state after the cystostomy. Professor Rovsing only performed primary suprapubic prostatectomy in those cases in which a beak-like elongation of the prostate into the bladder prevented the introduction of a catheter, some telephone or telegraph cables. We see no reason why this work should not be carried on by a night shift as well as by a day shift, but there is some weird influence about roads which appears to make those responsible for their upkeep absolutely indifferent to the convenience of those who use them, to the pockets of the ratepayers, and to the sufferings of the unfortunate animals.

THE GOVERNMENT AND RESEARCH.

THE President of the Local Government Board has authorised the following researches under the grant voted by Parliament in aid of scientific investigation concerning the causes and processes of disease: 1. Further study by Dr. Sidney Martin, F.R.S., of the chemical products of pathogenic bacteria. 2. Bacteriological investigation by Dr. F. W. Andrewes of the air of sewers and drains. 3. Observation by Dr. W. G. Savage of the bacteriology of "garget" and maladies of the udder or teats of milch cows; and of the possible relation of sore-throat in the human subject to pathological conditions of the udder and teats of these animals. Also investigation by him of paratyphoid fever and its microbic cause. 4. Joint investigation by Dr. M. H. Gordon and Dr. T. J. Horder of the life processes of the meningococcus with a view to means of combating cerebro-spinal fever.

THE HYGIENE OF SCHOOL LIFE IN THE UNITED STATES.

Dr. Richard Cole Newton of Montclair, New Jersey, communicated to the section on hygiene and sanitary science of the American Medical Association at the last annual meeting an interesting paper on the Attitude of the Medical Profession toward the Hygiene of School Life.[1] *Dr. Newton* referred to the International Congress of School Hygiene, saying that it would be for the good of the race in the United States if such a conference were to be held in that country where, he averred, the present system of public instruction is constantly defeating its own ends and turning out invalids, cranks, and "bookful blockheads ignorantly read," simply for the want of a well-balanced curriculum of instruction which accords an appropriate place to physical education. Dr. Newton allows that excellent work in the direction of school hygiene has been accomplished in Chicago, Boston, and in other American cities, which makes it all the more regrettable that there is no scheme for amalgamating and systematising the work. Medical inspection of school children is fairly general in the United States and has received the unqualified approbation of the teachers who desire its extension, so that here at any rate an excellent start has been made, but other problems which trouble us in England are also presenting themselves across the Atlantic. The question of giving free breakfasts to poor school children leads Dr. Newton to point out that, so far as New York is concerned, an investigation by the board of health has disclosed the fact that some children went to school breakfastless, not because no food was provided but because they could not eat after the night spent in their ill-ventilated and overcrowded tenements. The Committee on the Physical Welfare of School Children also found that only 1·1 per cent. of 1500 New York children whose cases were investigated were not provided with some breakfast. Dr. Newton expressed the opinion that in order to provide the proper sort of physical instruction to school children a special class of *medical* men must be raised up, and here he went over much the same ground as was recently traversed by Dr. Nicholas Senn in the Jerome Cochan lecture recently delivered before the Medical Association of the State of Alabama. In this lecture the well-known American surgeon advocated the foundation of hygienic institutes "where young medical men can receive the necessary education and training to prepare themselves for the high and responsible office of sanitary or health commissioner in the different communities." Dr. Newton thought that a somewhat larger scope should be given to such institutes so that they might turn out the properly qualified director and instructor in the public and private schools. He proposed that a commission should be appointed in the United States which should have control over all matters connecting physical with scholastic instruction. In many respects the school children of the United States are better cared for from a physical standpoint than they are in this country. Medical inspection of school children is more or less the rule, and the principles of hygiene are taught in many of the schools. In New York City, for example, hygiene and elementary physiology have been taught in the public schools for some time. The flaw in the American system seems to be its lack of uniformity; in some States the methods of school medical inspection and teaching of hygiene are good, while in other States these methods are conspicuous by their absence. It is somewhat amusing, however flattering it may be to our self-esteem, that England should be quoted as a nation careful of the physical well-being of her poor school children. A new leaf has been turned now, but in the past perhaps nowhere in the world was the health of indigent young children more neglected than in England.

EXPERIMENTAL ANÆMIA.

ALTHOUGH the clinical features of the various forms of anæmia are well defined their pathology still remains obscure. In the *Journal of the American Medical Association* of August 10th Dr. C. H. Bunting has published an instructive paper on experimental anæmia which throws much light on the subject. By injecting large doses of ricin or saponin into the veins of dogs and rabbits he produced a progressive anæmia and condition of blood exactly resembling that of pernicious anæmia. In rabbits, nucleated red cells, both megaloblastic and normoblastic, and characteristic changes in the non-nucleated cells (variation in size with a predominance of those above the average, poikilocytosis, polychromatophilia, granular basophilia, and an increased colour index) are produced. Even the leucopenia with relative increase of mononuclears may occur. In short, none of the features of pernicious anæmia are lacking. Moreover, a condition of bone marrow similar to that of pernicious anæmia may be produced—predominance of megaloblastic type of nucleated cells and of cells of the large lymphocyte type. The animals react with machine-like regularity to the poison. Each injection is followed by the production of nucleated cells and a fall in the number of red cells and their gradual assumption of the abnormalities mentioned above. This reaction is entirely different from that produced in animals by repeated hæmorrhage—a fall in the number of red cells without production of nucleated red cells. Megaloblasts are not found in the blood and normoblasts only occasionally. The colour index falls rapidly, the corpuscles become very pale, and the marrow shows the appearances characteristic of secondary anæmia, nucleated cells of the normoblastic type predominating. If the hæmolytic substances are injected not intravenously but subcutaneously or intraperitoneally the result is different. Hæmolysis is produced, blood pigment is deposited in the spleen, and the number of red cells is reduced, but the sharp nucleated-cell reaction does not occur in the blood, the fall in the number of red cells is less sharp, and the marrow shows the appearances of a secondary anæmia with characteristic predominance of normoblastic cells. Dr. Bunting *thinks* that

---

[1] Journal of the American Medical Association, August 24th, 1907.

Mussen (assistant medical officer of health). A repast was served in the administrative block of the new Fazakerley Hospital, Mr. John Utting presiding and giving the loyal toasts and "The Lord Mayor." The Lord Mayor, responding to the toast of his health, remarked that during the ten months in which he had experienced the pleasure of being Lord Mayor of Liverpool he had abstained from joining in the debates of the city council, as he conceived it to be his duty, as a rule, to leave the council to do its own business without his interposition. He had, however, felt strongly inclined to take part in the discussion at the previous meeting of the council when a vote of £50 annually to Dr. William Hanna for services at the New Ferry Hospital was under discussion. He saw that the council in large part failed to grasp the question at issue and to realise the importance of the work intrusted to Dr. Hanna. As a shipowner he could imagine what might be the loss to Liverpool if a bad bill of health led ships from the port of Liverpool to be placed in quarantine at foreign ports. The maintenance of a clean bill of health for this port depended chiefly on the medical inspection of the incoming vessels, and of the 350,000 transmigrants who yearly passed through Liverpool. Hence the port sanitary work of the committee, as well as its city hospital work, was of a most important character and ought not be under-estimated by the city council. Mr. John Utting (the chairman of the committee), in acknowledging the toast of his health, thanked the Lord Mayor for placing the question of Dr. Hanna's salary in its true light, and emphasised both the commercial and sanitary aspects of the work of protecting the health of the port, which was not less important than the safeguarding of the health of the city as a whole. What would happen were Liverpool to become a prey to cholera, as Hamburg had been? If a single case of cholera or plague escaped detection the results would be disastrous. The commercial prosperity of Liverpool would receive a severe, and it might be a permanent, check, while the loss of life might be incalculable. It was with great pleasure that he found that the Lord Mayor had so clear a grasp of the value of Dr. Hanna's services At times it seemed a pity that the committee had dual duties, some people looking upon it merely as a committee subsidiary to the health committee and others thinking that the committee confined its attentions to the infectious hospitals. He was glad that the city council eventually realised that the committee was in the right on the question of the special remuneration to Dr. Hanna and did not do him the injustice threatened by the council vote last month. Passing to the city hospitals, he reminded the committee that the city council at the beginning of the financial year reduced its careful estimate by £10,000. The council reduced the resources of the committee but it did not reduce the committee's responsibilities, which were actually increased by extended operations, though the average of sickness was less than usual. Curiously enough, but suggestive, the decrease of infectious disease was only in the forms for which hospital accommodation was provided and the time was not far distant when resources not expended in one direction would have to be diverted to the reduction of other infectious diseases. The medical examination of school children carried on for the past eight months to trace the causes of disease showed that out of 6000 children only 7 per cent. were affected with scarlet fever (isolated in hospitals), which was formerly the most prevalent disease, while measles and whooping cough (not isolated in hospitals) accounted for from 60 to 70 per cent. of the cases. The moral was that many cases of measles and whooping-cough must go to the isolation hospitals. Some inconsiderate people thought that empty or partially empty hospitals denoted extravagance and failure. To have the hospitals empty was a consummation devoutly to be wished and was a sign of success.

Education Committee Appointment.

The secondary education subcommittee of the education committee has appointed Dr. F. E. S. Jeans as lecturer on hygiene for the evening classes for students preparing for the certificate examination at the Oulton Secondary School and pupil teachers' centre in succession to Dr. Robert E. Kelly, surgical registrar to the Royal Infirmary, resigned.

The Order of the Hospital of St. John of Jerusalem.

In recognition of the services rendered by Mr. Arthur J. Evans, M.R.C.S. Eng., L.R.C.P. Lond., of Liverpool, subsequently to the disastrous earthquake in Jamaica on Jan. 14th last, the Order of the Hospital of St. John of Jerusalem in England has been conferred on him by the Grand Priory of that Order.

Sept. 17th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Resignation of Professor C. J. Wright.

BY the resignation of Professor Wright one of the oldest links of union between the original medical school of Leeds and the modern University is broken. It is given to few men to serve any institution for so long as Professor Wright has. Loyally and untiringly he has consistently done his work and has always had before him the high ideal of maintaining and increasing the reputation of the medical school. Professor Wright's resignation was accepted with great regret by the Council of the University and at a recent meeting of the Board of the Faculty of Medicine the following resolution was unanimously passed and transmitted to Professor Wright:—

> The board has heard with regret that Mr. Wright has resigned the professorship of midwifery after forty years of faithful work in the interests successively of the Leeds School of Medicine, the medical department of the Yorkshire College, and the School of Medicine of the University of Leeds. For two years Mr. Wright was assistant demonstrator in anatomy, then for fourteen years lecturer on physiology, and for twenty-four years he rendered service in the department of midwifery, first as lecturer and later as professor. Mr. Wright held office as secretary of the council of the Leeds School of Medicine from 1878 to 1880, when he became the president for the year. Since the foundation of the University he has been one of the representatives of the joint faculties on the Court of Governors. He has always been an assiduous and conscientious attendant at board and University meetings. The board desire to record their sense of obligation to Mr. Wright for his long and sincere service, of which they will always retain a lively recollection.

The Open Air Swimming Bath at Roundhay Park.

The provision for Leeds of an open-air swimming pool, which was mentioned in this column on Feb. 16th of this year, has been happily accomplished and the bath is in every way a great success and has been very largely used in spite of the somewhat inclement nature of the summer. The dimensions of the bath are 150 feet in length by 60 in width, and the depth varies from 3 to 5 feet. The bottom and sides are cemented throughout and there is a continuous flow of water through the bath which is provided by the overflow from the Waterloo Lake and can be varied in amount as required. The bath is provided with about 40 dressing boxes, is well surrounded by trees, and is in every way a most satisfactory addition to the bathing facilities of the city. The work was in large measure carried out by men from the corporation Unemployed Registry Office and it is satisfactory to learn that the experiment of employing these men is regarded by the committee as encouraging.

Sept. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Infirmary and St. Mungo's College, Glasgow.

A CONFERENCE between the managers of the Royal Infirmary and the governors of St. Mungo's College was held last week to consider the present position of the college. At the meeting reports were submitted from a joint committee representing St. Mungo's College and the Royal Infirmary in reference to the relations between the two bodies in the matter of medical teaching. After discussion it was found that no common basis of agreement could be arrived at and the meeting was adjourned *sine die*. St Mungo's College was originally brought into existence by the managers of the Royal Infirmary chiefly to carry on the medical school of the infirmary and to be in a position to take advantage of the affiliation clauses of the 1889 Universities (Scotland) Act, as only an incorporated college could become affiliated to a university, and the infirmary managers could not as a board become incorporated as a college. The infirmary managers made over to the college their medical school buildings in the grounds of the Royal Infirmary, which had been erected a few years previously by public subscription. Two of the chairs at the college are partially endowed, one lectureship is fully endowed, and the college possesses some funds in strength of the legs was good. The heart was normal. He showed the same difficulty in starting and in progressing as was present in the previous case. In the third case the patient was a man, aged 72 years, who for some time had suffered from increasing difficulty in locomotion, especially in starting, and a tendency to shorten his steps more and more as he progressed. After going a few yards he was often obliged to stop from exhaustion. The heart sounds were weak and the radial arteries were much sclerosed. The knee-jerks were active. The pathology of such cases is obscure. In an exhaustive article on the disturbances of gait in the aged Petrén described this gait and attributed it to cerebral arterio-sclerosis. He thinks this produces a subjective feeling of difficulty of locomotion which causes the incapacity. This view is in keeping with the fact that by encouragement and instruction it is not difficult to induce the patients to walk with comparative ease.

THE AUSTRALASIAN MEDICAL CONGRESS.

THE eighth session of the Australasian Medical Congress will be held in Melbourne in 1908 under the presidency of Professor H. B. Allen, of the University of Melbourne, from Oct. 19th to 24th. The subscription is one guinea and will entitle every member to a copy of the Transactions of the Congress. The council of the University of Melbourne has granted the use of its buildings. The Government of Victoria has undertaken the printing of the Transactions. Addresses will be given in full congress by the presidents of the sections of medicine, surgery, pathology and bacteriology, and public health. Special meetings of the congress will be devoted to the following subjects: (1) the relations of the medical profession to hospitals; (2) syphilis. The work of the congress will be divided into the following 11 sections—namely, (1) medicine; (2) surgery; (3) obstetrics and gynæcology; (4) anatomy and physiology (with experimental pharmacology); (5) pathology and bacteriology; (6) public health and State medicine; (7) diseases of the eye, ear, and throat; (8) neurology and psychiatry; (9) diseases of children; (10) naval and military medicine and surgery; and (11) diseases of the skin, radiotherapy, and radiography. The general secretary is Dr. H. C. Maudsley, 8, Collins-street, Melbourne.

ANTIDIPHTHERIAL SERUM AND DIPHTHERIAL PARALYSIS.

SOME divergence of opinion has existed as to the relationship between the use of antidiphtherial serum and the occurrence of paralysis after the disease. When antitoxin was first introduced it was noted that the percentage of cases in which paralysis occurred was apparently *increased*, and there was some tendency to blame the new remedy for this sequel. It was, however, pointed out that the apparent increase in cases of paralysis was explicable on the ground that many severe cases of diphtheria which would have died in olden days were now saved by the antitoxin and lived to suffer from some degree of paralysis instead of dying outright. It has even been maintained by Comby that antitoxin, far from causing the paralysis, is actually a remedy of value even after this condition has supervened, and there is little doubt that early recourse to the remedy reduces the liability to subsequent affection of the nerves. Some recent experiments by Dr. M. J. Rosenau and Dr. J. F. Anderson, carried out in the Hygienic Laboratory of the United States Public Health Service,[1] throw further light upon the question. It seems that the guinea-pig suffers from a form of paralysis caused by the toxin of diphtheria which is almost exactly similar to that seen in mankind. In this animal a small dose of antitoxin given at the time of infection, or before it, suffices to prevent the occurrence of paralysis, but if 48 hours are allowed to elapse before it is administered then the remedy has no effect, nor can it influence the paralysis when it has actually developed. This is after all what might be expected, for the occurrence of paralysis depends upon degenerative changes in the nerve-fibres, a condition which is clearly beyond the reach of any antitoxic remedy. It may, however, still be argued that if antitoxin has not already been administered it would be well to give a dose even when the paralysis has appeared in order to neutralise any toxin which may still be circulating in the blood and which may aggravate the nervous lesion. Experience alone can decide how long any toxin may remain in the system unneutralised; but we expect that in most cases by the time paralysis has occurred the toxin has done its work and disappeared.

EPIDEMIC CEREBRO-SPINAL FEVER.

IN London during the month of August there were 13 cases of epidemic cerebro-spinal fever notified, of which two each belonged to Shoreditch, Bethnal Green, Stepney, and Camberwell, and one to each of five other boroughs. In Scotland during the week ended Sept. 14th there were ten deaths from this cause registered in Glasgow, six in Edinburgh, and two in Dundee. In Glasgow the weekly report issued on Sept. 13th showed that there were at that time 29 cases under treatment. In Belfast during the week ended Sept. 14th there were five deaths registered as being due to this cause.

THE Department of Public Health of Queensland in a bulletin dated August 10th states that no case of plague has occurred in Brisbane since July 20th. As regards the Mauritius, a telegram from the Governor received at the Colonial Office on Sept. 13th states that for the week ending Sept. 12th there were 11 cases of plague and 11 deaths from the disease.

THE second Norman Kerr lecture of the Society for the Study of Inebriety will be delivered in the hall of the Royal Society of Medicine, 20, Hanover-square, London, W., on Tuesday, Oct. 8th, at 8.30 P.M., by Dr. R. W. Branthwaite, H.M. Inspector under the Inebriates Act. The subject is "Inebriety, its Causation and Control."

Dr. D. C. McVail has been reappointed member of the General Medical Council representing the Crown for Scotland.

NOTES UPON HEALTH RESORTS.

THE WATER-SUPPLY OF AIX-LES-BAINS (SAVOIE).

THE remarkable development of Aix-les-Bains as a thermal station during the last quarter of a century and the enhanced requirements for potable water have rendered it absolutely necessary to seek to add to existing supplies. A scheme has been elaborated by the municipality to obtain the additional supply from Lake Bourget and in these circumstances it appeared to us desirable to make an independent examination of the lake water under conditions as similar as possible to those adopted by the authorities in respect of date, depth, and site of collection of samples. In justification of this step we may point out that Aix-les-Bains is one of the most popular watering-places on the continent and is *frequented* by very large numbers of English and American visitors, some of whom go there in order to benefit by the thermal treatment and others in order to enjoy the amusements offered by the casinos and similar places of *entertainment*, whilst many are attracted by the natural beauties of this land of mountains and lakes. Inasmuch as the health of this

---

[1] Rosenau and Anderson: Bulletin No. 38, U.S. Public Health and Marine-Hospital Service. Washington, 1907.

Mussen (assistant medical officer of health). A repast was served in the administrative block of the new Fazakerley Hospital, Mr. John Utting presiding and giving the loyal toasts and "The Lord Mayor." The Lord Mayor, responding to the toast of his health, remarked that during the ten months in which he had experienced the pleasure of being Lord Mayor of Liverpool he had abstained from joining in the debates of the city council, as he conceived it to be his duty, as a rule, to leave the council to do its own business without his interposition. He had, however, felt strongly inclined to take part in the discussion at the previous meeting of the council when a vote of £50 annually to Dr. William Hanna for services at the New Ferry Hospital was under discussion. He saw that the council in large part failed to grasp the question at issue and to realise the importance of the work intrusted to Dr. Hanna. As a shipowner he could imagine what might be the loss to Liverpool if a bad bill of health led ships from the port of Liverpool to be placed in quarantine at foreign ports. The maintenance of a clean bill of health for this port depended chiefly on the medical inspection of the incoming vessels, and of the 350,000 transmigrants who yearly passed through Liverpool. Hence the port sanitary work of the committee, as well as its city hospital work, was of a most important character and ought not be under-estimated by the city council. Mr. John Utting (the chairman of the committee), in acknowledging the toast of his health, thanked the Lord Mayor for placing the question of Dr. Hanna's salary in its true light, and emphasised both the commercial and sanitary aspects of the work of protecting the health of the port, which was not less important than the safeguarding of the health of the city as a whole. What would happen were Liverpool to become a prey to cholera, as Hamburg had been? If a single case of cholera or plague escaped detection the results would be disastrous. The commercial prosperity of Liverpool would receive a severe, and it might be a permanent, check, while the loss of life might be incalculable. It was with great pleasure that he found that the Lord Mayor had so clear a grasp of the value of Dr. Hanna's services At times it seemed a pity that the committee had dual duties, some people looking upon it merely as a committee subsidiary to the health committee and others thinking that the committee confined its attentions to the infectious hospitals. He was glad that the city council eventually realised that the committee was in the right on the question of the special remuneration to Dr. Hanna and did not do him the injustice threatened by the council vote last month. Passing to the city hospitals, he reminded the committee that the city council at the beginning of the financial year reduced its careful estimate by £10,000. The council reduced the resources of the committee but it did not reduce the committee's responsibilities, which were actually increased by extended operations, though the average of sickness was less than usual. Curiously enough, but suggestive, the decrease of infectious disease was only in the forms for which hospital accommodation was provided and the time was not far distant when resources not expended in one direction would have to be diverted to the reduction of other infectious diseases. The medical examination of school children carried on for the past eight months to trace the causes of disease showed that out of 6000 children only 7 per cent. were affected with scarlet fever (isolated in hospitals), which was formerly the most-prevalent disease, while measles and whooping cough (not isolated in hospitals) accounted for from 60 to 70 per cent. of the cases. The moral was that many cases of measles and whooping-cough must go to the isolation hospitals. Some inconsiderate people thought that empty or partially empty hospitals denoted extravagance and failure. To have the hospitals empty was a consummation devoutly to be wished and was a sign of success.

Education Committee Appointment.

The secondary education subcommittee of the education committee has appointed Dr. F. E. S. Jeans as lecturer on hygiene for the evening classes for students preparing for the certificate examination at the Oulton Secondary School and pupil teachers' centre in succession to Dr. Robert E. Kelly, surgical registrar to the Royal Infirmary, resigned.

The Order of the Hospital of St. John of Jerusalem.

In recognition of the services rendered by Mr. Arthur J. Evans, M.R C S. Eng., L.R C.P. Lond., of Liverpool, subsequently to the disastrous earthquake in Jamaica on Jan. 14th last, the Order of the Hospital of St. John of Jerusalem in England has been conferred on him by the Grand Priory of that Order.

Sept. 17th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Resignation of Professor C. J. Wright.

BY the resignation of Professor Wright one of the oldest links of union between the original medical school of Leeds and the modern University is broken. It is given to few men to serve any institution for so long as Professor Wright has. Loyally and untiringly he has consistently done his work and has always had before him the high ideal of maintaining and increasing the reputation of the medical school. Professor Wright's resignation was accepted with great regret by the Council of the University and at a recent meeting of the Board of the Faculty of Medicine the following resolution was unanimously passed and transmitted to Professor Wright:—

> The board has heard with regret that Mr. Wright has resigned the professorship of midwifery after forty years of faithful work in the interests successively of the Leeds School of Medicine, the medical department of the Yorkshire College, and the School of Medicine of the University of Leeds. For two years Mr. Wright was assistant demonstrator in anatomy, then for fourteen years lecturer on physiology, and for twenty-four years he rendered service in the department of midwifery, first as lecturer and later as professor. Mr. Wright held office as secretary of the council of the Leeds School of Medicine from 1878 to 1880, when he became the president for the year. Since the foundation of the University he has been one of the representatives of the joint faculties on the Court of Governors. He has always been an assiduous and conscientious attendant at board and University meetings. The board desire to record their sense of obligation to Mr. Wright for his long and sincere service, of which they will always retain a lively recollection.

The Open Air Swimming Bath at Roundhay Park.

The provision for Leeds of an open-air swimming pool, which was mentioned in this column on Feb. 16th of this year, has been happily accomplished and the bath is in every way a great success and has been very largely used in spite of the somewhat inclement nature of the summer. The dimensions of the bath are 150 feet in length by 60 in width, and the depth varies from 3 to 5 feet. The bottom and sides are cemented throughout and there is a continuous flow of water through the bath which is provided by the overflow from the Waterloo Lake and can be varied in amount as required. The bath is provided with about 40 dressing boxes, is well surrounded by trees, and is in every way a most satisfactory addition to the bathing facilities of the city. The work was in large measure carried out by men from the corporation Unemployed Registry Office and it is satisfactory to learn that the experiment of employing these men is regarded by the committee as encouraging.

Sept. 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Infirmary and St. Mungo's College, Glasgow.

A CONFERENCE between the managers of the Royal Infirmary and the governors of St. Mungo's College was held last week to consider the present position of the college. At the meeting reports were submitted from a joint committee representing St. Mungo's College and the Royal Infirmary in reference to the relations between the two bodies in the matter of medical teaching. After discussion it was found that no common basis of agreement could be arrived at and the meeting was adjourned *sine die.* St Mungo's College was originally brought into existence by the managers of the Royal Infirmary chiefly to carry on the medical school of the infirmary and to be in a position to take advantage of the affiliation clauses of the 1889 Universities (Scotland) Act, as only an incorporated college could become affiliated to a university, and the infirmary managers could not as a board become incorporated as a college. The infirmary managers made over to the college their medical school buildings in the grounds of the Royal Infirmary, which had been erected a few years previously by public subscription. Two of the chairs at the college are partis endowed, one lectureship is fully endowed, and th taken in conformity with his detailed directions (adding one cubic centimetre of chloroform per litre in order to prevent any further nitrification in transport), and the samples taken on June 28th, 1896, gave an average of 1·48 milligrammes of nitrogen in nitrates per litre. The scheme adopted by the municipality provides for the captation of water at a spot (see map) about 360 metres from the lake shore, between the Grand Port and the Cap de l'Ardre—that is to say, at a spot which is not in proximity to any source of contamination such for instance, as the inlet of a stream or river. This part of the shore consists of coarse sand and pebbles and runs down at a gentle slope into the lake to within a few yards of the captation spot which is over a subaqueous precipice. The water at this spot is so clear that it is possible to see the bottom even at a great depth. It follows that there is little hindrance to the penetration of the sun's rays which, as is well known, exert a powerful purifying action on water. It is proposed to take 4400 cubic metres daily from the lake and to pump it through underground pipes across an inhabited area to a reservoir to be constructed on the heights of Corsuet where, as an additional precaution, it is to be filtered through gravel and sand before being distributed. This reservoir will have a capacity of 4400 cubic metres, equal to half a day's supply. The deep aperture of the intake pipe will project over a ledge in the bottom of the lake and will be secured by a metal frame-work at a sufficient distance from the side to avoid stirring up mud, of which in any case there can be but little in view of the sharp declivity.

In an excellent synopsis of his researches into available water-supplies in the district of Chambéry, which includes that of Aix-les-Bains, Professor Hollande, D.Sc., gives much practical information based on direct observation of the value of lake waters in respect of their use for domestic purposes.[3] He points out that lake water is invariably softer than the water brought to it by the various tributaries except, perhaps, in the case of certain very small collections such as the neighbouring lakes of St. Hélène, St. André, des Pères, &c., the waters of which are stagnant. Lake Bourget, on the other hand, is the largest of French lakes and the water taken from the western shore—that is to say, on the side opposite Aix-les-Bains—is a good potable water.

In regard to bacteriological examination this water was found to contain 150 aerobic germs per cubic centimetre, the count having been made on the twentieth day after inoculation. These consisted of the micrococcus aquatilis, bacillus flavus liquefaciens, and the bacterium termo. Search for various pathogenic organisms proved negative.

The samples for chemical analysis were collected in December, 1906, in glass receptacles previously heated to redness and emptied of air by the air-pump. These were let down to the measured depth and allowed to fill *secundum artem*. They were hermetically sealed on being withdrawn and carefully packed for despatch to London. The site of collection was 350 metres from the lake shore between the Grand Port and the promontory of St. Innocent, the temperature at the time being 0°C. The temperature at the various depths was as follows:—At one metre, 5° C.; at five metres, 7°C.; at ten metres, 10°C.; at 15 metres, 10°C.; at 20 metres, 10°C.; and at 25 metres, 9·9°C.

As shown by the accompanying table of analytical results the differences found at various depths are hardly appreciable, but the evidence, on the whole, is slightly in favour of the deeper samples. Curiously enough the best sample of all is that taken from the intermediate depth of ten metres. All the samples of water were quite limpid, bright, bluish in tint, and free from odour. All proved to be decidedly soft, but owing to a small amount of lime salts which comprise the total solids they are without action on lead. There is not the slightest evidence of pollution and not the slightest trace of the presence of organic matter derived from the soil, search for albuminoid ammonia giving in every instance an absolutely negative result, while the free ammonia practically amounted to nothing in the case of the water taken from a depth of five metres. The water taken from a depth of 15 metres shows the same freedom from organic impurity as that of Loch Katrine in Scotland, with the advantage that it contains a somewhat larger proportion of mineral salts which prevent any action on lead pipes. We need hardly point out that a water of this very pure description needs, of course, to be jealously guarded against contamination, since pathogenic germs are peculiarly prone to multiply very rapidly in such waters.

Analysis of Waters taken at Different Depths from Lake Bourget, Aix-les-Bains.—Parts per 100,000.

Depth.	Appearance.	Free ammonia.	Albuminoid ammonia.	Chlorine in chlorides.	Common salt.	Nitrogen in nitrates.	Total solids.
1 metre.	Bright and clear.	*Nil.*	*Nil.*	1·00	1·65	0·040	18·00
5 metres.	"	0·005	"	0·70	1·15	0·040	16·00
10 metres.	"	*Nil.*	"	0·40	0·66	0·030	15·00
15 metres.	"	0·005	"	0·600	0·930	0·032	16·00
20 metres.	"	*Nil.*	"	0·700	1·150	0·032	16·00

The sample taken at 25 metres was lost through breakage of the flask in transit. The waters contain lime salts chiefly irremoveable by boiling. The total solids practically consisted of lime salts.

MICRO ORGANISMS IN LAKE WATER.

The subject has been very thoroughly investigated by various observers and it may be well to refer to the results obtained by them in order to afford a ground for comparison. Frankland in his work on "Micro-organisms in Water" points out that the water of Lac Leman at Geneva proved to contain as many as 150,000 organisms per cubic centimetre near the shore, whereas water taken from the middle of the lake only contained 38. These results were confirmed by Karlinski. In the Borke lake, near Konjca, in Herzegovina, water from the surface of the lake, at a distance of 200 metres from the shore, yielded 4000 organisms per cubic centimetre, while close to the shore, in the vicinity of the reeds, they numbered 16,000. The observer also examined the water at various depths and discovered great differences in respect of the abundance of micro-organic life. These examinations were conducted anaerobically as well, so that the maximum number of organisms would thus be detected. While on the surface each cubic centimetre contained 4000, at a depth of only five metres the number fell to 1000; at ten metres rarely more than 600; and at still lower depths, from 12 to 16 metres, only between 200 and 300 per cubic centimetre were found. At the bottom of the lake when the mud was stirred up the proportion rose to 6000. These figures represent the average of some 60 observations.

Cremer gave as the result of 50 examinations of the water of the Lake of Zürich an average of between 42 and 71 organisms per cubic centimetre according to the time of the year, the proportion being higher during the winter. The water of Lucerne gave from 8 to 51 organisms per cubic centimetre, the latter figure being reached in water taken from shallow parts where it was disturbed by steamboat traffic. Loch Katrine water as delivered at Glasgow was found (1892) to contain 74 organisms per cubic centimetre, while the Loch of Lintrathen at the foot of the Grampians, from which Dundee is supplied, gave from 94 to 260, or an average of 170, the samples having been taken from the service pipe inside the city. This water at its exit from the lake only contained 30 per cubic centimetre, while near the shore the average number of organisms was 4000 per cubic centimetre. Frankland remarks that lake water contains a very small number of micro-organisms, as one would expect considering the opportunities afforded for prolonged subsidence. Lake water consequently contains a much smaller proportion of organisms than that of the streams running into them—a fact which is strikingly exemplified in the case of Loch Lintrathen just referred to and the two principal rivers that discharge into it. The streams contained 1700 and 780 organisms per cubic centimetre respectively, whereas the water delivered at Dundee only contained 30. Stephenson and Tidy[4] observe that "water stored in large lakes is as a rule potable, soft, and little liable to serious pollution from animal matters, but with very small lakes and ponds the water is often more largely contaminated, since the proportion of sewage and drainage from manured lands is great in proportion to the volume of the affluent water."

GENERAL CONCLUSIONS.

The general conclusions to be drawn from the results of means of obtaining it, but this was not so in the commune under consideration, and the local authority (*conseil municipal*) had exceeded its powers in proposing to assign an annual salary to a medical man who would attend all the inhabitants, rich and poor indiscriminately, without taking fees from individual patients.

Responsibilities of Pharmaceutical Chemists and Parents.

In December, 1906, a girl, 12 years of age, asked a pharmaceutical chemist for something which would destroy warts growing on her hands. He gave her some nitrate of mercury, telling her that she must apply it to the warts with the end of a match every two hours. After the first application her hands and arms were swollen and her hands were severely burned; three months subsequently cicatrices had formed and recovery was still incomplete. The girl's mother brought an action against the pharmaceutical chemist for 10,000 francs, on the ground that her daughter had suffered material injury on account of the scars; moreover, she had been practising on the piano with a view to becoming a teacher of music, but her injuries had prevented her from playing for several months. The court ordered the defendant to pay 50 francs fine and 500 francs damages, as although the application of the mercurial caustic had not affected the girl's health she had nevertheless sustained a definite injury because the cicatrices would probably not disappear entirely; the mother was also to blame for having failed to carry out the directions of the pharmaceutical chemist and for having intrusted her child to a servant, whereas if she had been more careful the accident might have been avoided.

Typhoid Fever in Algeria.

There have recently been many cases of typhoid fever at Blidah, and in consequence the general in command of the 19th Army Corps has been inspecting the barracks of the 1st regiment of the Chasseurs d'Afrique. These have been evacuated and all necessary sanitary measures have been taken. 18 patients were moved into hospital and of these six have died.

A Hospital Ward for the Victims of Motor-cars.

About a year ago a New York barrister was the victim of a motor-car accident just outside Lisieux. He was taken to the hospital of that town and died there some weeks later. In honour of his memory the family of the deceased have founded a new ward which is to be specially used for the victims of motor-car accidents and the foundation stone was recently laid in the presence of representatives of the family, while the Mayor of Lisieux made a speech thanking those who had so generously added to the resources of the hospital.

Sept. 17th.

COPENHAGEN.

(FROM OUR OWN CORRESPONDENT.)

The Danish General Medical Association.

ON August 22nd and 23rd the twenty-ninth meeting of the Danish General Medical Association was held in Copenhagen, and at the same time the association celebrated the fiftieth anniversary of its origin. It was founded on Sept. 1st, 1857, by 80 country practitioners and its members have gone on steadily increasing until at the beginning of the meeting just finished they numbered 1300; in other words, they included nearly all the practitioners of Denmark. One of the great events of the meeting was that the Association of Junior Medical Men, the membership of which comprises all Danish medical men not yet in practice, became incorporated with the older association, so that now practically all the medical men of Denmark to the number of 1600 are united in one strong society. The activity of the Danish General Medical Association has, during its long existence, been very advantageous both to the public at large and to the profession itself. Here I will only mention one of the many difficult questions which the association has brought to a successful issue. At the first meeting in 1857 Dr. Krebs read a paper on the distress prevalent among the manufacturing population, for the alleviation of which he recommended the foundation of sick clubs. As a philanthropic institution the sick clubs were so strenuously supported by the practitioners, that an astonishing development has taken place, with the final result that perhaps one-half of the population of Denmark belongs to such clubs or friendly societies. In 1892 a law was passed concerning the recognition and support by the State of such sick clubs as comply with certain conditions. At the present time 379 clubs, with a membership of 500,000 persons, are recognised by the State, and the sum paid in support of them by the State runs into millions of crowns. Against this overwhelming coalition of clubs the practitioners were often unable to hold their own, but the Danish General Medical Association has finally succeeded in creating a *modus vivendi* to the satisfaction of both parties concerned, so that now the machinery works quite smoothly. It is to be hoped that, backed up as it is now by the whole of the profession, the Danish General Medical Association will be able to assist in working out a bright future for its members.

Treatment of Lupus.

Among the scientific contributions to the meeting the report of the director of the Finsen Light Institute, Dr. Forchhammer, took a prominent place. Having chosen the different local treatments of lupus for his subject, he conceded that the x rays were certainly able to do a considerable amount of good, especially in the hypertrophic form of lupus, but recurrence took place only too easily. In some cases recovery might be brought about by freezing the affected area but necrosis was not seldom seen to set in, especially in the case of the tip or alæ of the nose being treated in this way, so that the patient's last state was worse than his first. The best form of local treatment was the Finsen light treatment. In cases of more than five years' standing it was often impossible to get a successful result, but even in these cases the patients were as a rule considerably improved and the spreading of the destructive process was prevented. In more recent cases the results were extremely satisfactory and such cases might in the future be expected to form the majority of the clinical material of the institute. Out of 500 recent cases whose duration was from one to four years 53 per cent. had recovered, and this result had been verified by observation extending over two years or more. An additional proportion of 22 per cent. had also recovered, but the time of observation was too short to decide whether the good effect would be permanent; 12 per cent. were still under treatment on account of frequent relapses usually arising in the mucous membrane of the nose. In several of these cases the prognosis was, perhaps, bad. In 13 per cent. the treatment had been discontinued and of these patients about one-half had died. Dr. Forchhammer illustrated his remarks by showing about 100 lupus patients who had not previously made their appearance at any congress.

The National Serum Institute of Denmark.

At the same meeting Dr. Thorvald Madsen read a paper on the work of the National Serum Institute of Denmark. This institution provides the profession with all the needed antidiphtheria serum at a nominal price. Researches carried out by Dr. Madsen and Dr. Henderson having shown that two or three days were required before the maximum amount of diphtheria antitoxin passed into the blood from a quantity injected into the subcutaneous tissue, Dr. Madsen recommended intravenous injections in exceptionally serious cases. It would also be well to give preventive injections where a spreading of the infection was likely to occur—as, for instance, in schools. By this means Dr. Maag had been able to stamp out an epidemic in a Danish public school. Professor Dreyer's researches on the standardisation of the Widal test were then alluded to. When carried out in the usual way with living typhoid bacilli the test was very inaccurate, as the same serum might agglutinate one race of bacilli and fail to do so with another. Professor Dreyer had therefore prepared a standardised emulsion of typhoid bacilli killed by means of formol and this emulsion was more sensitive than the living bacilli, at the same time giving absolutely constant results. Killed standardised emulsions of typhoid and paratyphoid bacilli are supplied to the profession by the institute. Dr. Madsen showed a handy and inexpensive thermostat devised by Professor Dreyer. It could be purchased for 5*s*. and enabled any practitioner to carry out for himself the Widal macroscopic test.

Sept. 16th.

ENTERIC FEVER IN THE PONTYPOOL DISTRICT.—The report of Dr. R. W. Johnstone, of the Local Government Board, who investigated the recent outbreak of enteric fever in the Pontypool district, has just been issued. Dr. Johnstone states that there can be little doubt that enteric fever was started at Pontypool b water from the well of the gasworks.

1903—before Dr. Nash got his own way with regard to shell-fish—there were 20 cases of typhoid fever for every 10 000 of the population; during the four years 1903 to 1907 there have been only 3 cases per 10,000; and from Jan. 1st last to August 31st there were only two cases. What does this mean? It means that not only have we a reputation second to no other seaside town but also that a large expenditure has been saved in connexion with this disease alone. The expenditure in connexion with each typhoid patient is not less than £10. and if you compare the 20 per 10,000 with the 3 you will find that the expenditure must have been lessened by £700. All this I cannot claim is due to Dr. Nash, but it is proof that you have a man of great ability who is doing his level best for the town whether it gives offence to individuals or not. I say, when you have an officer who is doing good service he should be appreciated. If you have an officer who you think it is desirable should be removed or that some-one else should take his place—if you like to put it that way—the man is entitled to fair notice; and I say that no public body should be guilty of kicking a man out without giving him fair notice or sufficient and good reason for getting rid of him. At the last monthly meeting I stated that some members voted without considering what the result might be. We all make mistakes. I have made many, and I admit it frankly, but when I have made a mistake no one can say I have not admitted it and apologised. Men may change their minds without lessening their dignity, and I feel sure if certain members will do that to-day they will never regret it and they will have the satisfaction of knowing that although they were parties to doing something which according to the views of the great majority was not right they did the next best thing—retraced their steps and did their best to put things right.

Alderman Francis added that at the last meeting Councillor Garon, although he had nothing against Dr. Nash, objected to a man being appointed for a term without the council having an equal right. He agreed with Councillor Garon that all the chief officers should be appointed on equal terms and would amend the committee's recommendations accordingly. He proposed that the resolution to advertise for a medical officer be rescinded and he said that if that were carried he would move that Dr. Nash be reappointed at £600 a year but that the appointment could be determined by three months' notice on either side.

Councillor COLIN CAMPBELL, chairman of the Education Committee, for which Dr. Nash is also medical officer, seconded the motion.

Councillor LEANEY opposed on the ground that Dr. Nash had not been loyal to the borough. He alleged that Dr. Nash had given evidence detrimental to the town before the House of Lords and had also said that he would not bathe in the sea off Southend for £1000.

Questioned by Alderman FRANCIS Councillor LEANEY admitted that there was no official record of Dr. Nash having made the remark about the £1000. It was stated, Councillor Leaney said, when Dr. Nash was on the pleasure steamer the *Koh-i-Noor*.

Alderman FRANCIS: The impression you gave was that the remark was in the blue-book now in your hand.

Councillor HUBBARD considered that it was very undignified on Councillor Leaney's part to introduce a remark made casually on a pleasure trip, as even if it had been made it might have meant nothing. As for Dr. Nash's evidence before the House of Lords, if it were true no one had cause to complain. He hoped the day would never come when Southend had a medical officer who would be prepared to go into a witness-box and say that which was not true to please any member of the council.

After a heated debate the Health Committee's recommendation was defeated by 12 to 11 votes.

Councillor LEANEY suggested that to effect a compromise a private meeting of the council should be called; but Alderman FRANCIS said that he should be opposed to anything private. Many things had been said, and it would be hinted that many more might be said. Whatever more there was to say it should be said publicly.

CARDIFF INFIRMARY.—At a meeting of the committee of the Cardiff Infirmary held on Sept. 12th it was reported that £17,746 had been received towards the erection of the new wing for the institution, leaving £12,252 still to be obtained.

THE STUDY OF TROPICAL MEDICINE: THE MARY KINGSLEY MEDAL.

WHEN Miss Mary Kingsley, the famous African traveller, died in 1900, the Liverpool School of Tropical Medicine decided to commemorate her work in the tropics by the issue of a "Mary Kingsley Medal," to be presented to those who have distinguished themselves in the work of special research into tropical medicine. The medal was designed by Mr. J. H. McNair and Professor Allen of the University of Liverpool. It is in bronze and contains a bas-relief portrait of Miss Kingsley on the obverse and a suitable design on the reverse with the inscription "Devotion to Science." The first four recipients were presented with the medals by H R H. Princess Christian, honorary president of the school. The later presentations have since been made, by the courtesy of His Majesty's Secretary of State for Foreign Affairs, through the British Ambassadors to the various countries concerned.

The following is the official list supplied to us of those who have received the medal, with a note of their work:—

"1. Colonel David Bruce, F.R.S., C.B., R.A.M.C. He discovered the cause of Malta fever, an important disease of warm climates, in 1887. In 1894 he showed that the famous nagana, or tsetse-fly disease of cattle in Africa, is caused by parasites belonging to the group called trypanosomes, which are carried from one animal to another by the agency of glossina or tsetse flies. In 1903 he was the head of the Commission which clearly demonstrated that another kind of trypanosome is the cause of sleeping sickness in man and is carried by another kind of glossina. Since then he has ably directed an extensive inquiry into Malta fever which has proved that that malady is produced by the milk of infected goats.

2. Geheimrath Professor Dr. Robert Koch, Nobel Laureate. He ascertained the cause of cholera in 1883, shortly after his epoch-marking discovery of the cause of tuberculosis. Later he paid many visits to the tropics to study tropical diseases and has added much to our knowledge regarding them, especially his discovery of the frequency of malarial infection in children.

3. Dr. A. Laveran, of the Pasteur Institute, Paris, and D.Sc., University of Liverpool. In 1880 he made the great discovery that malarial fever is caused by parasites in the blood and has added much to our knowledge of this disease and also of other tropical diseases, especially those caused by trypanosomes in man and animals.

4. Sir Patrick Manson, F.R.S., K.C.M.G., of the London School of Tropical Medicine. In 1878 he discovered that one of the parasites of man belonging to the group of filaria is carried by a kind of mosquito and since then he has contributed much to our knowledge of these parasites and the diseases caused by them and also to tropical medicine in general.

5. Dr. Basile Danilewsky, professor of physiology, University of Kharkoff. He discovered numerous parasites of the blood in a large number of animals shortly after Laveran's discovery was made, thus throwing much light on diseases of man due to similar organisms. His observations have been the basis of much of the work done since then on the subject.

6 Dr. Charles Finlay, chief sanitary officer of Cuba. In 1880 he originated the theory that yellow fever is carried by mosquitoes. By careful observations he ascertained the species of mosquito concerned and thus enabled the American Commission under Major Reed to verify the theory finally in 1901. The methods of preventing the disease, used since then with such brilliant success in Havana and Panama, were largely based upon his original suggestion.

7. Dr. Camille Golgi, professor of pathology, University of Pavia. In 1887 he made a complete study of the life-cycle of the parasites of malaria, showed that they belong to different varieties, and demonstrated that the attack of fever is caused by their sporulation, thus elucidating the whole subject of the infection within the human body.

8. Colonel W. C. Gorgas, United States Army. As chief sanitary officer of Havana he gave practical effect in 1902 to the discoveries of Finlay and of the American Commission in connexion with yellow fever and by his energy and capacity succeeded in banishing the disease from the city. Since then, as chief sanitary officer of the Canal Zone of the Isthmus of Panama, he has kept that area practically free

disabled or dies whilst on duty his family is entitled to the full pension without reference to the period for which he has been in the service. In return for these emoluments the country practitioners must undertake free public vaccination of the poor (this was the main point of controversy), free treatment of the poor of the parish, and certain services in the infirmaries. The cost of the pensions will be borne partly by the practitioners themselves, a deduction of 3 per cent. being made from their salaries, but the chief burden will be borne by the State which will have to pay about £5000 yearly under this heading. The new statute will come into force on Jan. 1st, 1908. The benefits conferred by it are insignificant considering the amount of hard work done by the country practitioners, but a beginning has now been made and further improvements in the position of these medical men are only a question of time.

Poisoning by Solutions of Caustic Potash.

Dr. von Pirquet and previously Dr. Teleky have investigated the conditions attending fatalities due to the domestic use of solutions of caustic potash for cleansing purposes and the results of their investigations were discussed at a recent meeting of the Vienna Society of Practitioners. The poison could be obtained easily by children, as no legal restriction was put on its sale. The strength of the solutions in question varied from 7·75 per cent. to over 30 per cent. and the accidents were mostly due to the reprehensible custom of allowing children to drink from bottles. Sometimes the poison was contained in ordinary beer or wine bottles, so that a mistake was easily made, especially by children, who form the majority (80 per cent) of the victims. In seven years these investigators collected particulars of 362 cases from the Vienna hospitals, with a direct mortality of 18·5 per cent.; 10 per cent. of the patients had to be operated upon. Of those who survived the injury or the operation, 93 per cent. suffered from stricture of the œsophagus, with fatal complications in 5 per cent. at a later stage. Treatment by thiosinamin proved beneficial in Dr. Teleky's hands, apart from surgical measures. In the discussion there was a general agreement to the effect that the unrestricted sale of the poison should be prevented and that registered druggists only should be permitted to sell caustic soda or caustic potash, in definite low concentrations, and only in vessels of a special pattern. The addition of a substance having a disagreeable odour as an indication of danger was also thought to be worth consideration.

Partial Removal of a Tumour of the Hypophysis Cerebri.

In THE LANCET of June 1st, p. 1528 mention was made of a new operation by Professor Schloffer of Innsbruck, on a case of tumour of the hypophysis cerebri. The patient, who had been suffering from constant headache and drowsiness, improved to some extent after the operation, his pains disappeared, and his general condition was good. Death occurred ten weeks after the operation and eight days before the closing scene headache and giddiness reappeared for a short time. A similar attack occurred the next day, then a third five days later, and the fourth proved fatal. The terminal attack was accompanied by vomiting, bradycardia, and Cheyne-Stokes breathing. Respiration ceased first and the heart's action subsequently. The post-mortem examination showed that the size of the growth had been underestimated, as more than four times the quantity removed at the operation had been left in the brain. The tumour penetrated into the left lateral ventricle; it had caused chronic hydrocephalus, it had destroyed parts of the optic nerves and the corpus callosum, and the concomitant hypoplasia of the genital organs was perhaps also due to its presence. The wound on the base of the skull had healed perfectly with a solid scar of connective tissue, which proved that in special cases the transnasal method of access to the hypophysis is permissible. The operation, which resulted in improvement of the distressing condition of the patient, had undoubtedly been of benefit by the diminution of compression which followed removal of a fifth of the tumour and the escape of fluid. Death occurred when the growth of the tumour finally closed the foramen of Monro, thus causing an acute obstruction in the lateral ventricle. The principal lesson taught by this case is the possibility of operating through the nose on the base of the brain without producing meningitis.

Sept. 14th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Loch has been recognised as *privat docent* of Experimental Pathology.—*Berlin:* Dr. Peter Bergell, Assistant in the First Medical Clinic, Dr. Victor Schmieden, Assistant in the Ziegelstrasse Surgical Clinic, and Dr. Heinrich Poll, Assistant in the Institute of Anatomy and Biology, have been granted the rank of Titular Professor.—*Bologna:* Dr. Arturo Lanzerini has been recognised as *privat docent* of Internal Pathology and Dr. Alfredo Filè Bonarrola as *privat-docent* of Children's Diseases.—*Bonn:* The title of Professor has been granted to Dr. Max zur Nedden, *privat-docent* of Ophthalmology, and to Dr. Rudolf Eschweiler, *privat-docent* of Otology.—*Budapest:* Dr. Ladislaus Rohrer has been recognised as *privat docent* of Medical and Physical Chemistry.—*Cincinnati (Miami Medical College):* Dr. William D. Porter has been appointed Professor of Midwifery.—*Göttingen:* The title of Professor has been granted to Dr. Alfred Schittenhelm, *privat-docent* of Medicine, and to Dr. Rudolf Staehelin, of the University Clinic.—*Greifswald:* Dr. Guido Fischer has been recognised as *privat-docent* of Odontology.—*Kharkoff:* Dr. S. Pêtin has been recognised as *privat-docent* of Histology.—*Königsberg:* Dr. Isfried Hofbaur has been recognised as *privat docent* of Midwifery and Gynæcology; Dr. Arthur Brückner of Würzburg has been recognised as *privat docent* of Ophthalmology; Dr. Kurt Goldstein as *privat-docent* of Mental Diseases; and Dr. Ernst Laqueur of Halle as *privat-docent* of Physiology.—*Kiel:* Dr. Leopold Heine of Greifswald has been appointed Professor of Ophthalmology.—*Montreal (McGill University):* Dr. J. L. Todd has been appointed Professor of Parasitology and Dr. Andrew McPhail Professor of the History of Medicine.—*Naples:* Dr. Vittorio Scaffidi has been recognised as *privat-docent* of General Pathology; Dr Giovanni Di Cristini as *privat-docent* of Internal Pathology; Dr. Eugenio La Pegna as *privat-docent* of Neurology and Psychiatry; Dr. Ernesto Sgrosso as *privat docent* of Ophthalmology; and Dr. Giuseppe Cristali as *privat-docent* of Midwifery and Gynæcology.—*New York (College of Physicians and Surgeons):* Dr. William K. Draper, Dr. George B. Lockwood, and Dr. Van Horne Norrie have been appointed Assistant Professors of Medicine; Dr. Royal Whitman, Assistant Professor of Orthopædics; and Dr. James D. Voorhees, Assistant Professor of Midwifery.—*Padua:* Dr. Luigi Messedaglia has been recognised as *privat docent* of Internal Pathology.—*Pavia:* Dr. Ettore Fornaroli has been recognised as *privat docent* of Medical Pathology and Dr. Gino Acconci and Dr. Carlo Pinto as *privat-docenten* of Midwifery and Gynæcology.—*Pisa:* Dr. Alberto Marrassini has been recognised as *privat-docent* of General Pathology; Dr. O. Torri as *privat-docent* of Internal Pathology; and Dr. Guido Ferrarini as *privat-docent* of External Pathology.—*Prague (Bohemian University):* Dr. Johann Jansky has been recognised as *privat-docent* of Mental Diseases.—*Rome:* Dr. Giulio Galli has been recognised as *privat-docent* of Internal Pathology and Dr. Enrico Fossatoro as *privat-docent* of Traumatic Diseases.—*Rostock:* Dr. Reinmöller has been appointed Lecturer in Odontology.—*Tübingen:* Dr. Sellheim has been appointed Professor of Gynæcology in succession to Dr. Döderlein.—*Turin:* Dr. Carlo Foà has been recognised as *privat-docent* of Experimental Physiology; Dr. Girolamo Piccardi as *privat-docent* of Dermatology; Dr. Luigi Bobbio as *privat-docent* of External Pathology; Dr. Stefano Santucci as *privat-docent* of Ophthalmology; Dr. Santi Pusateri as *privat-docent* of Otology and Laryngology; Dr. Camillo Palazzo as *privat-docent* of Odontology; Dr Stefano Balp as *privat docent* of Demography and Medical Statistics; and Dr. Edoardo Audenino and Dr. Francesco Barzio as *privat-docenten* of Psychiatry.—*Utrecht:* Dr. F. H. Quix has been appointed Lecturer in Otology and Laryngology.—*Vienna:* Dr. Josef Meller has been recognised as *privat-docent* of Ophthalmology.

THE PLAGUE IN INDIA.—The prize for the best essay on the best methods of prophylaxis against plague, which was offered last April by our contemporary the *Indian Medical Gazette*, has been awarded to first class hospital assistant P. S. Ramachandrier, of the Mysore Medical Service, who until lately was a member of the Plague Research Commission, and is well known as the editor, Anant Santram Malve, of the in conjunction w five other of the 76 towns; the annual death-rates from these diseases, however, ranged upwards to 3·0 in Great Yarmouth, 3·1 in Bootle, 3·3 in Rotherham and in Gateshead, 3·4 in Liverpool, 3·5 in Sheffield, 3 6 in West Ham, and 3·9 in Cardiff. The fatal cases of diarrhœa have steadily increased in successive weeks from 39 in the second week of the quarter to 278 in the week under notice; the annual death-rates last week from this disease ranged upwards to 2·0 in Hull, 2·2 in Walsall, 2·5 in Sheffield, 2·6 in Liverpool, 2·7 in West Ham, 3·1 in Bootle, and 3·3 in Rotherham. The deaths from whooping-cough, which had been 76 and 80 in the two previous weeks, further rose last week to 95, the highest death-rates from this cause being 1·4 in West Hartlepool and in Merthyr Tydfil, 1·7 in Gateshead, and 2·0 in Great Yarmouth. The 39 fatal cases of diphtheria corresponded with the number in the preceding week, and included 11 in London, four in West Ham, and three each in Manchester and in Salford. The deaths from measles, which had been 84, 73, and 71 in the three preceding weeks, further declined in the week under notice to 35, of which 10 occurred in London and 10 in Cardiff, the annual rate in the latter town from this disease being 2·8 per 1000. The mortality from both scarlet fever and enteric fever showed a considerable reduction from that in other recent weeks and was not excessive in any of the large towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had increased from 2658 to 3816 in the 18 preceding weeks, had further risen to 3871 at the end of last week; 574 new cases were admitted during the week, against 440, 557, and 657 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory system, which had been 129 and 116 in the two previous weeks, rose again to 122 in the week under notice, but were five below the corrected average number in the corresponding period of the five years 1902-06. The causes of 34, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Manchester, Bristol, West Ham, Newcastle-on-Tyne, Hull, Salford, Portsmouth, and 51 other of the 76 towns; there were nine uncertified deaths in Liverpool, four in Birmingham, and three each in Sheffield, Bradford, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 13·7 and 13 6 per 1000 in the two previous weeks, increased to 15·3 per 1000 in the week ending Sept. 14th, and was 3·0 per 1000 in excess of the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·5 in Perth and 14 6 in Edinburgh, in Aberdeen, and in Greenock, to 15·7 in Glasgow and 16 7 in Dundee. The 532 deaths in these towns showed an increase of 61 over the number in the previous week, and included 69 which were referred to the principal epidemic diseases, against 65, 62, and 58 in the three preceding weeks. These 69 deaths were equal to an annual rate of 2·0 per 1000, which was 0·4 per 1000 above the mean rate last week from the principal epidemic diseases in the 76 large English towns; they included 22 which were referred to "fever," 20 to diarrhœa, 18 to whooping-cough, six to diphtheria, and three to measles, but not any to small-pox or to scarlet fever. The deaths from "fever," which had been seven, 19, and 11 in the three preceding weeks, rose again to 22 in the week under notice, and included 11 in Glasgow, eight in Edinburgh, and two in Dundee; of these 22 deaths 10 in Glasgow, six in Edinburgh, and two in Dundee resulted from cerebro-spinal meningitis. The fatal cases of diarrhœa, which had been 15 and 22 in the two previous weeks, declined again to 20 last week, and included 13 in Glasgow, three in Aberdeen, and two in Dundee. The deaths from whooping-cough, which had been 22, 19, and 22 in the three preceding weeks, decreased in the week under notice to 18, of which eight occurred in Glasgow, six in Edinburgh, and two in Leith. The fatal cases of diphtheria, which had been eight, seven, and one in the three preceding weeks, rose again to six last week, and included five in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 51 and 57 in the two preceding weeks, further rose to 61 in the week under notice, and slightly exceeded the number in the corresponding period of last year. The causes of 20, or 3·8 per cent., of the deaths in these eight towns last week were not certified or not stated: in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 18·6 and 20·7 per 1000 in the two preceding weeks, declined again to 17·6 per 1000 in the week ending Sept. 14th. During the first 11 weeks of the current quarter the death-rate has averaged 18·7 per 1000, the rate during the same period being 11·9 in London and 12·5 in Edinburgh. The 132 deaths of Dublin residents registered during the week under notice showed a decline of 23 from the number in the preceding week, and included 15 which were referred to the principal epidemic diseases, against 17 and 12 in the two previous weeks; of these, nine resulted from diarrhœa, two from diphtheria, two from "fever," one from measles, and one from whooping-cough, but not any from small-pox or from scarlet fever. These 15 deaths were equal to an annual rate of 2 0 per 1000, the death-rate for the same week from the principal epidemic diseases being 1·4 in London and 2·4 in Edinburgh. The fatal cases of diarrhœa, which had been four, eight, and five in the three preceding weeks, rose again last week to nine. The 132 deaths from all causes during the week included 28 of children under one year of age and 35 of persons aged upwards of 60 years: the deaths of infants were slightly below the number in the previous week, while those of elderly persons showed a very marked decline. One death from violence and three inquest cases were registered during the week; and 62, or 47 per cent., of the deaths occurred in public institutions. The causes of two, or 1·5 per cent., of the deaths registered in Dublin last week were not certified; in London all the causes of death were duly certified, while in Edinburgh the proportion of uncertified deaths was 2·1 per cent. The 125 deaths in Belfast included five which were attributed to cerebro-spinal fever.

VITAL STATISTICS OF LONDON DURING AUGUST, 1907.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·2 per 1000 of the population, estimated at 4,758,218 persons in the middle of the year; in the three preceding months the rates were 7·1, 7·2, and 8·7 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, Hammersmith, the City of Westminster, Hampstead, and Lewisham; and the highest rates in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. One case of small-pox was notified last month in Poplar and remained under treatment in the Metropolitan Asylums Hospital at the end of the month. The prevalence of scarlet fever showed a slight decline from the excessive amount in the preceding month; this disease was proportionally most prevalent in Shoreditch, Bethnal Green, Stepney, Poplar, Bermondsey, and Woolwich. The Metropolitan Asylums hospitals contained 3709 scarlet fever patients at the end of last month, against 2777, 2975, and 3578 at the end of the three preceding months; the weekly admissions averaged 469, against 368, 390, and 500 in the three preceding months. Diphtheria also showed a slightly diminished prevalence as compared with that recorded in July; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Fulham, Chelsea, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. There were 834 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 933, 806, and 913 at the end of the three preceding months; the weekly admissions averaged 116, against 121, 107, and 140 in the three preceding months. Enteric fever was more prevalent in August than in any other month since April last; this disease was proportionally most prevalent in Fulham, Hackney, the City of London, Battersea, Wandsworth, and Deptford. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 47, 57, and 50 at the end of the three preceding months, had risen again to 65 at the end of last month; the weekly

Dr. Arthur C. Latham, members of the consulting and active medical staff of St. George's Hospital; Dr. S. S. Sprigge, representing THE LANCET; Dr. C. Spencer Cobbold, Mr. Charles E. Underhill, Dr. A. J. Jex-Blake, Mr. G. E. Friend, Mr. Arthur Johnson, and Dr. R. S. Trevor. The first part of the service was held in the old parish church and both there and at the graveside the officiating clergyman was the Rev. F. W. Pakenham Gilbert.

LITERARY INTELLIGENCE.—Mr. H. J. Glaisher of Wigmore-steeet is publishing for the Ambrose Company "Anthropometrical Schedules" prepared by Mr. John Gray, B.Sc., Secretary to the Anthropometrical Committee of the British Association, and also a "Book of Instructions for Taking Anthropometrical Measurements" by the same author.

DONATIONS AND BEQUESTS.—Mr. William Richardson of Kingston-upon-Hull has bequeathed £2000 to the Hull Royal Infirmary, £1500 to the Hull and Sculcoats Dispensary, and £1000 to the Victoria Hospital for Poor Sick Children, Kingston-upon-Hull.—The Infants' Hospital, Vincent-square, Westminster, has received through the ladies' committee a donation of £500 from Mrs. Heron-Allen for the endowment of a cot.—Mr. Henry Finlay has given by will, among other bequests, £500 each to the Poplar Hospital; the Home for Incurables, Putney; the British Home for Incurables, Streatham; the Fever Hospital, Liverpool-road, N.; the Royal Sea Bathing Infirmary, Margate; the North London Hospital, Holloway-road; the Earlswood Asylum for Idiots; St. John's Hospital for Diseases of the Skin, Leicester-square; the National Orthopædic Hospital, Great Portland-street; the Hospital for Diseases of the Throat, Golden-square; the National Hospital for the Paralysed and Epileptic, Bloomsbury; the Asylum for Deaf and Dumb Children, Old Kent-road and Margate; the Hospital for Sick Children, Great Ormond-street; the Cancer Hospital, Brompton; the London Hospital; Guy's Hospital; St. Thomas's Hospital; and the Consumption Hospital, Victoria Park, E.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

DAVIDSON, GEORGE EDWARD, M.B., B.C. Cantab., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Shere District of the county of Surrey.

DERRY, BARTHOLOMEW GIDLEY, L.R.C.P. Lond., M.R.C.S., has been re-apppointed Medical Officer of Health for Bodmin Urban District.

DE SYLVA, E. M. J., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Scalloway District of the county of Shetland.

FOLEY, CORNELIUS, L.R.C.P. & S., L.M. Irel., has been appointed District Medical Officer by the Ross (Herefordshire) Board of Guardians.

GRANDAGE, WILLIAM B., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Resident Medical Officer to Queen Charlotte's Lying-in Hospital

HARVEY, FRANK, M.R.C.S., L.S.A., has been appointed District Medical Officer by the St. Columb Major (Cornwall) Board of Guardians.

HENDERSON, G., M.D. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Coldstream District of the county of Berwick.

IMRIE, G. J., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Levenwick District *of the county of* Shetland.

LAVERS, NORMAN, M.D. Brux., M.R.C.S., L.R.C.P. Lond., has been appointed Physician Superintendent of Bailbrook House, Bath.

RICHARDS, JOHN *BARROW OSBORNE, L.R.C.P. & S. Edin.*, L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Wadebridge (Cornwall) Urban District.

SHARP, P. J., M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ollaberry District of the county of *Shetland*.

SINGER, H. DOUGLAS, M.D. Lond., M.R.C.P. Lond., has been appointed Director of the Psychopathic Institute of the State of Illinois in *the Eastern Hospital for the Insane, Illinois, U.S.A.*

SKINNER, D., L.R.C.P. & S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Lauder *District* of the county of Berwick.

STEWART, G. N., M.B., M.S. Edin., D.P.H. Cantab., Professor of Physiology in the *University of Chicago, has been appointed* Director of the Laboratory of Experimental Medicine, Western Reserve University, Cleveland, U.S.A.

TEMPLETON, *WILLIAM, M.B., Ch.B. Glasg.*, has been appointed Extra Anæsthetist to the Glasgow Samaritan Hospital for Women.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 and fees.

BIRMINGHAM GENERAL HOSPITAL.—Two Receiving-room Officers. Salary £150 per annum.

BRENTFORD UNION WORKHOUSE AND SCHOOLS, Isleworth, W.—Second Assistant Medical Officer, unmarried. Salary £125 per annum, with lunch and tea.

BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road.—House Surgeon. Salary at rate of £80 a year, with *board, lodging*, and washing.

BUXTON, DERBYSHIRE DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CAMBERWELL HOUSE ASYLUM, S.E.—Second Assistant Medical Officer. Salary £150 *per annum, rising to* £200, with board, apartments, and laundry.

CENTRAL LONDON *OPHTHALMIC HOSPITAL*, Gray's Inn-road, *W.C.*—House Surgeon. Salary at rate of £50 per annum, with board and residence.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Pathologist. Salary 100 guineas per annum. Also Two House Physicians for six months. Salary at rate of £50 per annum, with board, washing, and residence.

CROYDON GENERAL HOSPITAL.—Senior and Junior House Surgeons. Salary of former £105, and of latter £60, with board, *laundry*, and residence in each case.

DORCHESTER, DORSET COUNTY HOSPITAL.—House Surgeon, unmarried. Salary £100, with board and lodging

DURHAM COUNTY HOSPITAL.—House Surgeon. Salary £120, with board and lodging.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark *Bridge-road*, S.E. —Clinical Assistants

FARRINGDON GENERAL DISPENSARY, 17, Bartlett's Buildings, Holborn Circus, E.C.—Resident Medical Officer. Salary £120 per annum, with apartments, coal, gas, and attendance. Also Honorary Dental Surgeon.

FIFE DISTRICT ASYLUM, Cupar-Fife.—Junior Assistant Medical Officer. Salary £120, with rooms, board, and attendance.

GLOUCESTER, GENERAL INFIRMARY AND THE GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeoncy for six months. Salary at rate of £30 per annum, with board, residence, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. —Resident House Physicians for six months. Honorarium £25.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, Assistant Casualty Medical Officer, and House Physician, unmarried, all for six months. Salary £20, with board and residence in the hospital in each case.

admissions averaged 15, against nine, 13, and nine in the three preceding months. Erysipelas was proportionally most prevalent in Finsbury, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Woolwich. The 25 cases of puerperal fever notified during the month included five in Southwark, five in Lambeth, three in Stepney, and two each in Fulham, Hackney, Bermondsey, and Wandsworth. Of the 13 cases of cerebro-spinal meningitis notified during the month, two belonged to Shoreditch, two to Bethnal Green, two to Stepney, two to Camberwell, and one each to Chelsea, Bermondsey, Lambeth, Battersea, and Lewisham.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending August 31st the deaths of 4102 persons belonging to London were registered, equal to an annual rate of 11·2 per 1000; in the three preceding weeks the rates had been 14·0, 12·2, and 11·4 per 1000. The death-rates last month ranged from 5·7 in Hampstead, 8·0 in Stoke Newington, 8·6 in the City of Westminster, 8·8 in Lewisham, 9·0 in Hackney, and 9·2 in Hammersmith, to 13·2 in Holborn and in Bethnal Green, 13·3 in Stepney, 13·5 in Finsbury, 14·0 in Southwark and in Bermondsey, and 16 9 in Shoreditch. The 4102 deaths from all causes included 493 which were referred to the principal infectious diseases; of these, 130 resulted from measles, 45 from scarlet fever, 50 from diphtheria, 104 from whooping-cough, 15 from enteric fever, one from ill-defined pyrexia, and 148 from diarrhœa. No death from any of the principal infectious diseases was recorded last month in Hampstead; they caused the lowest death-rates in Hammersmith, the City of Westminster, Stoke Newington, the City of London, and Lewisham; and the highest rates in Fulham, Shoreditch, Stepney, Southwark, Battersea, and Greenwich. The 130 fatal cases of measles were 32 in excess of the corrected average number for the corresponding period of the five preceding years; this disease was proportionally most fatal in Fulham, Chelsea, Finsbury, Southwark, and Battersea. The 45 deaths from scarlet fever exceeded by six the corrected average number; the greatest proportional mortality from this disease was recorded in Finsbury, Stepney, Poplar, Deptford, and Greenwich. The 50 fatal cases of diphtheria was equal to the average for the corresponding period of the five years 1902–6; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, St. Marylebone, St. Pancras, Stepney, Poplar, and Deptford. The 104 deaths from whooping-cough were 18 above the corrected average number; the highest death-rates from this disease were recorded in St. Marylebone, Shoreditch, Poplar, Battersea, Wandsworth, and Greenwich. The 16 deaths from "fever" were 13 fewer than the average; they included three in Hackney and two each in St. Pancras, Battersea, and Wandsworth. The fatal cases of diarrhœa numbered only 148, against an average of 1330 in the corresponding period of the five preceding years; the greatest proportional mortality from this disease occurred in Fulham, Shoreditch, Stepney, Southwark, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was less than one third of the corrected average. There were four deaths of London residents attributed to cerebro-spinal fever last month; these deaths belonged respectively to Hammersmith, Chelsea, Shoreditch, and Bermondsey.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 98 per 1000. No death at this age was recorded in the City of London either in July or August; among the metropolitan boroughs the lowest rates of infant mortality last month were recorded in the City of Westminster, St. Marylebone, Hampstead, Holborn, Finsbury, and Lewisham; and the highest rates in Kensington, Fulham, Chelsea, Shoreditch, and Poplar.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeons: J. Andrews to the *Vivid*, for Pembroke Dockyard; J. Shand to the *Vengeance*; and A. Kidd to the *Defiance*. Surgeons: R. W. G. Stewart to Plymouth Hospital and E. F. Ellis to the *Andromeda*.

ARMY MEDICAL SERVICE.

The undermentioned Colonels are placed on retired pay:—James Magill, C.B. (dated Sept 6th, 1907); and William A. May, C.B. (dated Sept. 18th, 1907).

The undermentioned Lieutenant-Colonels from the Royal Army Medical Corps to be Colonels: Douglas Wardrop, vice A. W. P. Inman, placed on half-pay (dated August 14th, 1907); George T. Goggin, vice J. Magill, C.B. (dated Sept. 6th, 1907); and John M. Jones, vice W. A. May, C.B. (dated Sept. 18th, 1907).

ROYAL ARMY MEDICAL CORPS.

Captain Harry B. Connell, from the Seconded List, to be Captain (dated August 28th, 1907). Lieutenant-Colonel G. T. Goggin, Administrative Medical Officer at Belfast, has been appointed Principal Medical Officer of the Western Command (Chester), vice Colonel H. Martin.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Samuel J. J. Kirby to be Surgeon-Major (dated August 28th, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery: 1st North Riding of Yorkshire: Surgeon-Captain S. Farmer resigns his commission (dated August 31st, 1907).

Rifle: 2nd Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Major G. Hollies to be Surgeon-Lieutenant-Colonel (dated August 1st, 1907).

THE UNITED SERVICES MEDICAL SOCIETY.

The first meeting of this society will be held at the Royal Army Medical College, Millbank, S.W., on Oct. 10th, at 8 30 P.M., when the President, Inspector-General Sir Herbert Ellis, K.C.B., Director-General of the Medical Department of the Royal Navy, will read a short paper on the objects and uses of the society. There will afterwards be a discussion and arrangements have been made to exhibit objects of interest to members.

Lord Methuen has ordered that lectures on hygiene shall be given to all soldiers of the Eastern Command during the coming winter by officers of the Royal Army Medical Corps.

Fleet-Surgeon C. W. Andrews, R N., has been selected to represent the Admiralty at the forthcoming International Congress of Hygiene and Demography at Berlin. He represented the British navy at the last Paris Medical Congress.

Correspondence.

"Audi alteram partem."

ROYAL SOCIETY OF MEDICINE.

To the Editors of THE LANCET.

SIRS,—As I have received a number of letters from those who, like your correspondent "Puzzled," have some difficulty in describing their connexion with the above society in the Medical Directory I would suggest that Fellows of the society should describe themselves as Fell.Roy.Soc.Med. If in addition they desire to mention the section or sections to which they belong they should describe themselves as Fell.Roy.Soc.Med. (Sections —— and ——), filling in the name of the section or sections. Members of sections who are not Fellows should describe themselves as Memb. —— Section Roy. Soc. Med., filling in the name of the section to which they belong. A Fellow has the right to attend the meetings of any section. He is a member (i.e., can take part in the business) of any section corresponding to his previous societies but of no other unless duly elected thereto. There are no members of the society, but each section has members who are not Fellows of the society. Such members of sections are those who having belonged to corresponding societies (or having been only elected to the particular sections) do not wish to become Fellows of the society.

I am, Sirs, yours faithfully,

ARTHUR LATHAM,

Honorary Secretary Royal Society of Medicine.

38, Portland place, W., Sept. 17th, 1907.

*** We understand that the publishers of the Medical Directory intend to put the initials F.R.S.M. after the names of Fellows of the society. The abbreviation is a serious error.—ED. L.

In Lappland one often sees no houses and no people for 12 hours or more at a time in traversing its monstrous cliffs and ravines which are exactly similar to the Herzegovina. Hence I was sometimes driven by necessity to march distances (for example, for 15 hours incessantly over volcanic rocks) which nothing on earth but sheer geographical necessity would have induced me to march. My conclusions are so simple that they can be stated in a few words. They relate to—

1. The incalculable restorative effects of liquid at a high temperature after anything over six hours of continuous marching. So great is the effect of boiling water on the efficiency of a man undergoing a forced march of ten to 14 hours that I feel certain, from my experiments, that it is more important to provide the soldier on a long march with a small apparatus for heating liquid than with food. The extent to which boiling liquid can take the place of food was never fully realised by me until I marched 14 hours on three sandwiches and plenty of hot water. Nothing but the possession of a spirit lamp saved me from serious illness, from fatigue and exposure during some of these marches, and I have no doubt many travellers could corroborate this.

2. The imperious craving for sugar in some form which these long marches produce and the enormous importance of an adequate supply of sugar in the diet of soldiers performing much bodily exertion. I have no hesitation in saying, firstly, that the importance of sugar (owing to the consumption of the sugar in the blood by bodily exercise) is most inadequately recognised in English military diet; and, secondly, that the private soldier is too often driven to satisfy the natural craving for sugar after violent exercise by drinking alcohol. Hence he believes that alcohol is natural and does him good. I further believe that it could be shown by experiment that men who were allowed a glass of milk with four lumps of sugar in it could undergo greater fatigue on that *drink* than on almost any other.

3. The vast superiority of hot oatmeal porridge at breakfast and supper over almost every other article of food in maintaining efficiency and health during prolonged marches. Abnormal exertions, such as 16 hours of climbing, throw the real value of foods into a far stronger relief than usual. The presence or the lack of that food during an ordeal of this sort at breakfast or supper has so vast an effect on one's condition that I can scarcely imagine any general who is aware of its value overlooking it as an almost complete and most portable food for a forced march of 14 hours. It is far richer in mineral salts than meat.

4. The utility of dried figs. Given a meal of hot porridge for breakfast and supper a soldier could march without discomfort or harm for a whole day or night on a handful of figs and some hot liquid, owing to the fact that they are so full of sugar and mineral salts, which are what the marching man chiefly needs. Anyone who overlooks the value of the fig in catering for the food of an army corps on campaign commits a great blunder. In a rapid campaign the great requisite in food is the *irreducible minimum* for health and strength, which is not the case in time of peace. I believe that a scientific medical investigation of the effects of the ordinary soldiers' diet and of such a diet as the one indicated above in the case of men undergoing long tests of endurance would be exceedingly valuable from a military point of view as well as of great scientific interest, and I also believe that a medical investigation of the dietetic tastes of persons who are known to perform so much bodily exertion as the leading lawn-tennis players could scarcely fail to disclose new and valuable facts on the relation of athletics to food values. The Victoria Food Museum in Bethnal Green-road lately contained a sample of convict diet. The complete absence of fat at breakfast and supper, and the complete absence of treacle or jam except in the "groats," is certainly a blunder if it be desired to obtain the greatest amount of bodily labour from the convict.

I am, Sirs, yours truly,

F. W. PAYN.

Stromnes, Ulfsfjord, Tromso, Norway, Sept. 2nd, 1907.

THE COOL SUMMER AND DIARRHŒAL DISEASES.

To the Editors of THE LANCET.

SIRS,—The interesting annotation on the cool summer of 1907 in THE LANCET of Sept. 14th, p. 783, leads me to draw your attention to some remarkable figures in the Registrar-General's weekly return of births and deaths in London, &c., for the thirty-sixth week of the years 1906 and 1907. I refer especially to Table 3, from which it appears that in the 13 weeks ended Saturday, Sept. 8th, 1906, diarrhœal diseases were responsible for 2588 deaths in London. On the other hand, in the 13 weeks ended Saturday, Sept. 7th, 1907, this group of diseases caused only 334 deaths. The salient meteorological facts for the two corresponding periods are as follows:—

	1906.		1907.
Mean temperature of the air ...	63·4°	...	58·7°
Mean relative humidity per cent.	70·0	...	74·0
Rainfall in inches	5·43	...	5·46
Registered sunshine in hours ...	732·1	...	521·6

It will be observed that the rainfall was about the same in the two years. The number of rain days was, however, 42 in 1907 compared with only 22 in 1906. Can we doubt that the lower temperature of the air in 1907, amounting to nearly 5 degrees Fahrenheit (4·7°), the showery weather, and the comparative infrequency of blazing sunshine were the chief meteorological causes of the lower mortality from diarrhœal diseases during the past summer?

It is well known that the victims of "summer diarrhœa" are for the most part young children. We are not surprised to find accordingly that in the hot, dry, sunny season of 1906 no less than 2463 out of the total deaths from diarrhœal diseases in London (2588 in number) were of children under five years of age. In the cool, showery, cloudy, and breezy summer of 1907 281 out of 334 deaths referred to diarrhœal diseases were of children under five years. The percentages represented by these numbers are 95·2 and 84·1 respectively. From these figures it will be seen that not only were the total deaths from diarrhœal diseases in 1907 but little more than one-tenth of those which occurred in 1906, but that young children escaped comparatively in the present year from the ravages of what was a very pestilence in 1906.

The same story may be told of all the 76 "Great Towns" of England and Wales, the vital statistics of which are discussed by the Registrar-General in his "Weekly Returns." For example, the diarrhœal deaths in those towns were 2342 in the thirty-sixth week of 1906. They were not one-tenth as numerous in the thirty-sixth week of 1907, being only 229. In his annual report on the health of the borough of Southend-on-Sea, that very able and dauntless medical officer of health, Dr. J. T. C. Nash, assigns good reasons for believing that it is the effect which the prevailing weather has on the propagation and movements of flies which controls the prevalence and fatality of diarrhœal diseases among young children in summer.

I am, Sirs, yours faithfully,

JOHN W. MOORE, M.D. Dub., D.Sc. Oxon., D.P.H.

Dublin, Sept 16th, 1907.

LANCASHIRE SANITATION.

To the Editors of THE LANCET.

SIRS,—I quite agree with your leading article headed "Lancashire Sanitation," but I would point out that the Public Health Act of 1875 is responsible for the privy-middens. An attempt was made here a few years ago to revise our by-laws and one suggested alteration provided that all new houses about to be erected should have water-closets fitted instead of privies. A draft was sent to the Local Government Board and we were informed we could not insist on the general adoption of water-closets without an Act of Parliament. Section 35 of the Public Health (1875) Act reads, It shall not be lawful newly to erect, &c., without a sufficient water-closet, earth-closet, or privy. Surely you do not contend that all the local authorities mentioned in your article ought to go to Parliament for powers.

I am, Sirs, yours faithfully,

Hindley, Sept. 16th, 1907. *J. CHRONNELL.*

SUPERNUMERARY DIGITS AND A HISTORY OF HEREDITY.

To the Editors of THE LANCET.

SIRS,—Monstrosities taking the form of supernumerary digits are not of particularly rare occurrence, but I venture to think that the history of heredity in the following case is worthy of record. An infant of six weeks was brought to me for the removal of a supernumerary digit of the right hand. This finger was perfect as to the nail and terminal phalanx but the rest was represented by a fleshy pedicle of

Agent for the Advertisement Department in France—J. ASTIER, 31 ents, Asnieres, Paris separate rooms where the sections held their meetings. The official languages were English, French, and German. The Dutch physicians generally preferred to speak French but most Amsterdamers seem to know German better. The Dutch are good linguists and often speak English fluently.

SECTION I.—PSYCHIATRY.

The Function of the Cerebellum.

In Section I. Dr. VAN RIJNBERK (Rome) defended Luciani's view of the functions of the cerebellum against the criticisms of Lewandowsky.

Dr. MUSKENS (Amsterdam), who had studied the structure and function of the cerebellum for ten years, gave a lantern demonstration of the degenerations which he had observed after the removal of the flocculus in the rabbit and cat. No degeneration was found in the corpus restiforme and spinal cord, which was in accord with the views of Ferrier, Turner, and R. Russell. There was coarse degeneration of the middle third of the superior crus cerebelli, and a number of internucleal fibres going towards the other side of the cerebellum were also degenerated. Dr. Muskens was not sure that an exact knowledge of the function of the cerebellum had been reached. What was observed after loss or removal of this great organ was an impairment of the regulation of voluntary movements which affected the hemisphere of the cerebrum on the opposite side.

Dr. RAMON Y CAJAL (Madrid) gave a demonstration of the Traumatic Degeneration of the Axis Cylinders of the Brain and Cerebellum.

Professor JELGERSMA gave a lantern demonstration of a large series of Sections of the Brain and Cerebellum.

The Evolution of the Central Nervous System.

Dr. W. H. GASKELL (Cambridge) contributed a lecture on the Evolution of the Vertebrate Central Nervous System, in which he advanced the proposition that as brain power was the leading factor in all upward progress the vertebrate must have arisen from that invertebrate group which possessed the highest central nervous system evolved up to that time—viz., the arthropod group. This, he affirmed, was borne out by geological evidence.

Dr. F. W. MOTT (London) delivered a lucid address, accompanied by lantern slides, on the Development of the Sensory Areas, beginning from the lemur and ascending to the human brain. Very interesting was his statement that he could at once distinguish between microscopic sections of the visual, olfactory, auditory, and general sensory areas. As exhibited by his lantern views the structure of these areas had little dissimilarity and afforded no indication of their varying specific capacities.

Dr. MOTT, in a paper on

Chronic Alcoholic Psychoses,

also gave the result of his extensive studies in the wards and post-mortem rooms of the London hospitals and asylums. He pointed out the great variations in the estimates assigned in the statistical tables of asylums for alcohol as a cause of insanity, ranging from 20 to 8 per cent. In some cases alcohol acted directly upon the brain, as in delirium tremens. In other cases that drug had to act upon a brain already predisposed to insanity, when it might be a coefficient cause; but the incidence of drunkenness did not keep pace with the incidence of insanity. Dr. Mott made much use of the observation that cirrhosis of the liver, admitted to be due to over-indulgence in alcoholic drinks, was common with the sane patients in the London hospitals, while it was very rare in the asylums. But if insanity be so often caused by over-indulgence in drinking, cirrhosis should also be frequent with the insane. Abuse of alcohol had a direct effect in producing gastritis and liver disease; but though it rapidly acted upon the brain, its bad effects were not so permanent. Thus, though drunkenness was sometimes a coefficient cause of insanity, it seldom stood alone as a single efficient cause. It often happened, as also pointed out by Dr. P. SCHRÖDER (who followed Dr. Mott), that the sinking into drunken habits was but a symptom of the depressed and degenerate state which formed the beginning of insanity induced by other causes.—Dr. D. ORR (Prestwich) and Dr. R. G. ROWS (Lancaster) gave a lantern demonstration of lesions of spinal and cranial nerves experimentally produced by toxins.

Hysteria.

There were lively discussions between the French and German physicians on the nature of Hysteria, a subject well fitted for debate and likely to continue so. Dr. JANET (Paris), who is an eloquent speaker, considered hysteria to be a mental malady, which came into the domain of psychiatry, and therefore it should be studied after the methods of this department of medicine, and compared with other known mental diseases. He mentioned the scene where Lady Macbeth seemed to be washing her hands to rub out the spot of Duncan's blood. Such passages of somnambulism, Dr. Janet said, were not infrequent with hysterical women. Out of 660 patients observed Dr. Janet had noted at least 120 cases in which the patients at certain times repeated a scene at which they had already assisted, or put into action a fixed idea. In this state there were often hallucinations of the senses, very intense, and sometimes crimes had been committed. As long as this state lasted the subject believed nothing, accepted nothing which was in opposition to his dominant idea, as was observed in systematised delirium; indeed, he saw nothing and heard nothing out of the system of images connected with the main idea. This system of images and of movements, escaped from the control and even from the knowledge of the other systems, made up his personality. He observed that suggestion should be regarded as a consequence of this disassociation of ideas and the contraction of the scope of consciousness in the mind of the hysterical patient. Hysteria, he said, belonged to the large group of depressive psychoses, together with those suffering from melancholia and depressed maniacal delirium or psychasthenia, to which latter form it approached nearest. Thus the French only allowed a mental basis to hysteria. Some authors laid especial stress upon the mood of the hysterical patient; others upon the mental representations. Some regarded auto-suggestion as the principal factor in hysteria. Charcot remarked that hysteria might simulate anything. Bernheim observed that there were no hysterical symptoms, only hysterical attacks. Hysteria was not a morbid entity. Some German physicians, as Breuer and Freud, found the origin of hysteria in affections of a sexual nature before puberty, colouring the memory and inspiring strange intellectual conceptions.

Professor JELGERSMA made some pregnant remarks upon the Stigmata of Hysteria (such as paralyses, contractures, and anæsthesias). These were, he held, not the result of purely mental representations but of isolated mental images the outcome of a defective hereditary disposition of the central nervous system.

Professor ORSZANSKI (Charkow) in a well-written communication on the Genesis and Nature of Hysteria, argued that this disease could not be reduced to mental phenomena. Neither suggestion nor auto suggestion would explain all its multiform bodily symptoms. In hysteria not only the higher psychical faculties but the whole nervous system, the entire organism, was affected. Besides the hysterical attacks there were varieties of pathological reflexes, tremors, coughing, vomiting, and locomotor and trophic disorders. The starting point was most frequently to be found in the female genital organs. Slight affections of the uterus in some subjects were followed by hysterical symptoms, while they might not occur with much graver diseases such as tumours. In severe lesions the reflexes might be abolished, while in the lesser ones they were stimulated. Professor Orszanski called especial attention to a characteristic feature in the diagnosis of hysteria. The patient might go through severe and long-continued attacks without exhibiting the least trace of fatigue, whereas after epileptic attacks there was a period of profound exhaustion. He regarded the hysterical fit as a relief from the accumulation of energy naturally followed by a feeling of freedom and lightness which in some cases was noticeable.

Dr TERRIEN (Nantes) observed that suggestion or auto-suggestion might be the exciting cause of hysteria, but it did not create it; one was born hysterical as one was born with the gouty or syphilitic diathesis. He had met with a neurotic heredity in all his patients. This disposition to hysteria might remain latent and be kept in check by a wise physical and moral hygiene, or it might be aroused by overstrain, intoxication, or moral shocks. The accidents of hysteria might be cured but the proclivity remained. Dr. Terrien said that he could cite 20 or 30 instances of patients whom he had cured of their paralysis or hysterical contractures and who were in the enjoyment of good health, but with whom nevertheless he could produce the same old affections by suggestion. The reason of this was that the hysteria remained latent in their constitutions. On the other hand, he had tried to produce paralysis and real proof, that mollities ossium is the result of suprarenal inadequacy.

There thus appears to be evidence that in some instances pathological changes in the cortex of the suprarenal glands, whether in the direction of hyperplasia or of imperfect development, are associated with similar conditions of growth generally and especially of the genital organs.

2. *The question whether the suprarenal cortex has the power of neutralising toxins* is a subject about which very little is known and on which it is dangerous though attractive to speculate. It was formerly thought that the suprarenal bodies destroyed effete blood pigment, but this conception has been given up for want of proof. That the cortex may exert antidotal properties is suggested by Myers's[12] observations that cobra poison after being mixed with an emulsion of the suprarenal cortex was no longer toxic, control experiments with emulsions of the suprarenal medulla and of other organs being negative. Experimental infections with various organisms, such as bacillus tuberculosis, slow diphtherial intoxication, and lead poisoning (Gouget[13]), have been found to give rise to hypertrophy of the cortex of the adrenal glands, thus suggesting increased functional activity. It may be mentioned incidentally that, according to Mulon,[14] the histological evidence of over-activity (*hyperépinéphrie*) of the cortex is increased pigmentation and diminished fat in its cells.

Adenomas or nodular hyperplasia of the suprarenal cortex are found in a certain number of necropsies. In 6200 necropsies at St. George's Hospital, London, adenomas were present in 11 cases, or 0·2 per cent. (Hodge), and at Guy's Hospital in 0·7 per cent. of necropsies (Richards). They are sometimes found in cases of chronic pulmonary tuberculosis, but special attention has been drawn to the association of cortical adenomas with granular kidneys and high blood pressure, and it has been pointed out that they are rare in cases of chronic nephritis with low blood pressure. There would therefore appear to be some relation between their presence and high arterial blood pressure; as the cortex does not contain any pressor substance it cannot be held that the cortical hyperplasia causes the increased pressure, and it has been suggested that the adenomas are evidence of an attempt on the part of the cortex to neutralise the toxins responsible for the high blood pressure (Aubertin and Ambard[15]). As bearing on this it may be mentioned that it is stated that experimental lesions of the kidney lead to hyperplasia of the adrenals (Darré[16]). The main interest of the speculation as to the existence of antitoxic function in the cortex of the adrenal glands is in connexion with the pathogenesis of Addison's disease. The low blood pressure and extreme asthenia in that disease can be satisfactorily explained as due to an absence of adrenalin or the pressor substance provided by the medulla, but the vomiting, gastro-intestinal disturbance, and the pigmentation suggest irritation of the sympathetic. This has, in the past, usually been attributed to invasion of the adjacent sympathetic by inflammatory changes and adhesions, or to mechanical stimulation of these nerve plexuses by tuberculous masses in the adrenal glands, but this explanation breaks down for cases in which the adrenals are only atrophied. To meet this objection it has been supposed that the absence of adrenalin leads, by perverted metabolism, to a toxæmic state, and that this toxæmia accounts for the irritative manifestations. On the other hand, Addison's disease might be regarded as the outcome of total suprarenal inadequacy—namely, of (*a*) medullary inadequacy which, by the absence of adrenalin, accounts for asthenia and low blood pressure, and of (*b*) cortical inadequacy, which accounts for the irritative symptoms by failure of an antitoxic function exerted by this part of the organ. It is conceivable that, owing to destruction or atrophy of the cortex, there is no longer neutralisation of toxic bodies and that these accumulate and irritate the sympathetic. In this connexion it may be pointed out that the widespread distribution of pigmentation is more readily explained by a general toxæmia than by a local irritation of the sympathetic. It may also be urged in favour of this hypothesis that it explains why suprarenal extract so commonly fails to cure Addison's disease in the same way that thyroid extract counteracts myxœdema; for although suprarenal extract provides the wanting adrenalin, the extract of the cortex, even when given, is not necessarily the equivalent of the activities of the living cells of that tissue.

3. *That the cortex is in some way concerned with the internal secretion of the medulla.*—Although it does not contain any pressor substance, it is conceivable that the cortex plays an essential part in the early stages of the formation of adrenalin and that the process of elaboration is completed in the medulla, in which part alone the full activity of the secretion is acquired. In favour of this hypothesis Schäfer and Herring[17] point out the analogy between the pituitary and the suprarenal glands. In both, the glandular epithelial parts (anterior lobe and cortex) are inactive, while the neuro-ectodermal parts (infundibular portion and medulla) yield a highly active extract. The close anatomical relation of the epithelial and neuro-ectodermal parts in the two glands suggests that their physiological relation may be equally close.

We have thus seen that three views at least have been put forward as to the function of the cortex: (1) that it is connected with growth, especially of the sexual organs; (2) that it is antitoxic; and (3) that it plays some part in the elaboration of the internal secretion of the medulla. *A priori* it would appear improbable that the cortex discharges all these three functions, but from experiments on animals Marrassini[18] has put forward the view that the three zones of the cortex—zona glomerulosa, zona fasciculata, and zona reticularis—have different functions; this is little more than a suggestion, but it shows the need of waiting for further investigation. The most definite point about the cortex would appear to be that it is co-related with sexual growth.

THE MEDULLA.

The cells of the medulla provide a pressor substance—adrenalin—which acts on the sympathetic nerve endings. These cells, called chromophil or chromaffine from their affinity for chromic acid, are not confined to the medulla of the suprarenal glands but are found elsewhere in contact with the sympathetic, as Zuckerkandl's parasympathetic bodies, the inter-carotid gland which has been described as an accessory medullary adrenal (Mulon[19]), Luschka's coccygeal gland, and some collections of cells in the pituitary body. The medulla of the suprarenals therefore forms the most conspicuous part but not the whole of what has been called the hypertensive glandular system. The importance of this conception is that it explains why cases with destruction of the medullary portions of the adrenals do not always manifest the symptoms of Addison's disease, the remainder of the chromaffine system being sufficient to supply the required amount of adrenalin; conversely in some cases of Addison's disease in which the medulla of the suprarenals is not obviously affected, the hypertensive system, as a whole, may conceivably be deficient. The possible pathological relations of the internal secretion of the medulla may be divided into (I.) alteration in quantity, (*a*) absence, (*b*) diminution, and (*c*) excess; and (II.) alteration in quality.

I. *Alteration in quantity.*—(*a*) Complete absence of the internal secretion is met with in Addison's disease as is proved by the inactive condition of the medulla when tested physiologically. It has also been shown that the suprarenal medulla may be devoid of adrenalin in patients dying from chronic exhausting diseases, and that though there is often obvious naked-eye change in the glands, this is not an invariable accompaniment of the loss of functional activity (Mott and Halliburton). As bearing on the interesting question whether there is normally an equilibrium between the pressor or hypertensive internal secretions of the medulla of the suprarenals and of the other collections of chromaffine cells on the one hand and the depressor internal secretion of the thyroid on the other hand, it may be pointed out that in Addison's disease a relative excess of the internal secretion of the thyroid might be expected on account of the absence of adrenalin. There is, however, no evidence of this in Addison's disease; there above the symphysis, or in which a prostatic hæmorrhage was a vital indication. At any rate, it was the duty of the surgeon to explain to the patient that a prostatectomy was connected with great risk, would surely cause impotence and possibly psychical derangements, and that he would perhaps be obliged to renew or to continue his "catheter life," notwithstanding the operation.

Later Professor TSCHERNING (Copenhagen), Dr. BORCH GREVINK (Christiania), and Dr. LENDORF (Copenhagen) partook in the discussion.

Professor WESTERMARK (Stockholm) reported shortly on some observations made by him in cases of delivery under spinal anæsthesia, going to show that the corpus uteri had no nervous supply, the contractions depending on properties which appertained to the muscular fibres alone.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE holidays are now almost at an end and the winter session will commence on Tuesday, Oct. 1st. In the medical faculty a conversazione will be held on the evening of that day when the various departments and laboratories will be open for inspection by the guests of the dean and medical faculty, and on the following day the ordinary routine work of the session will begin. The work of the session, however, will be preceded as usual by the September examinations in the second and third parts of the professional course in medicine—that is, in biology, anatomy, physiology, and in materia medica and pathology. This year also at the same time there will be an examination in anthropology and physiology for science students; thus in reality the work of the school will recommence before the winter session actually opens. There is every prospect of a good entry in all the departments of the University and it is hoped that the records established last year will be surpassed, for the influence of the various sections is rapidly extending and students from widely separated parts, both of the old and new world, are applying for admission. The accommodation for the students of engineering, metallurgy, and mining in the new buildings at Bournbrook is now in full working order, and the departments are equipped not only with all necessary apparatus and specimens but also with sectional libraries, which greatly facilitate study and reference. The additional blocks at Bournbrook intended for chemistry and physics are growing rapidly, but it is scarcely likely that they will be ready for occupation during the next two years, yet such a period in the history of an institution is comparatively short and the authorities will soon have to consider how the first year of the medical course is to be remodelled, so that the medical students shall not be placed at a disadvantage when chemistry and physics leave Edmund-street for their new homes at Bournbrook.

Measles in the Midlands.

During the present year many parts of the Midlands have suffered from measles and in all the places attacked the disease has been severe and associated with complications from which many deaths have resulted. During the first six months of the year Birmingham was one of the places attacked, but apparently, at last, the epidemic in the city is over and the number of cases has fallen to the usual level. Dudley has not escaped the epidemic. During the ten weeks ending August 24th last it was the cause of 25 deaths in that town and though the disease seems to be subsiding it is still prevalent in several wards. In Tunstall the attack commenced in January in the south of the town and extended along its western side towards the north. Apparently it has now ended, in its epidemic form, after a secondary outbreak in the streets of the western side. In the Sedgley and Oldbury districts it is still present in the epidemic form and in the latter district it has caused 15 deaths during the past month. There can be little doubt, as the medical officer of Tunstall has pointed out, that the excessive mortality of the attack has been largely due to the severity of the disease and the frequency of lung complications, associated with the fact that the epidemic was worst in the most densely populated areas where faultily constructed houses and want of intelligent nursing are so commonly met with.

New Isolation Hospital for Smethwick and Oldbury.

At the opening of the new isolation hospital which has been erected by the Smethwick town council and the Oldbury district council Mr. J. W. Wilson, M.P., congratulated the authorities on the good sense which they had shown in adopting a joint scheme whereby money had been saved both by Smethwick and by Oldbury. He stated that much of the ratepayers' money was often wasted by local authorities who would not enter into joint schemes with their neighbours. There is much truth in this statement and certainly Smethwick and Oldbury, though they have only carried out part of the original scheme, have succeeded in erecting excellent accommodation for isolation purposes, conveniently situated for both, at what may be looked upon as a comparatively small cost of £19 524, of which Smethwick will pay £13,436 and Oldbury £6088. In its present condition the hospital includes a pavilion of 16 beds, an observation, a discharging, and an administrative block. In the meantime the hospital will be used for the isolation of scarlet and typhoid fever cases, and ultimately when the scheme is completed 68 beds will be provided.

Past and Present Health of Birmingham.

Alderman Sir William Cook gave some very interesting information the other day concerning the past and present health of the city when speaking in association with a lecture by Dr. R. A. Lyster on the Health of Children. He pointed out that 30 years ago the death-rate was 25 per 1000, whilst in the last three years it has been reduced to 17 per 1000, a result due most probably to the adoption of improved sanitation and to the diminution of overcrowding. We can scarcely congratulate ourselves as yet that it is due to the spread of knowledge conducive to health and application of that knowledge to any great extent amongst the poorer classes, for, as Sir William Cook stated, during the period in which the total death-rate has been reduced one-third the infantile death-rate has only fallen about one-twentieth—that is, from 176 to 167 per 1000. This year, however, we may eventually have a better record in this respect, for, thanks to the cold wet summer the deaths from summer diarrhœa have been comparatively few in number, and during ten of the latter weeks only 56 deaths have occurred from this disease as contrasted with 479 in the corresponding weeks of 1906. In spite of the severe epidemic of measles in the first part of the year the total death-rate of 1907 promises to compare well with that of the immediately preceding years, though it can scarcely be hoped that it will be much reduced beyond the low level at which it now stands until some means are found of effectually combating the infantile death-rate and the loss caused by epidemic diseases. So far as measles is concerned Sir William Cook stated that a scheme is being worked out between the health department and the education department by means of which it is hoped that the spread of measles amongst the scholars in elementary schools will be reduced. Scarlet fever, however, seems to defy the efforts of the health department; it is still far too prevalent in the city, and until some new means of checking it are discovered the five-yearly waves intend apparently to run their usual course, and in that case, as Sir William Cook pointed out, we have not yet reached the summit of the present wave and may expect that the number of cases will continue to rise until next year. Whilst the cold wet summer has had a favourable effect upon summer diarrhœa, the inclement weather of the year seems to have produced an opposite result in the case of consumption, for in a corresponding period the number of deaths has risen from 463 to 491, in spite of the precautions and efforts of our active medical officer and his assistants.

Sept. 17th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Health of Liverpool: Corporation Hospitals.

THE port sanitary and hospitals committee of the city council made a complete tour of the corporation hospitals on Sept. 5th, the visits to the six institutions occupying over ten hours. Invitations had been issued to the chairman of each standing committee and others specially interested to join in the inspection. The officials with the party included the medical officer of health (Dr. E. W. Hope) and Dr. A. A.

giving adrenalin by the mouth in cases of pneumonia in adults and in bronchopneumonia in children, and, I believe, with good results; it has appeared to prevent cardiac failure and has not given rise to any bad symptoms such as œdema of the lungs. Another objection raised against this use of adrenalin is that experimentally it produces arterial degeneration; as bearing on this I have examined the aorta in a few cases in which adrenalin had been given during life and have not found any recent changes. But I do not lay any stress on this for several reasons—my observations are quite insufficient, the amount and duration of the administration of adrenalin were not comparable with those employed in the experimental degeneration, and even if recent changes were found it might be argued that they were due to toxins of the disease responsible for death. While I believe that adrenalin is a valuable circulatory tonic in acute infections, especially pneumonia, I am anxious that this point should be more thoroughly tested, especially as I have found but little increase in the blood pressure of febrile patients showing apparent improvement while taking adrenalin.

(3) Relative inadequacy of the internal secretion of the medulla. By this is meant that if there be normally a balance between the effects of the pressor and depressor glands, any excessive secretion (depressor) of the thyroid should lead, the pressor secretion maintaining the normal mean, to a relative deficiency of the antagonising internal secretion. The question that arises here is whether the symptoms of thyroidism, of exophthalmic goitre, and the allied toxic manifestations which, as Sir Victor Horsley[27] points out, may sometimes be seen in ordinary goitre are in any degree due to a relative deficiency in the secretion of adrenalin. It is clear from Janeway's[28] summary that the blood pressure is not low in exophthalmic goitre, as might naturally be expected if the disease be regarded as due to simple hyperthyroidism, and that it may be very considerably raised as the result of psychical excitement. In the few cases in which I have taken the blood pressure with a Riva-Rocci sphygmometer it has been rather above than below the normal. It is true that in some cases of exophthalmic goitre improvement has followed the administration of suprarenal extract; I have seen this myself. But it must be remembered that exophthalmic goitre often improves both spontaneously and after widely different forms of treatment, and that it has not been shown that suprarenal medication is a certain means of counteracting the symptoms of exophthalmic goitre. We have therefore no evidence that an excess of thyroid secretion produces bad effects by means of a relative deficiency in adrenalin.

(c) Excessive secretion of adrenalin. Here, again, very little is known. The excess might conceivably be (1) due to an excessive secretion of adrenalin by the medulla, or absolute excess, or (2) be relative and depend on a diminution in the amount of the thyroid secretion. (1) Since the demonstration that atheroma can be artificially produced in animals by the injection of adrenalin (Josué,[29] Pearce and Stanton,[30] and others) the question has arisen whether high arterial blood pressure in man and its results—hypertrophy of the left ventricle, arteriosclerosis, atrophic changes in the kidneys, and so forth—may be due to an excess of adrenalin in the circulation. As it is generally believed that in renal disease a raised blood pressure is, within limits, useful, it might be assumed that this compensatory process is brought about by hyperplasia of the suprarenal medulla. Let us see how the evidence available bears on this question. From some experiments on animals Marrassini[31] concludes that interference with the renal excretion increases the functional activity of the medulla. A case of parenchymatous nephritis with great hypertrophy of the left ventricle and manifest hyperplasia of the medulla of the suprarenals has been reported (Vaquez and Aubertin)[32] and might be taken to support this view. But as regards this special form of renal disease this would appear to be almost an isolated observation. Wiesel[33] has recorded a number of cases of high blood pressure, arteri sclerosis, and granular kidney, associated with enlargemen of the suprarenal medulla and also of the chromaffin cells in the solar plexus. Here it might at first sight b thought that the suprarenal change was the cause of th high blood pressure and of the structural changes, as i experimental atheroma. It has, it is interesting to not been suggested (W. Russell)[34] that certain foods, especiall proteins, may lead to increased secretion of adrenali It would thus be possible to construct a hypothesis c dietetic excess, absorption from the intestine of tox bodies which stimulate the medulla of the suprarenals t increased functional activity followed by hypertrophy, an that subsequently the cardio-vascular changes are produced But Wiesel believes that the cardiac hypertrophy precede the hyperplasia of the suprarenal medulla and is not due t it. This relation between the sequence of events must b somewhat difficult to determine and the subject is in need o further study. At present there is no proof of the existenc of any disease due to excessive adrenalin secretion an corresponding to exophthalmic goitre in the case of th thyroid, but on this point we must be content to wait fo further information.

(2) Relative excess due to a deficiency in the amount o antagonising depressor internal secretion. It is conceivabl that, as the result of the atrophy of the thyroid which s commonly accompanies advancing years, the equilibriu normally existing between the internal secretions of th thyroid (depressor) and of the adrenal medulla (pressor would no longer be maintained and that an excess o adrenalin would therefore accumulate in the circulation an thus induce a correspondingly high arterial pressure. I other words, that the rise of arterial blood pressure as lif advances is due to a predominance of the pressor internal secretions. In support of this it might be urged that i myxœdema it is common to find arterio-sclerosis an granular kidney, which may result from long-continued high blood pressure; but too much stress must not be laid on this, for the age of myxœdematous patients approache that at which vascular degeneration is common, and in a certain number of cases of myxœdema the kidneys ar healthy.

To return again to the question whether the hypothetical equilibrium between the depressor and pressor internal secretions may be upset by a deficiency of one, so that the other secretion has a paramount influence, Gioffredi's[35] conclusions are to the effect that normally certain organs and tissues—the liver, the blood, and to a less extent the voluntary muscles—transform adrenalin into an inactive product and so protect the body against the toxic results of an excess of adrenalin which might otherwise result. In order to effect this change the blood must be provided with oxygen and be alkaline, but those conditions are not necessary in the case of the liver and voluntary muscles. It is conceivable that such a compensatory mechanism might fail under the same conditions as those under which the thyroid secretion wanes, and that then a relative excess of adrenalin in the circulation would result. These considerations are highly speculative, but they may perhaps be forgiven because they bear in a somewhat remote manner on an important practical point—namely, the prevention and reduction of the rising arterial pressure of advancing years. For they suggest that the administration of thyroid extract might have this desired result and that it may prove to be the routine treatment. Iodides, which are so widely given in clinical medicine in order to lower blood pressure, have been shown to have no depressing effect on the heart or blood pressure (Stockman and Charteris[36]), but it is conceivable that they eventually lower blood pressure by stimulating the thyroid to an increased secretion.

II. *Alteration in quality.*—Of alterations in the quality of secretions very little is known if we except the gastric juice, but it is reasonable to believe that in the future this factor will attract attention and be shown to have most important pathological bearings. The adenomatous changes in the thyroid in exophthalmic goitre and in the pituitary body in acromegaly may safely be assumed to lead to an altered internal secretion, and so to have a causal bearing on the associated diseases. In the case of the adrenal medulla nothing is known as to any alteration in the quality of the secretion. It is somewhat addition. The necessity which impelled the managers of the infirmary to divest themselves of the school buildings and of any share in the management of the medical school was that in Scotland extra-mural teaching was declining owing to Scotchmen in growing numbers becoming determined, when they entered the medical profession, to enter it through the university and owing to the establishment of new colleges and universities in England where medicine was taught. Thus the managers of the infirmary came to the conclusion that only by their medical school becoming a college of the University of Glasgow under the provisions of the Universities Act could medical students be attracted to the Royal Infirmary. In appealing to the public for funds the governors of the college have always urged that the college existed primarily to advance the interests of the Royal Infirmary by securing clinical students for its wards as clerks and dressers and that such attendance of students was requisite to maintain the great traditions of the Royal Infirmary. The early appeals were generally made by the joint authority of the governors of the college and the infirmary board. In the Diamond Jubilee year a fund was opened for rebuilding a portion of the Royal Infirmary as a memorial of Queen Victoria. Subsequently it was decided that the whole infirmary should be rebuilt, and for this purpose appeals for a large fund were made to the public. The governors of St. Mungo's College resolved that in the circumstances they should hold their hands in the way of asking for money. But about three years ago, owing largely to the effect of Mr. Carnegie's gifts to the universities, the number of extra-mural medical students had so much further declined that the governors found themselves confronted by serious financial difficulties. It became apparent that only by the step of raising a sufficient fund to warrant the governors in approaching the Privy Council with a view to have the college declared a college within the meaning of the Universities Act as the first procedure towards university affiliation could these difficulties be met and the primary object of the college—namely, to afford to the Royal Infirmary a sufficient number of clinical students—be carried out. This was communicated to the managers of the infirmary who were asked to assist the college in making a representation to the public. Prolonged negotiations thereupon took place between the governors and managers of the two institutions which culminated in the joint meeting of last week. The final decision of the managers of the infirmary is that they will not bear any part in raising funds to bring about the affiliation of the college on its existing basis. It emerged in course of the discussion that the managers generally are of opinion that a complete school at the Royal Infirmary is unnecessary and that students from the university at Gilmorehill might be to some extent induced to attend the classes of the final year of the medical curriculum at the Royal Infirmary and thus provide a sufficient number of clinical students for the wards.

Dundee Royal Infirmary.

A meeting of the governors of the Dundee Royal Infirmary was held recently. Mr. J. W. Fleming, who presided, reported that the gynæcologists and surgeons were now finding ample room for carrying out the donor's intentions, not only in respect of cancer but also of other surgical ailments, in the new buildings provided by Mr. J. K. Caird. He also expressed the hope that when the arrangements now in progress for the special investigation of cancer were complete the desire of the donor to throw light on the disease would be fulfilled. The municipal dispensary for consumption had now been at work for several months in the out-patient department and the results were likely to prove of great value. Difficulty had been found in dealing with patients in the wards who were in the advanced stages of consumption and he thought that the provision for those cases which were a real source of danger to the community should not fall on a charitable institution but that the cases should be dealt with by the authorities under the Notification of Infectious Diseases Act. The meeting approved of a scheme for the extension and better equipment of the laundry, for improving the internal arrangements between the main block and the cancer hospital, and for providing additional accommodation in the out-patient department to enable the medical officers to carry on their work with greater convenience. It was announced that the improvements would cost £1570.

Aberdeen District Lunacy Board.

The monthly meeting of the Aberdeen District Lunacy Board was held last week. A motion to reconsider the duties and salaries of the medical superintendent, stewards, matron, grieve, and gardener was defeated by a large majority. A motion to pay the standard rate of wages in connexion with all jobs given out by the district board was also defeated. The cost of Kingseat Asylum to date is £132,121.

Enteric Fever at Peterhead.

The medical officer of health of the burgh of Peterhead reports that the number of cases of enteric fever notified to him during the past week was eight. Nine cases have been removed to the hospital and 13 have been dismissed well, while one death has occurred. 46 cases still remain in hospital.

The Fishers' Dispensary at Aberdeen.

The dispensary which is carried on at Point Law for the treatment of surgical cases among the fisher-people was closed last week. The number of dressings done during the season just ended was 1135 and the number of patients 345. Of this number 121 were fishermen and coopers and 224 were curing women and girls. The dispensary is open only during the herring-fishing season of each year.

The Tuberculosis Exhibition.

THE secretary of the National Association for the Prevention of Tuberculosis, Dublin, has written to the medical superintendent of the White Abbey Sanatorium for Consumptives, which was founded by the Belfast board of guardians, soliciting his aid in the formation of the proposed Tuberculosis Exhibition in Dublin. The matter came up for consideration at a meeting of the Belfast guardians on Sept. 11th, when it was decided to procure and to forward a number of photographs of the abbey for the exhibition.

The Local Government Board and the Belfast Health Authorities.

The auditor of the Irish Local Government Board has reported to the finance committee of the Belfast corporation that he has disallowed the expenditure of £10 10s. incurred for the printing of posters issued by the Belfast public health committee in reference to physical degeneration. He says that the representative of the Belfast and Ulster Vintners' Association attended when he was going into the accounts and objected to such an expenditure. I append the editorial comments of one of the leading Irish papers, the *Northern Whig* of Sept. 17th, on the matter :—

> Does the Local Government Board suggest that the city council is not legitimately interested in the health of the city, and that it would be illegal in the case of a visitation of cholera, typhoid, or small-pox for the corporation to spend money in advising the people to look after their drains, water-supply, and backyards? It appears that it was the publicans who objected to the posters, from which we conclude that they dealt with the evils of intemperance. But we have always been told that the licensing interest was itself hostile to intemperance and anxious to check its ravages Yet it appears that the trade and the Local Government Board now join hands in their objection to temperance placards. Perhaps the Board will take the trouble to explain its action in this matter, so that we shall know in the future whether it is really forbidden for the corporation to spend money in promoting public health.

(FROM OUR OWN CORRESPONDENT.)

The Appointment of a Communal Medical Officer Declared Illegal.

A SINGULAR incident in connexion with medical practice has occurred in a commune in the department of Haute Garonne. As there was no medical man in this commune an attempt was made to induce one to settle there by offering him a fixed salary for several years. Several persons who would in the usual course have to contribute to the expense thereupon asked the Council of State to declare this offer illegal and a decision was given in their favour. The Council of State held that the law only permitted municipal councils to provide gratuitous medical aid for paupers. There might be exceptional circumstances in which it would be permissible to provide medical aid for persons who had no objections. One objection was that the breeding waters must be so numerous that their suppression would be too costly an undertaking, even in towns; and those who held this view forgot that to exsiccate a town would generally be a far less formidable engineering task than to give it a pipe water-supply or a sewerage system, while in dry climates it might prove a very easy task indeed. Another objection, and a still more extraordinary one, was that local *mosquito reduction* would be useless owing to the immigration of mosquitoes *from outside*. This is as much as to say that the population of an area would not be decreased by the abolition of the birth-rate within that area; but in spite of the unreasonableness of the objection it was repeated everywhere for years and did not disappear until it was dealt with mathematically, first by myself,[7] and then more fully by Professor Karl Pearson and Mr. J. Blakeman.[8] Repeated over and over again, in spite of the clearest disproof, these objections have done much to check anti-malaria work throughout the world and have also been often used, I fear, to cover the inertia or indifference of officials.

II.—CAMPAIGNS IN WEST AFRICA.

I will now proceed to describe briefly the progress of events as known to me. As already stated, in 1899 I visited Sierra Leone with two colleagues and advised the authorities exactly regarding the best means of reducing malaria in the capital, Freetown. Immediately after this visit the Liverpool School of Tropical Medicine despatched, on my advice, a number of gentlemen, Dr. R. Fielding-Ould, Dr. Annett, Dr. J. E. Dutton, and Dr. J. H. Elliott, to various West African Colonies (British Gambia, Sierra Leone, Gold Coast, Lagos, and Nigeria) in order to make similar studies. Later the Royal Society sent, also on my advice, Dr. J. W. W. Stephens and Captain S. R. Christophers, I.M.S., so that by 1901 a fairly accurate survey of the malaria was made in many towns along that deadly coast and measures for prevention were formulated.[9] In most cases it was comparatively easy to take these measures. Thus in Sierra Leone our suggestions of 1899 were not really difficult. The town contains only about 30,000 inhabitants; and though, owing to the large rainfall, to a rocky substratum to the soil, to numerous flat areas, and to the existence of many badly-constructed surface drains and gutters, there were many anopheline pools, yet almost all of these were so small that a little cutting or filling up with gravel or concrete, would suffice for their abolition. I suppose that £20,000 would have paid for the exsiccation of the whole town, with an annual maintenance expenditure of, say, £500; but a great deal of good could have doubtless been effected with much smaller funds. For example, many of the holes in the soil, which were the principal source of the anophelines, could have easily been filled up by small gangs of labourers working constantly under the local municipal engineering and sanitary departments, without any elaborate general drainage scheme. Considering that the whole prosperity of the place, long known as the "white man's grave," had been checked by the malaria, we had reason to hope that at least some serious consideration would be given to our suggestions.

For a year and a half after our departure, however, little appears to have been done. We heard that one man had been employed to treat the pools but that his services had been dispensed with later. At this time the objections to prophylaxis by mosquito reduction were being so loudly uttered by those who had not sufficiently considered the matter that I felt that the whole of this invaluable sanitary policy was in imminent danger of being lost to the world, in spite of all the arguments which had been used in favour of it. For example, so good an observer as Rogers[10] said in 1901 that "Very few authorities now consider it feasible to reduce malaria *materially by the destruction of anopheles*"; and even at the last meeting of this Congress[11] Celli remarked that while the laboratory experiments of himself and Casagrandi for the destruction of mosquitoes were encouraging, yet "in the wide field of practice the difficulties were such that we could scarcely by this means, unless in exceptional cases, obtain in our country the suppression of malaria." Fortunately at that moment (early in 1901) a Scotch philanthropist offered me £2000 to defray the expenses of giving an object-lesson in the methods of mosquito reduction. This generous gift, augmented by several friends to the cause, was accepted with gladness and gratitude, and I determined to return at once to Sierra Leone and to commence, myself, the measures which I had previously recommended. Of course it was not possible that with £2000 I could actually succeed in ridding Freetown of malaria, but I hoped at least to demonstrate the feasibility of the measures, and trusted that when they were once begun the local government would not hesitate to continue them. Accordingly in June, 1901, I left England for Freetown with Dr. M. Logan Taylor who was to carry out the work under my general instructions.

On arrival we found everything in nearly the same condition as when I had left the Colony two years previously. Scarcely any of the breeding-pools had been done away with; owing to faulty sanitation the backyards of the houses were filled with rubbish, such as broken bottles and old tins, in which innumerable mosquitoes were propagating; the hospitals were not protected with gauze; general quinine prophylaxis was not insisted upon, even among officials; and there were no trustworthy statistics to measure the actual amount of malaria present. Dr. Taylor attacked the work with great energy, employing occasionally over 50 men at a time, to which the local authorities contributed a gang of 12 men and carts and implements. A large number of breeding-pools were rapidly dealt with; innumerable cartloads of rubbish were removed from the houses; and the people were advertised of the dangers caused by mosquitoes. Although there is no known method for estimating exactly the number of mosquitoes within a given area, we felt ourselves justified in concluding from general observation that these measures had produced a marked diminution in the insects. Dr. C. W. Daniels of the London School of Tropical Medicine inspected the work shortly after its commencement and reported (Oct. 1st, 1901): "In my opinion, already your efforts have been crowned with a large degree of success, as there has been a noteworthy diminution in the number of the first two genera" (*Anopheles* and *Stegomyia*) "found in the houses. The number of breeding grounds has been enormously diminished."[12] Dr. Taylor continued the work for the whole of the next year under the varying conditions of the wet and dry seasons and used the money at his disposal to its fullest advantage. But, as I have said, with our limited funds, our attempt was intended merely as a commencement, which, it was hoped, would be followed up energetically by the local authorities with the much greater resources which they possessed—and I stated this clearly in my report on the affair. I have no doubt that if this had been done malaria would have been practically banished from the town from that date. Unfortunately, as Dr. Taylor's time grew to a conclusion, he was obliged to report unfavourably upon this point; and we therefore determined with regret to put an end to our efforts in that colony.[13] A year later the authorities roused themselves sufficiently to ask for a public inquiry into the whole matter; but as we objected that they had probably allowed all his work to fall into abeyance in the interval the proposal was quashed. At this time, moreover, the brilliant campaign at Ismailia began to develop, and there was no longer any need for private individuals to sacrifice their time and their health in the attempt to help those who were obviously not very anxious to help themselves.

In the meantime the new ideas had been gradually gaining ground, and public prophylaxis against malaria had been started with more or less vigour in several localities. Passing over, according to my intention, the German and Italian work, I will commence with that of Sir William MacGregor, M.D., Governor of Lagos, to whom belongs the honour of having been the first British governor to comprehend the full importance of recent discoveries and to act upon them. As early as 1900 he made a careful examination of the evidence upon which they were based; and, being himself a medical man well skilled in many sciences, became quickly convinced and then determined to take action at once. Lagos is an important town of West Africa, built in the midst of addition. The necessity which impelled the managers of the infirmary to divest themselves of the school buildings and of any share in the management of the medical school was that in Scotland extra-mural teaching was declining owing to Scotchmen in growing numbers becoming determined, when they entered the medical profession, to enter it through the university and owing to the establishment of new colleges and universities in England where medicine was taught. Thus the managers of the infirmary came to the conclusion that only by their medical school becoming a college of the University of Glasgow under the provisions of the Universities Act could medical students be attracted to the Royal Infirmary. In appealing to the public for funds the governors of the college have always urged that the college existed primarily to advance the interests of the Royal Infirmary by securing clinical students for its wards as clerks and dressers and that such attendance of students was requisite to maintain the great traditions of the Royal Infirmary. The early appeals were generally made by the joint authority of the governors of the college and the infirmary board. In the Diamond Jubilee year a fund was opened for rebuilding a portion of the Royal Infirmary as a memorial of Queen Victoria. Subsequently it was decided that the whole infirmary should be rebuilt, and for this purpose appeals for a large fund were made to the public. The governors of St. Mungo's College resolved that in the circumstances they should hold their hands in the way of asking for money. But about three years ago, owing largely to the effect of Mr. Carnegie's gifts to the universities, the number of extra-mural medical students had so much further declined that the governors found themselves confronted by serious financial difficulties. It became apparent that only by the step of raising a sufficient fund to warrant the governors in approaching the Privy Council with a view to have the college declared a college within the meaning of the Universities Act as the first procedure towards university affiliation could these difficulties be met and the primary object of the college—namely, to afford to the Royal Infirmary a sufficient number of clinical students—be carried out. This was communicated to the managers of the infirmary who were asked to assist the college in making a representation to the public. Prolonged negotiations thereupon took place between the governors and managers of the two institutions which culminated in the joint meeting of last week. The final decision of the managers of the infirmary is that they will not bear any part in raising funds to bring about the affiliation of the college on its existing basis. It emerged in course of the discussion that the managers generally are of opinion that a complete school at the Royal Infirmary is unnecessary and that students from the university at Gilmorehill might be to some extent induced to attend the classes of the final year of the medical curriculum at the Royal Infirmary and thus provide a sufficient number of clinical students for the wards.

The Appointment of a Communal Medical Officer Declared Illegal.

A SINGULAR incident in connexion with medical practice has occurred in a commune in the department of Haute Garonne. As there was no medical man in this commune an attempt was made to induce one to settle there by offering him a fixed salary for several years. Several persons who would in the usual course have to contribute to the expense thereupon asked the Council of State to declare this offer illegal and a decision was given in their favour. The Council of State held that the law only permitted municipal councils to provide gratuitous medical aid for paupers. There might be exceptional circumstances in which it would be permissible to provide medical aid for persons who had no

Pressat has said,[22] he was able to effect the preliminary work with a "mosquito brigade" of only four men, "qui a tout fait." Although hundreds of men were employed later for large permanent works, this was only after the mosquitoes had already disappeared "grace à notre brigade de quatre hommes." I may perhaps be pardoned for dwelling on this fact because it fully justifies the advice which I had given more than three years previously but which had been met everywhere with scepticism. The results were most striking. It should be remembered that as nearly all the inhabitants of Ismailia were employees of the Suez Canal Company, and as no other fever was prevalent in the town, exact statistics for many years had been possible. I give the following approximate figures from Dr. Pressat's works from the time when malaria first appeared in 1877 to 1905:—

Years.	Cases of malaria.	Years.	Cases of malaria	Years.	Cases of malaria.
1877	300	1887	1800	1897	2089
1878	400	1888	1400	1898	1545
1879	500	1889	1450	1899	1784
1880	400	1890	1900	1900	2284
1881	450	1891	2500	1901	1990
1882	480	1892	2050	1902	1551
1883	550	1893	1750	1903	214
1884	900	1894	1100	1904	90
1885	2000	1895	1350	1905	37
1886	2300	1896	1150		

For more exact figures I must refer to Dr. Pressat's works. Since 1904 nearly all the cases have been relapses among persons previously infected, and last year the company officially reported that "toute trace de paludisme a disparu d'Ismailia." Of course, the treatment of old cases has constantly proceeded parallel to the antimosquito campaign. But the fortunate inhabitants have been relieved not only of malaria but of the constant annoyance caused by the insects. In 1902 we were constantly being bitten in the houses. Now, as many visitors to Ismailia have testified,[23] one can sleep there without nets. This does not imply that the insects are absolutely unknown in the town, but only that their numbers have been very greatly reduced. Absolute extirpation is scarcely possible without bonification over a very wide area, but, as mathematically shown, reduction to a small percentage is much more feasible, and there are evident logical reasons for supposing that the amount of an insect-borne disease must ultimately vary *cæteris paribus* as the square of the number of the insects. The cost of the work has been officially reported[24] as being about 50,000 francs for the original drainage and filling up of the pools, with an annual expenditure of 18,300 francs for the mosquito brigade, oil, maintenance, &c. This amounts to an initial expenditure of about 6·25 francs and an annual expenditure of about 2·3 francs per head of population—a small price to pay for the benefits given.

It has been said by the opponents of mosquito reduction that the success at Ismailia was not real, but merely consisted in the statistical transfer of cases from the heading of malaria to that of other fevers consequent on better diagnosis. This is untrue as there is no other fever there. It has also been said that the success was due to the exceptionally easy conditions at Ismailia. True, the conditions are not so difficult as in places like Panama and Sierra Leone, but I have seen many areas where they were quite as easy as in Ismailia but where nothing whatever has been done. The success at Ismailia is absolutely unquestionable. It is due chiefly to mosquito reduction and also largely to cinchonisation. We owe it entirely to the intelligence and capacity of Prince d'Arenberg and his excellent staff.

IV.—CAMPAIGNS AT KLANG AND PORT SWETTENHAM.

Commenced even before the campaign at Ismailia, as ably conducted and almost as decisive, the work at Klang and Port Swettenham in the Federated Malay States is an equally distinguished example of the radical method of malaria-reduction. Klang is a town of 3576 inhabitants (in 1901), situated on the banks of the river of the same name in the State of Selangor, on a flat, swampy area lying between the river and a semicircle of low hills. In September, 1901, as the navigation of the river to Klang presented difficulties, a new port called Port Swettenham was opened five miles down the river from Klang on an area reclaimed from mangrove swamp. The population of the two settlements together was about 4000 in 1903, while that scattered through the surrounding district was about 14,000. The rainfall averages about 100 inches (three metres) a year. The full history of the campaigns in these two towns is given in the excellent papers by Dr. M. Watson, the district surgeon, and Mr. E. A. O. Travers[25], [26], [27], [28], the State surgeon. In the latter part of 1901 malaria became very serious in both towns and, according to Dr. Watson, perhaps not more than three houses in the whole of Klang escaped infection, while the workmen at Port Swettenham began to leave the place. Dr. Watson immediately set himself to collect statistics, to observe the local anophelines, and to take the preliminary steps for the campaign. Supported by Mr. Travers and the Sanitary Board and by the intelligence and liberality of the Government, he soon obtained realisation of the recommendations of himself and his colleagues made on the lines laid down by me ([26], p. 349). At Klang work was commenced in 1901 by extensive clearing of undergrowth, followed by drainage in the next year. The swamps in the town were rapidly filled in and a contour drain to intercept the inflow from the surrounding hills was cut. At Port Swettenham forest and mangrove swamp were felled and a complete drainage scheme, prepared by the State engineer, was carried out. In both towns, pending completion of the drainage, mosquito brigades were appointed; and their employment was extended subsequently under the name of "town gardeners." When the epidemic had already begun to subside (p. 353) wire gauze was supplied to many of the houses and an active quinine distribution was commenced. All the measures have been well maintained since then.

As regards cost, Mr. Travers and Dr. Watson state that at Klang it amounted at the end of 1905 to a total of £3100, with an annual expenditure of £210 for town gardeners and of £60 for clearing drains. For this money 332 acres (134 hectares) have been dealt with, including virgin jungle, dense secondary growth, and swamp. At Port Swettenham the total cost has been £7000 to the end of 1905, with an annual unkeep of £140. For this 110 acres (45 hectares) of mangrove swamp were drained, and a considerable area has been levelled, partly to provide building sites. The cost per head of population has therefore amounted to about £1 4*s*. up to the end of 1905—a very small charge considering the heavy rainfall and the dense vegetation of the country. These towns did not possess the exact statistics of Ismailia for a long period previous to the campaign. Great credit is therefore due to Dr. Watson for the care and skill with which he has determined the results of his measures.[27] The following table is compiled from the figures given by him:—

Results of the Antimalaria Campaign in Klang and Port Swettenham.

(From the *Journal of Tropical Medicine*, July 2nd, 1906, by Mr. Travers and Dr. Watson.)

Population of Klang and Port Swettenham about 4000 in 1901 and now largely increased. District population 14,000 in 1901. Antimalaria campaign commenced (only in Klang and Port Swettenham) in 1902.

1.—Cases of Malaria admitted to Klang Hospital from the Two Towns compared with those admitted from District.

Years	1901	1902	1903	1904	1905
Towns	610	199	69	32	23
District	197	204	150	266	353

2.—Deaths in Klang and Port Swettenham.

Years	1900	1901	1902	1903	1904	1905
Fever	259	368	59	46	48	45
Other diseases ...	215	214	85	69	71	68

3.—Deaths Registered in District, excluding Towns.

Years	1900	1901	1902	1903	1904	1905
Fever	173	266	227	230	285	351
Other diseases ...	133	150	176	193	214	271

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The First National Congress on Industrial Diseases.

THE "malattie del lavoro" (ailments contracted by the artisan or labourer) are becoming yearly more common in Italy, whose industrial progress, marked as it is, has its "reverse side" equally marked in the pathological sense. On Nov. 19th, 20th, and 21st Palermo will be the seat of the first congress on a national scale convened in Italy for the minimising of those "malattie" and already a strong committee has been formed to carry out its programme, strong in capacity to deal with the "patologia del lavoro" in all its aspects, medical, biological, and social. Under these several heads a number of papers are announced for reading and discussion, which, the special competency of their authors considered, cannot fail to fructify in legislation for the protection and the well-being of the working man. Dr. Giuseppe Züno, professor of legal medicine in the University of Messina, leads off with a report on "Infortunio e Malattie del Lavoro" (Labour: its Casualties and its Diseases); another important "Relazione" will be that by Dr. Eugenio Di Mattei, professor of hygiene in the University of Catania, and Dr. Francesco Spallitta who holds the chair of physiology in the Palermitan school; its subject: "L'Alimentazione delle Classi Laboratrici del Mezzogiorno" (the Feeding of the Working Classes of Southern Italy); and a third "report" will deal with "La Simulazione negli Infortuni" (Malingering or Simulation in Casualties, Medical and Surgical). This last has been intrusted to the capable hands of Dr. Domenico Mirto, professor of legal medicine in the University of Palermo, and Dr. Ciauri of the Army Medical Department. The president of the congress is Dr. Liborio Giuffrè, director of the Institute of Medical Pathology in the Palermitan School, and the general secretary is Dr. Rocco Jemma, who holds the chair of clinical pædiatry in the same seat of learning, to whom all communications by intending participants in the congress should be addressed.

The Opening of the Annus Academicus.

When after its long *siesta* academic life has re-awakened and all the schools are starting on another year of activity, it may interest the English-speaking world to know what part Italy is taking in the equipment of her professional classes. The last statistics available are those for 1906–07, from which we find that the great seats of learning continue to be thronged—the University of Naples above all. At the close of the last academic year the legal faculty enrolled 2263, while in all the rest of the kingdom—comprising the "free" Universities of Camerino, Ferrara, Perugia, and Urbino—the students of the same faculty barely reached 7161. The Universities of Cagliari, Ferrara, Perugia, and Siena numbered least. Again, in the faculty of medicine and surgery the Neapolitan school outsoars all her sisters, enrolling 1427 students. Immediately after Naples come Rome, Palermo, and Turin, then Bologna, Padua, and Genoa. The classes of physics, chemistry, and the natural sciences are the least frequented, just as the aspirants to graduation in engineering are more numerous than the aspirants to graduation in mathematics; the difference, however, in the total is very small, well-nigh incalculable, while as between one university and another it is considerable. In pharmacy the similar aspirants are not many, the University of Turin claiming the largest contingent—130—the candidates for the professional diploma, all told, being 2601. Philosophy and literature claim 152 students at Turin, but Naples and Rome make a better show, the former with 307, the latter with 226. Then come Bologna with 115, Padua with 80, and Pisa with 70. Very few are the notaries and solicitors—388 in all. Academically accredited midwives amount to 1370 Rome numbering only 98, as against the 235 of Naples, 172 of Padua, and 227 of Pavia. It will be seen that the professional classes draw more recruits in Southern Italy and fewer in Northern Italy, the explanation being that in the north the openings for the comparatively lucrative *métiers* of commerce and industry are more inviting as well as more numerous, the north, moreover, attracting fewer candidates for the poorly-paid offices under Government, communal, or municipal. Veterinary surgery and agriculture draw few to their class-rooms, the former counting only 346, the latter 273. For the whole Italian kingdom (mainland and islands) the University students all told amount to 24,038, besides the 1491 who attend the "Istituti di Studi Superiori" like that of Florence; or the "Accademia Scientifico-Letteraria" of Milan; the "Scuola di Applicazione" of Rome; the "Scuola Superiore Navale" of Genoa; or the "Scuola Superiore Politecnica" of Naples. The "University Schools" annexed to the Lycées of Aquila, Bari, and Catanzaro have 273 pupils and the superior institutions for the training of female teachers in Rome and Florence 293. In all, the student population in attendance at seats of learning throughout Italy for the academic year 1906–07 were 26,096, marking a considerable diminution on the numbers of previous "anni academici."

Sept. 14th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Small-pox in Vienna.

THE epidemic of small-pox mentioned in my last letter is not yet entirely checked although the number of fresh cases within the last fortnight has not been more than five or six daily. Altogether 130 cases have been notified and about 500 persons who had been in more or less close contact with the patients were removed for quarantine, but up to the present time only a few of them have shown symptoms of the disease. The recommendation of the sanitary authorities that everyone should be revaccinated has been well responded to and the ample opportunities offered by the public vaccination stations were freely made use of, so that from 25,000 to 30,000 persons were reported as having been vaccinated or revaccinated every day. In less than a month about 1,000,000 persons, or half the population of Vienna, had been vaccinated at these stations and the number of vaccinations performed by medical men in private practice is estimated at a quarter of a million, so that both the vaccinators and the establishments where lymph is produced were kept very busy. As yet the outbreak has been confined to two densely populated districts in the south-west of the city, but in order to prevent extension the opening of the schools has been postponed until Oct. 1st, by which time the disease will probably be under control. Although many of the cases have been of a mild type the mortality is already 10 per cent. of the persons attacked, 76 per cent. have either not been vaccinated at all or have not been revaccinated within the last 20 years, whilst the remainder came from the district where the disease was prevalent and had been infected before the protective influence of revaccination had time to be developed. Of the patients who succumbed none had ever been vaccinated. The age incidence was as follows: 66 per cent. of the patients were under 25 years of age, 25 per cent. were between 25 and 50 years, and the rest were above 50 years, the oldest being 58 years. 30 per cent. of all patients were children below five years of age, which shows well the necessity of early vaccination; the youngest child who was attacked was two months old and the case terminated fatally. The precautions taken were, and are, very extensive and are worth recording. All public institutions and theatres, all factories, workshops, general stores, drapery shops, banking houses, post offices, tramway companies, and railway companies had their employees vaccinated by specially appointed medical men, and the fact was notified in the newspapers so that the public might have no fear of infection from these quarters. Vaccination was, in fact, the only topic of the day. In spite of the mischievous endeavours of the "nature-cure" partisans to shake public confidence in the beneficial effect of vaccination, the attitude of the general population has been quite praiseworthy.

Old-age Pensions for Country Medical Men.

Some months ago a kind of strike movement was initiated among the country practitioners as a protest against the inadequate fees paid for public vaccination. This agitation has borne good fruit, for it has now been resolved by the Diet of Lower Austria that all district and country practitioners shall be entitled to a pension of about £65 a year after 30 years of service and that half of that sum shall be paid to their widows, besides certain fractions of that sum for each child. If a practitioner is

The writers had evidently failed to grasp the subject, for they attempted an important work without adequate expenditure and made other mistakes. Their reports were exhaustively criticised by Giles, Sewell, and myself,[36 37] but they nevertheless retarded Indian antimalarial efforts for some time.

Since then, to judge from accounts in the Indian sanitary reports[38] and from details very kindly furnished to me by Surgeon-General A. Scott Reid, I.M.S., and Colonel H. D. Rowan, R.A.M.C., wider measures have been attended with better results. Since 1905 the following measures have been adopted. The principal irrigation canal and its branches were closed within a radius of about 800 yards of the barracks and officers' quarters. The surface of the ground was everywhere levelled and the drainage improved so that even after a heavy fall of rain not a single collection of water will be found after 72 hours (except a large pit which is in course of being filled in). The whole cantonment was divided into six areas, each under a medical officer, and each area is visited once a week by a strong "mosquito brigade." All wells are protected and those used for irrigation purposes are oiled once a week. Quinine is administered twice a week on consecutive days from June to November under medical supervision. Residents are held strictly responsible for the condition of their compound (gardens). No undergrowth or rubbish is allowed, nor pits for the reception of sullage water; and other general sanitary improvements have been made.

In estimating the results Colonel Rowan remarks that the statistics of mortality in the civil population cannot be relied upon and that there are difficulties in connexion even with those of the troops. Since 1905 cases have been returned as malaria only when a microscopic diagnosis has been made and are otherwise given under the heading of simple continued fever (exclusive, of course, of typhoid or undulant fever); but he remarks that this is not quite fair amongst men who are getting quinine with such regularity. He thinks it best to take the admission-rates for malaria and simple continued fever together, and these show a considerable decline. For the five years 1898–1902, the average annual admission-rate per 1000 of the British (white) troops was about 900. In 1903 it was nearly 1100; but in 1904, 1905, and 1906 it fell to about 600, 400, and 460 respectively. The general admission-rates for all disease among these troops were 1950 in 1898–1902, 1800 in 1903, 1350 in 1904, 1350 in 1905, and 1240 in 1906. In a native cavalry regiment which has remained in Mian Mir for the whole of 1904, 1905, and 1906, the admission-rates for malaria per 1000 have been 242, 108, and 43 respectively. On the whole, he is satisfied with the success of the campaign, but thinks it too early to form an estimate of the full extent of the gains. I am told also that the fact that the troops have to serve frequently at Fort Lahore, a very unhealthy place, does much to distort the figures. But the measures are reported (18, p. 231) to "have undoubtedly contributed to the decreased prevalence of anopheline mosquitoes and their larvæ during the year." Colonel Rowan tells me that culex are much less common and that anophelines "have become positively rare," although a native is specially employed to find them if possible.

Progress of events.—In January, 1902, a conference of medical men on the subject of malaria was held at Nagpur. It drew up an excellent set of rules for antimalarial sanitation, but so far as I can gather no general orders were issued to make the rules compulsory. Gradually, however, several stations began to adopt measures on a small scale, chiefly, I think, owing to the initiative of individual medical officers, though the results at Mian Mir were frequently used to discourage them. Apart from practical work numerous good articles on mosquitoes and their habits appeared.[39 40] It is difficult to give any adequate account of the campaigns because the full facts are not obtainable, but I will refer briefly to the following.

Major W. J. Buchanan, I.M.S., Inspector-General of Prisons in Bengal, has been good enough to give me some details of his campaign at Buxor Central Jail. Buxor, in Bengal, is full of malaria, attributed to the large number of small irrigation canals. The jail is a good one, well situated and drained, but it has one irrigation canal entering it in order to supply water. In June, 1904, Major Buchanan had the canal banks close cut, cleared, and tarred, and gave similar treatment to certain tanks. All pools, puddles, and hollows were filled up and land in a neighbouring village was acquired for the purpose, while quinine was given every Saturday and Sunday during the malaria season. The results among the prisoners (averaging about 1400) were:—

Years...	1902	1903	1904	1905	1906
Admissions for malaria	2091	2455	1267	1207	1191

It should be remembered that prisoners are constantly being changed, new and infected criminals being frequently introduced from outside. Major Buchanan adds that he is adopting similar measures in all jails. It is difficult to find mosquito larvæ in any of the better situated ones. He approves of quinine prophylaxis in addition.

In the Madras Presidency Colonel W. G. King, I.M.S., the Sanitary Commissioner, early took interest in antimalaria work and commenced to organise mosquito brigades, and in 1904 the Government was reported to have taken active steps in this direction. It accepted Colonel King's scheme, suggested a suitable organisation, and advised municipal councils to meet the expenditure required.[39] I have not yet seen any description of the results.

Captain C. A. Sprawson, I.M.S., has been kind enough to give me many details of the work at Jhansi, a town of 12,457 inhabitants in Bundelkand. Operations appear to have been started at the beginning of the rains in 1906. The cantonment was divided into two areas, one for the white troops and one for the native troops, each division being placed under the appropriate medical officers under whom mosquito brigades were appointed. The native quarter was also looked after. Instruction regarding malaria was made public. The money allotted for the actual work, however, appears to have been rather small, as it was not allowed to exceed about £23 a year—less than a ½*d.* per head of population and 2*d.* per acre of land. As a matter of fact, the admission-rate for malaria seems to have increased rather than diminished, for it was 246·5 per cent. in 1906 against only 71·8 per cent. in 1905. The surrounding villages appear to have been left untreated and the cantonment itself is full of borrow-pits.

Although campaigns seem to have been at least commenced in many stations in India, I can gather only meagre and insufficient information about them in the official reports. At Jubbulpore and Dinapore considerable drainage and anti-mosquito works, combined with quinine prophylaxis, appear to have produced marked effects (38, p. 16). Active, and so far as I can ascertain (18, p. 230) enthusiastic, measures have been adopted in Peshawur, Rawal Pindi, Sialkot, Ferozepore, Karachi, Mhow, Kamptee, Deesa, and Saugor; and in Burma (41, p. 6), in Akyab, Myitkyina, Monywa, Paletwa, Mogok, Kyaukpyu, and Maymyo. At Mogok Captain J. Good, I.M.S., reports a diminution of malarial fevers (diagnosed by the microscope) from 25·4 per cent. of admissions in 1905 to 16·4 in 1906. As a rule, however, neither results nor expenses are given in the official reports.

The total amount of malarial fever in India, with its population of about 300,000,000, is immense. There must be several millions of deaths directly or indirectly due to it every year. Among the troops and prisoners in jails the annual number of admissions into hospital for malaria equal between a quarter and a half of the total strength. It is therefore very necessary that all the antimalarial work throughout the country should be dealt with in a business-like manner and that the results obtained should be collected and published for guidance and study.

VII.—OTHER CAMPAIGNS.

Khartoum.—This very interesting work was commenced in 1903 by Dr. Andrew Balfour, director of the Wellcome Research Laboratories of the Gordon Memorial College, and will be found accurately described in the two fine reports of the laboratories,[41] to which I must refer for details. After a preliminary survey of the local mosquitoes, a small brigade was started on the lines laid down by me and quickly attacked the breeding places. These in Khartoum were wells, pits, garden tanks and pools, sullage pits, river pools, and collections of water in steamers and barges. After heavy rain large pools which may last for some time form

[41] Balfour: First and Second Reports of the Wellcome Research Laboratories, 1904

All-India Hospital Assistants' Journal. The competition, which was restricted to assistant surgeons and hospital assistants, produced no fewer than 14 essays, of which the majority were highly praiseworthy. The author of the second best essay is first grade civil hospital assistant Annanda Charan Sarcar, who is in charge of the dispensary at Jugdispur in the Shahabad district. According to our contemporary this gentleman's essay is particularly valuable on account of the personal experience of the writer who gives a very satisfactory account of the methods which have been found successful in his district for destroying rats. Other essays worthy of mention, continues the editor, are those by (1) assistant surgeon Guru Prasad Mitra, M.B., of Dibrugar, Assam, which shows a very careful study of the most recent literature of plague; (2) assistant surgeon S. K. Vaidya of Mirpur Khas, Sind; (3) assistant surgeon Abdul Ghani of Bareilly; (4) hospital assistant Veeraswamy Raidu of Mandalay; (5) assistant surgeon S. C. Basu of Rawal Pindi; and (6) assistant surgeon U. Ray of Harda, United Provinces. The place of honour in the *Indian Medical Gazette* for August is accorded to Mr. Ramachandrier's prize essay, which is printed *in extenso*. In addition to adequate scientific equipment the writer possesses a thorough knowledge of the habits and customs of his native country and is, moreover, able to convey his meaning in clear and convincing if somewhat unconventional language. Mr. Ramachandrier's essay is a thoroughly practical document, well worthy of the attention of the authorities in India who are chiefly concerned in the repression of plague. His knowledge of the inner life of the people of India is invaluable, combined as it is with the will and the ability to place it at the disposal of the executive.

PUBLIC VACCINATORS' FEES.—Some time ago the Wandsworth board of guardians decided to adopt the minimum scale of fees for public vaccination. At the meeting of the board a month ago the practitioners affected sent a deputation and pointed out the inadequacy of the fee of 2*s*. 6*d*. for primary vaccination at a child's home. The guardians as a whole agreed and were willing to increase the amount to 3*s*. 6*d*., but a point of order was raised by an anti-vaccination member with the result that the subject had to be adjourned. At the meeting of the board held on Sept. 12th a letter was submitted from Mr. E. R. Badcock on behalf of the public vaccinators stating that they were prepared to accept the new fees with the exception of that for primary vaccination at the child's home. They suggested that 5*s*. should be paid as formerly in respect of every such vaccination, with a reduced fee of 2*s*. 6*d*. for the second and subsequent cases. A guardian raised a point of order—namely, that before the subject could be considered there must be a motion to rescind the resolution which adopted the reduced scale. This was conceded and the vice-chairman of the board gave notice of his intention at the next meeting to move the rescinding of the resolution referred to.—At a meeting of the Bodmin (Cornwall) board of guardians held last week a letter was read from the eight public vaccinators of the union stating that they were unable to accept the reduced scale of vaccination fees suggested by the guardians and adding that in the opinion of the writers the Order of the Local Government Board was evidently not intended to apply to such a scattered district as the Bodmin union. After some discussion the guardians referred the matter to the finance committee.

POST-GRADUATE WORK IN HAMBURG.—"D. J. G." writes to us as follows: "During a recent visit to the hospitals of Hamburg I have been much impressed not only by their excellent management but by the facilities they afford for post-graduate work. The general hospital at Eppendorf is a modern edifice built on the pavilion system and having accommodation for over 2000 patients. Its surgical department is under the care of Professor Kümmell, whose orthopædic work is well known, whilst Dr. Unna has charge of those wards reserved for cases of skin disease. There are many other pavilions, all of them airy, clean, and orderly; indeed, Hamburg may well be proud of this splendid hospital. Nearer the centre of the city, amid beautiful grounds, stands the Hospital of St George, containing about 1000 beds. There is here a large and well-equipped pathological laboratory in which each of the assistant physicians and surgeons has his bench for research work. Post-graduate courses, each lasting for several weeks, are held yearly at those hospitals. The Eppendorf course is held in August and that at the St. George during March. One may then attend medical and surgical cliniques and receive practical instruction in ophthalmology, gynæcology, laryngoscopy, medical electricity, &c. Those who take advantage of the classes are for the most part German practitioners, and remarkably few English names are to be seen in the visitors' books of the hospitals. A course of a practical nature on tropical diseases is given twice a year at the Hamburg Seamen's Hospital and here also ship surgeons may be taught their special duties. To the doctor who has little time at his disposal but who wishes to see something of German methods and work one can have no hesitation in recommending Hamburg as a place of study."

SEAMEN'S HOSPITAL SOCIETY.—The inaugural address of the winter session of the London School of Clinical Medicine will be delivered in one of the lecture rooms of the school by Sir Richard Douglas Powell, President of the Royal College of Physicians of London, on Tuesday, Oct. 8th. The chair will be taken at 3.30 P.M. by Mr. Perceval A. Nairne, chairman of the board of governors. The school and hospital will be open for inspection and tea will be served after the address.

GREAT NORTHERN CENTRAL HOSPITAL: A CORRECTION.—The secretary of this hospital writes to inform us that the names of the staff of the hospital, as sent to us from the institution and published in the Students' Number of THE LANCET, are not given quite accurately. The staff is as follows:—Consulting Physicians: Sir S. Wilks, Bart., and Dr. R. Burnet. Physicians: Dr. E. C. Beale, Dr. C. E. Beevor, Dr. A. Morison, Dr. T. J. Horder, Dr. H. E. Symes-Thompson, and Dr. H. W. Willcox. Obstetric Physicians: Dr. G. F. Blacker and Dr. Cuthbert Lockyer. Physician for Skin: Dr. A. Whitfield. Surgeons: Mr. P. T. B. Beale, Mr. G. B. M. White, Mr. E. C. Stabb, Mr. V. W. Low, and Mr. Arthur Edmunds. Ophthalmic Surgeons: Mr. A. S. Morton and Mr. George Coats. Throat and Ear Surgeons: Mr. E. B Waggett and Mr. J. Gay French. Dental Surgeon: Mr. C. Peyton Baly.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At Wadebridge (Cornwall) on August 30th Mr. William Annesley Eden, L.R C P. Lond., M.R.C S Eng., L.S.A., was presented with a silver rose bowl as a mark of respect and esteem on the occasion of his leaving the town.—At the meeting of the Long Ashton (Somerset) board of guardians held on Sept. 3rd, under the presidency of Sir Henry Miles, Mr. Frederick Weatherly, M.R C.S. Eng., L.S A., J.P., was presented with a silver tray, tea and coffee services, and kettle. On the back of the tray was the following inscription: "This tray, with tea and coffee services and kettle, was presented to Frederick Weatherly, Esq., J.P., in his eighty-eighth year, by past and present guardians of the Long Ashton Union and other friends, as a mark of their esteem and appreciation of his public services as vice-chairman and chairman of the board for a period extending over a quarter of a century."—Mr. Elearar Davies, L.R.C P. & S. Edin., and Mrs. Davies have been presented by the inhabitants of Pantywaun, near Dowlais, with a silver tray (suitably inscribed), silver cruet, and a work-basket.

THE FUNERAL OF MR. TIMOTHY HOLMES.—Mr. Timothy Holmes, senior consulting surgeon to St George's Hospital, who died on Sunday, Sept. 8th, was buried on the following Thursday at Hendon. Among those who attended the funeral, in addition to members of the families of Mrs. Holmes and of the deceased, were Sir William S. Church, representing the Royal Society of Medicine, Mr. Holmes having been formerly President of the Royal Medical and Chirurgical Society; Mr. J. Warrington Haward, representing the Royal College of Surgeons of England, of which Mr. Holmes was formerly Vice-President; Sir Alexander Bruce, Sir Melville Macnaghten, and Mr. Clinton T. Dent, representing Scotland Yard, Mr Holmes having for 20 years been chief surgeon to the Metropolitan Police; Lieutenant-Colonel Montefiore, representing the Charity Organisation Society; the Rev. A. G. Locke, representing the governors of St. George's Hospital; Mr Herbert S Pendlebury, honorary treasurer of that hospital; Mr. M. P. Jasper, representing the London Sanitary Protection Association, of which body Mr. Holmes was chairman; Dr. G. F. Blandford, Dr. Frederic W. Hewitt, Mr. W. C. Bull, and possession of the works early in 1904, at a time when the mode of propagation and of prevention of both diseases was well known, and they wisely determined to commence their labours with sanitation. Colonel Gorgas, assisted by a capable and enthusiastic staff, was put in charge and attacked the work with knowledge and energy. I visited the place at his invitation in the autumn of 1904 and was a witness of the skill shown in his dispositions. The country is one of the worst to deal with which I have ever seen. Hilly, with a great rainfall, a loose crumbling soil, a luxuriant vegetation, and innumerable small marshes and pools, it was evidently the very stronghold of malaria. Step by step, with the aid of numerous experts and hundreds of workmen, the Americans cleared the forests, drained the pools, and banished the stegomyia. The details and the results will be found in the monthly and annual reports of the work[49] and in a recent address by Colonel Gorgas.[50] Put briefly, the results are that in 1906 amongst 5000 white American employees the total death-rate was only 7 per mille, and of this only 3·8 per mille were due to disease. Last April the daily sick-rate of the total force of about 40,000 people was only 17 per mille. Colonel Gorgas says: "Among 6000 Americans in the employ of the Commission, including some 1200 American women and children, the families of these employees, we have but little sickness of any kind, and their general appearance is fully as vigorous and robust as that of the same number of people in the United States." These published statements are fully borne out by private communications from individuals living there. Colonel Gorgas adds: "I think the sanitarian can now show that any population coming into the tropics can protect itself against these two diseases (yellow fever and malaria) by measures that are both simple and inexpensive ......; and that again the centres of wealth, civilisation, and population will be in the tropics as they were in the dawn of man's history. ......"

In this great work of Colonel Gorgas and his colleagues I recognise the attainment of that ideal which was set before me when, ten years ago, I found the zygotes of the parasites of malaria in mosquitoes. I regret only that the honour of attaining it has not fallen to my countrymen, as might well have been the case. But we must none the less congratulate the Americans on the splendid achievement with which they have signalised their entry into the lists of the colonising nations of the world.

IX.—REMARKS AND CONCLUSIONS.

Exigencies of space have compelled me to be very brief in my descriptions of the above campaigns. In addition to them good work has been commenced in the Andaman Islands, Ceylon, South Africa, Southern Rhodesia, British Central Africa, Sapele (West Africa), and Mauritius (which last-named place I hope to visit shortly on behalf of the British Government). Good work has also been done in connexion with many mines and railways in West Africa; but at present details regarding most of these campaigns are not available, or are either too meagre or buried in inaccessible local reports. The excellent antimosquito work of Doty and of Weeks and others in the United States, and of the French in Corsica and Algeria, is somewhat outside my province. I should have liked to describe the operations in Greece (which I was able to visit last year), but this will be done much better by my distinguished friend Professor Dr. Savas. For many papers on the prevention of malaria I must refer to the British medical press, especially THE LANCET, the British Medical Journal, the Indian Medical Gazette, and the Journal of Tropical Medicine.

From all the experiences collected and the discussions carried on during these ten years the following general conclusions are now, I think, beginning to emerge:—

1. For tropical sanitation against both malaria and yellow fever (and probably filariasis) general mosquito reduction is by far the most practical, as it is the most fundamental, method, at least in thickly populated areas. In support of this proposition, originally advanced by Finlay for yellow fever and now by myself for malaria, it suffices to quote the greatest living authority on the prevention of both these diseases—Colonel Gorgas—who for more than six years continuously has been waging successful war against them, not on a small but on a large scale, and not in easy but in the most difficult possible conditions. Regarding yellow fever, he says[50]: "When we left Cuba after the disappearance of yellow fever, we were inclined to think that the results had been obtained principally by the destruction of the infected stegomyia, but further experience at Panama has convinced me that the important element is the destruction of stegomyia generally. I merely mention this as showing how practical work and experience entirely change well-grounded theories." Regarding malaria, after enumerating the various methods of prevention, he says[50]: "By far the most important of these measures is that of destroying the breeding places and this is successfully done by surface and subsoil drainage." So many people write on this subject without any real practical experience of it that we shall do well in future if we listen more attentively to such words as these of Colonel Gorgas.

2. Prophylaxis by quinine, by screens, and by segregation may be attempted, if possible, in addition to the fundamental measure, but, as regards tropical towns, must be looked upon only as adjuvants to it. As a rule, in the tropics general cinchonisation is feasible only for officials, troops, and bodies of workmen; and screening and segregation can seldom be used except for public buildings and the houses of Europeans. All should be advocated, but there is a distinct danger of wasting on the subsidiary measures efforts and funds which might be more usefully spent on the fundamental one, a thing which I have frequently observed to happen. For example, cinchonisation is being much advocated, and quite rightly so, for the troops in India; but at the same time irrigated fields are often permitted to remain in the close vicinity of barracks. Hence, while the number of relapses among the men may be reduced, yet probably just as many as before become infected from the surrounding untreated population and a false impression of improvement is given. It is constantly forgotten that for the individual quinine is, properly speaking, not a prophylactic at all—it does not exclude infection, but merely extirpates it (in some cases) after it has effected an entry. It is poor policy to substitute a possible extirpation for a certain exclusion. On the other hand, the subsidiary measures become essential where it is not worth while to attempt mosquito reduction, as in the case of camps and of many isolated houses, farms, plantations, &c.

3. There is no doubt that the mere knowledge of the fact that mosquitoes cause infection is producing a great improvement of the health of educated people in the tropics. This occurs in two ways: first, such people are more careful in the use of nets; and, secondly, medical men, without undertaking formal campaigns, do more than formerly to suppress breeding pools close to houses, barracks, &c. There is thus a kind of unconscious prophylaxis beginning to be adopted everywhere. The following figures, which I have collected from the Indian Sanitary Reports[39] give some evidence of this:—

Admission Rates per 1000 for Malaria in India.

Years . .	1896	1897	1898	1899	1900	1901	1902	1903	1904	1905
Jail prisoners	292	383	348	350	364	382	375	366	346	336
Native troops	292	363	355	277	335	373	288	256	201	180
White troops	253	420	427	245	321	300	254	247	177	114.

These statistics refer to the prisoners and troops of the whole of India, and are, therefore, very reliable. It will be observed that the admissions among the prisoners have not decreased, owing to the fact that these people, drawn from the lowest classes of the population, are constantly being changed in the jails, so that sanitary improvements as regards malaria in these buildings can produce little effect on their fluctuating population. On the other hand, there appears to be a considerable decrease among the troops, all of whom have medical men in charge of them, while the white troops are provided also with mosquito nets or punkas. There has been a slight increase in the amount of simple continued fever diagnosed, but not nearly enough to account for the fall in the malaria rate.

4. But unconscious prophylaxis of this kind will not do everything, and State intervention is necessary if the fullest results are to be obtained. Here two great mistakes have been made.

The first mistake is to suppose that we can educate the general public by means of notices and pamphlets to protect themselves against disease— mistake constantly made by inexperienced sanitarians. people in this way, but, as knows, the masses will not tro

[49] Reports of the Department of Health of the Isthmian Canal Commission, Monthly and Annual. Government Printing Office, Washington.

[50] Gorgas: Sanitation in the Canal Zone, Journal of the American Medical Association, July 6th, 1907.

All-India Hospital Assistants' Journal. The competition, which was restricted to assistant surgeons and hospital assistants, produced no fewer than 14 essays, of which the majority were highly praiseworthy. The author of the second best essay is first grade civil hospital assistant Annanda Charan Sarcar, who is in charge of the dispensary at Jugdispur in the Shahabad district. According to our contemporary this gentleman's essay is particularly valuable on account of the personal experience of the writer who gives a very satisfactory account of the methods which have been found successful in his district for destroying rats. Other essays worthy of mention, continues the editor, are those by (1) assistant surgeon Guru Prasad Mitra, M.B., of Dibrugar, Assam, which shows a very careful study of the most recent literature of plague; (2) assistant surgeon S. K. Vaidya of Mirpur Khas, Sind; (3) assistant surgeon Abdul Ghani of Bareilly; (4) hospital assistant Veeraswamy Raidu of Mandalay; (5) assistant surgeon S. O. Basu of Rawal Pindi; and (6) assistant surgeon U. Ray of Harda, United Provinces. The place of honour in the *Indian Medical Gazette* for August is accorded to Mr. Ramachandrier's prize essay, which is printed *in extenso*. In addition to adequate scientific equipment the writer possesses a thorough knowledge of the habits and customs of his native country and is, moreover, able to convey his meaning in clear and convincing if somewhat unconventional language. Mr. Ramachandrier's essay is a thoroughly practical document, well worthy of the attention of the authorities in India who are chiefly concerned in the repression of plague. His knowledge of the inner life of the people of India is invaluable, combined as it is with the will and the ability to place it at the disposal of the executive.

PUBLIC VACCINATORS' FEES.—Some time ago the Wandsworth board of guardians decided to adopt the minimum scale of fees for public vaccination. At the meeting of the board a month ago the practitioners affected sent a deputation and pointed out the inadequacy of the fee of 2s. 6d. for primary vaccination at a child's home. The guardians as a whole agreed and were willing to increase the amount to 3s 6d., but a point of order was raised by an anti-vaccination member with the result that the subject had to be adjourned. At the meeting of the board held on Sept. 12th a letter was submitted from Mr. E. R. Badcock on behalf of the public vaccinators stating that they were prepared to accept the new fees with the exception of that for primary vaccination at the child's home. They suggested that 5s. should be paid as formerly in respect of every such vaccination, with a reduced fee of 2s. 6d. for the second and subsequent cases. A guardian raised a point of order—*namely*, that before the subject could be considered there must be a motion to rescind the resolution which adopted the reduced scale. This was conceded and the vice-chairman of the board gave notice of his intention at the next meeting to move the rescinding of the resolution referred to.—At a meeting of the Bodmin (Cornwall) board of guardians held last week a letter was read from the eight public vaccinators of the union stating that they were unable to accept the reduced scale of vaccination fees suggested by the guardians and adding that in the opinion of the writers the Order of the Local Government Board was evidently not intended to apply to such a scattered district as the Bodmin union. After some discussion the guardians referred the matter to the finance committee.

POST-GRADUATE WORK IN HAMBURG.—"D. J. G." writes to us as follows: "During a recent visit to the hospitals of Hamburg I have been much impressed not only by their excellent management but by the facilities they afford for post-graduate work. The general hospital at Eppendorf is a modern edifice built on the pavilion system and having accommodation for over 2000 patients. Its surgical department is under the care of Professor Kümmell, whose orthopædic work is well known, whilst Dr. Unna has charge of those wards reserved for cases of skin disease. There are many other pavilions, all of them airy, clean, and orderly; indeed, Hamburg may well be proud of this splendid hospital. Nearer the centre of the city, amid beautiful grounds, stands the Hospital of St George, containing about 1000 beds. There is here a large and well-equipped pathological laboratory in which each of the assistant physicians and surgeons has his bench for research work. Post-graduate courses, each lasting for several weeks, are held yearly at those hospitals. The Eppendorf course is held in August and that at the St. George during March. One may then attend medical and surgical cliniques and receive practical instruction in ophthalmology, gynæcology, laryngoscopy, medical electricity, &c. Those who take advantage of the classes are for the most part German practitioners, and remarkably few English names are to be seen in the visitors' books of the hospitals. A course of a practical nature on tropical diseases is given twice a year at the Hamburg Seamen's Hospital and here also ship surgeons may be taught their special duties. To the doctor who has little time at his disposal but who wishes to see something of German methods and work one can have no hesitation in recommending Hamburg as a place of study."

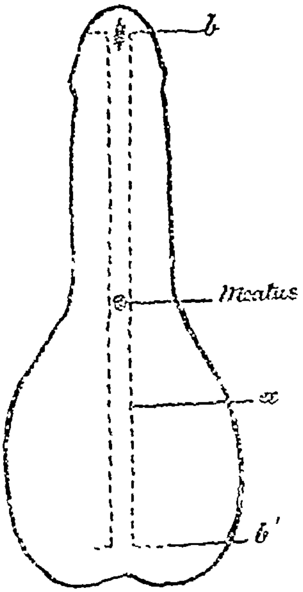
SEAMEN'S HOSPITAL SOCIETY.—The inaugural address of the winter session of the London School of Clinical Medicine will be delivered in one of the lecture rooms of the school by Sir Richard Douglas Powell, President of the Royal College of Physicians of London, on Tuesday, Oct. 8th. The chair will be taken at 3.30 P.M. by Mr. Perceval A. Nairne, chairman of the board of governors. The school and hospital will be open for inspection and tea will be served after the address.

GREAT NORTHERN CENTRAL HOSPITAL: A CORRECTION.—The secretary of this hospital writes to inform us that the names of the staff of the hospital, as sent to us from the institution and published in the Students' Number of THE LANCET, are not given quite accurately. The staff is as follows:—Consulting Physicians: Sir S. Wilks, Bart., and Dr. R. Burnet. Physicians: Dr. E. O. Beale, Dr. O. E. Beevor, Dr. A. Morison, Dr. T. J. Horder, Dr. H. E. Symes-Thompson, and Dr. H. W. Willcox. Obstetric Physicians: Dr. G. F. Blacker and Dr. Cuthbert Lockyer. Physician for Skin: Dr. A. Whitfield. Surgeons: Mr. P. T. B. Beale, Mr. G. B. M. White, Mr. E. C. Stabb, Mr. V. W. Low, and Mr. Arthur Edmunds. Ophthalmic Surgeons: Mr. A. S. Morton and Mr. George Coats. Throat and Ear Surgeons: Mr. E. B Waggett and Mr. J. Gay French. Dental Surgeon: Mr. C. Peyton Baly.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At Wadebridge (Cornwall) on August 30th Mr. William Annesley Eden, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., was presented with a silver rose bowl as a mark of respect and esteem on the occasion of his leaving the town.—At the meeting of the Long Ashton (Somerset) board of guardians held on Sept. 3rd, under the presidency of Sir Henry Miles, Mr. Frederick Weatherly, M.R.C.S. Eng., L.S.A., J.P., was presented with a silver tray, tea and coffee services, and kettle. On the back of the tray was the following inscription: "*This tray, with tea and coffee services and kettle, was presented to Frederick Weatherly, Esq., J.P., in his eighty-eighth year, by past and present guardians of the Long Ashton Union and other friends, as a mark of their esteem and appreciation of his public services as vice-chairman and chairman of the board for a period extending over a quarter of a century.*"—Mr. Eleazar Davies, L.R.C.P. & S. Edin., and Mrs. Davies have been presented by the inhabitants of Pantywaun, near Dowlais, with a silver tray (suitably inscribed), silver cruet, and a work-basket.

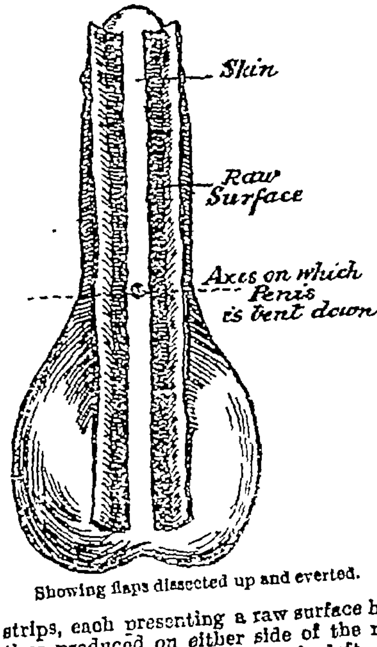
THE FUNERAL OF MR. TIMOTHY HOLMES.—Mr. Timothy Holmes, senior consulting surgeon to St George's Hospital, who died on Sunday, Sept. 8th, was buried on the following Thursday at Hendon. Among those who attended the funeral, in addition to members of the families of Mrs. Holmes and of the deceased, were Sir William S. Church, representing the Royal Society of Medicine, Mr. Holmes having been formerly President of the Royal Medical and Chirurgical Society; Mr. J. Warrington Haward, representing the Royal College of Surgeons of England, of which Mr. Holmes was formerly Vice-President; Sir Alexander Bruce, Sir Melville Macnaghten, and Mr. Clinton T. Dent, representing Scotland Yard, Mr Holmes having for 20 years been chief surgeon to the Metropolitan Police; Lieutenant-Colonel Montefiore, representing the Charity Organisation Society; the Rev. A. G. Locke, representing the governors of St. George's Hospital; Mr Herbert S Pendlebury, honorary treasurer of that hospital; Mr. M. P. Jasper, representing the London Sanitary Protection Association, of which body Mr. Holmes was chairman; Dr. G. F. Blandford, Dr. Frederic W. Hewitt, Mr. W. C. Bull, and scrotal raphé and parallel to it until the incisions on the scrotum measured from the level of the misplaced meatus are equal in length to those on the penis measured from the same point to the point of their commencement on the glans penis. When these incisions are completed a median strip of skin a quarter of an inch in width is mapped out, reaching along the upturned ventral surface of the penis and the front of the scrotum, with the misplaced meatus at its centre. From the extremities of the two incisions bounding this strip of skin others are now made outwards at right angles, each a quarter of an inch in length (Fig. 1 *b b'*). In this way two longitudinal flaps are marked out on either side of the median strip of skin throughout its whole length. These flaps are dissected up off the sides of the penis and front of the scrotum respectively, and rolled outwards away from the middle line throughout their whole length (Fig. 2).

FIG. 1.



Showing incisions (dotted lines).

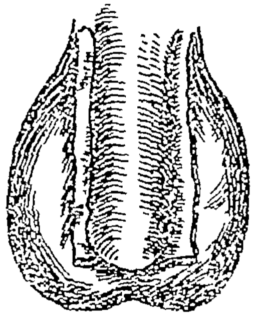
FIG. 2



Showing flaps dissected up and everted.

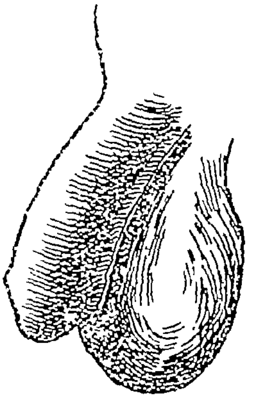
Two long strips, each presenting a raw surface half an inch wide, are thus produced on either side of the median strip of skin previously referred to, which is left undisturbed (Fig. 2). The flaps are held in the everted position with forceps throughout their whole length, and while in this position the penis is flexed down on to the scrotum in the middle line about a transverse axis passing through the misplaced urinary meatus (Fig 3). The median strip of skin on the ventral aspect of the penis and the raw areas flanking it thus come to lie on the corresponding median strip and raw surfaces on the front of the scrotum. The penile strip of skin will form a roof for the new urethra and the scrotal strip will form its floor. The raw surfaces on each side, when properly sutured, will cohere and grow together, fixing the penis to the scrotum and closing in the lateral aspects of the new urethral tube so as to render it watertight. The parts now present the following appearance. The penis lies on the front of the scrotum in the middle line like a complete web penis and on either side where they come together the opposed penile and scrotal flaps project so as to form a flange about a quarter of an inch in width, which extends from the root to the tip of the penis (Figs. 3 and 4).

FIG. 3.



Penis flexed on to scrotum with flaps everted.

FIG 4.



Side view of penis, flaps, and scrotum.

The penile and scrotal flaps forming each lateral flange are now sutured together in a special way. Each flange is transfixed by the needle, close to its free edge, and the needle is then reversed and passed through the flaps forming the flange in the opposite direction quite close to the attached borders of the flaps composing it. In this way a series of sutures are inserted at intervals of a quarter of an inch from the root of the penis to its tip, each running transversely to the axis of the penis, across the skin surfaces of the penile and scrotal flaps (Figs. 5 and 6). In passing each suture through the attached base of the flap special care is taken that the needle almost, but not quite, takes up the edges of the strips of attached skin, which will form the roof and floor of the new urethra, for it is important to approximate the epithelial margins without the suture projecting into the new urethral lumen (Fig. 6). All the sutures are passed before any are tied and before tying them two special manœuvres are carried out: (1) small rubber tubes are passed under the sutures on the front and back of each flange to avoid puckering of the skin and to keep up pressure over a broad area between the opposed raw surfaces of the flaps (Figs. 5 and 6); and (2) a small rubber catheter, with the eye cut off is passed along the track which will form the new urethra and pushed a short way down the previously formed urethra so as to drain off the urine without soiling the newly constructed portion. A suture at

Hospital for Women, Soho-square, W.—Resident Medical Officer for six months. Salary at rate of £60 per annum.

Infants' Hospital, Vincent-square, Westminster.—Honorary Medical Officer to the Nursing Staff.

Jersey Dispensary.—Resident Medical Officer. Salary £120, with furnished quarters and attendance.

Leicester Infirmary.—House Physician. Salary £100 per annum, with board, lodging, and washing.

Liverpool Eye and Ear Infirmary, Myrtle-street.—House Surgeon. Salary £80 per annum.

London Hospital, Whitechapel, E.—Surgeon Dentist.

Maidstone, Kent County Asylum.—Fourth Assistant Medical Officer, unmarried. Salary £175 per annum, with quarters, attendance, &c.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—Honorary Surgeon.

Manchester Royal Infirmary.—Resident Surgical Officer, unmarried. Salary £150 per annum, with board and residence.

Manchester, University of.—Senior Demonstrator in Physiology. Salary £150, rising to £200 per annum.

Newcastle-upon-Tyne, University of Durham College of Medicine.—Demonstrator of Physiology. Salary £200 per annum.

Norwich City Asylum, Hellesdon-next-Norwich.—Resident Medical Superintendent. Salary £400 per annum, rising to £600, with furnished residence, fuel, light, rates, washing, &c.

Paisley, Riccartsbar Asylum.—Assistant Resident Medical Officer. Salary £120 per annum, with board and apartments.

Plymouth, South Devon and East Cornwall Hospital.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, and washing.

Prince of Wales's General Hospital, Tottenham, London, N.—House Surgeon and House Physician. Salaries £75 per annum each. Also Junior House Surgeon and Junior House Physician. Salaries £40 per annum each. With residence, board, and laundry in each case; all for six months.

Reading, Royal Berkshire Hospital.—Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, lodging, and washing.

Royal Dental Hospital, Leicester-square.—Morning House Anæsthetist. Honorarium £50 per annum.

Royal London Ophthalmic Hospital, City-road, E.C.—Senior House Surgeon. Salary at rate of £100 a year, with board and residence.

Royal National Orthopædic Hospital, W.—Honorary Dental Surgeon. Also Honorary Assistant Anæsthetist.

St. Marylebone, Metropolitan Borough of.—Medical Officer of Health. Salary £700 per annum.

Salford Royal Hospital.—Junior House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Clinical Assistants.

Seamen's Hospital Society, Greenwich, S.E.—For Dreadnought Hospital: Two House Physicians and Two House Surgeons for six months. Salary at rate of £50 per annum, with board, residence, and washing. For Branch Hospital, Royal Albert Dock, E.: *Senior House* Surgeon for six months. Salary at rate of £75 per annum and additional £25 per annum for acting as Registrar, &c., with board, residence, and washing. Also House Surgeon for six months. Salary at rate of £50 per annum, with board, residence, and washing.

Settlement of Women Workers, Canning Town Medical Mission Hospital.—Honorary Anæsthetist (female).

Sheffield Royal Hospital.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

Sheffield Union Hospital.—Locum Tenens.

Taunton, Taunton and Somerset Hospital.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, *lodging*, and laundry.

Tunbridge Wells, General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance.

West London Hospital, Hammersmith-road, W.—Assistant Physician.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—House Surgeon for six months. Salary £30, with board and lodging.

Worcester County and City Asylum.—Third Assistant Medical Officer, unmarried. Salary £140, rising to £160, and all found.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as *Certifying Surgeons* under the Factory and Workshop Act at Newcastleton, in the county of Roxburgh, and at Rothwell, in the county of Northampton.

Births, Marriages, and Deaths.

BIRTHS.

Lloyd.—On Sept. 10th, at Park-street West, Luton, Beds., the wife of Francis Seymour Lloyd, M.D. Lond., of a daughter.

Niblock.—On Sept. 12th, at Orton Rigg, Canford Cliffs, Bournemouth, the wife of Major W. J. Niblock, I.M.S., of a son.

McElwee.—On Sept. 13th, at Belsize-avenue, London, N.W., the wife of Fleet-Surgeon John McElwee, Royal Navy, of a son.

MARRIAGE.

Williams—Freeman.—On Sept. 11th, at St. Stephen's Church, Lindley, Huddersfield, Alfred Williams, M.D., M.R.C.S., to Kathleen, elder daughter of Colonel and Mrs. C. R. Freeman of Oakwood, Edgerton, Huddersfield.

DEATH.

Crowfoot.—On Sept. 11th, at Beccles, Suffolk, William Bayly Crowfoot, M.A., M.B., B.C. Cantab., aged 29 years, from appendicitis.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PULVERMACHER INSTITUTE.

In the *Daily News* of Thursday, Sept. 12th, appears an editorial paragraph or an advertisement—there is nothing to show which—dealing with the Pulvermacher Institute. It is written, as is usual with puffs of quack appliances, in confidential, sympathetic style and gives a lurid picture of mental depression. After the reader has been brought to a properly anxious and miserable frame of mind he is incidentally told that if any reader of the *Daily News* feels interested in the matter a letter addressed to the superintendent of the Pulvermacher Institute will bring a book by return, and so forth. Now all this is part and parcel of the modern quack system, but what we do object to is the final paragraph which says that "it"—i.e., the Pulvermacher treatment—"is recommended by the highest Medical Hygienic Authorities, including, among many others, Sir Chas. Locock, Physician to our (*sic*) Majesty, and 'The Lancet,' the leading medical journal." This statement we have no hesitation in saying a deliberate lie inserted with the intent to deceive the public, and it is one of the worst kind of lies in that there is a modicum of truth therein. It is quite true that in the year 1856 we commented favourably upon the modification of the old-fashioned voltaic pile which was invented by Dr. Pulvermacher of Vienna, and it is quite possible that Sir Charles Locock, who has been dead upwards of 30 years, also expressed himself as favourably impressed with it, but the Pulvermacher Institute as at present constituted is simply a quack establishment presided over by a manager who, in December, 1906, was absolutely ignorant of any facts about electricity or its medical application. We interviewed this person at that date and an account of our interview with him will be found in The Lancet of Dec. 8th of that year. We showed that the institute was a purely quack establishment which exploited electricity and the writings of well-known authorities on medical electricity with a view to gulling the public and posing as being able to cure real or imaginary sexual and other disorders. We again charge the Pulvermacher Institute with deliberately making a false use of our name with the intent to deceive the public, and at the same time we may point out to the proprietors of the *Daily News* that by inserting this advertisement or editorial paragraph, whichever it may be, they are in any case assisting to deceive their fellow creatures and, if the paragraph should be a paid advertisement, they are profiting in pocket by the deception.

SPITTING.

To the Editors of The Lancet.

Sirs,—Although the by-law prohibiting people from spitting in public places, under a penalty of 40*s.* and costs for each offence, was issued by the London County Council as far back as July, 1903, only one delinquent, to my knowledge, has been convicted and fined, and even he would no doubt have escaped punishment had he not aggravated the situation by the use of obscene language. In my opinion, it is nothing short of scandalous that those who persistently and defiantly indulge in the filthy, disgusting, and, above all, *dangerous* habit of spitting in public buildings, carriages, &c., should go unpunished, and their perfect immunity from interference by the London County Council themselves, railway officials, and the like, only shows what an utter farce the by-law against spitting actually is. I have repeatedly communicated direct with the London County Council on this important matter, and even *gone so* far as to offer them my services in getting notices affixed where they are needed, and to otherwise assist them in suppressing this abominable public nuisance, but have received no support or encouragement whatever. I have also made suggestions to railway and omnibus companies in connexion with this subject, but they have done nothing beyond acknowledging my letters, nor do they seem to care one iota whether *the floors of their vehicles* are covered with expectorations or not, and this despite the fact that the by-law against spitting is included in their schedules. If an important statute—such as the one in question—is drawn up for the general good of the community and in the interests of the public health, it should be enforced with callous austerity, otherwise its enactment amounts to nothing more than a mockery and can only bring ridicule and contempt upon those who are responsible for it.

I am, Sirs, yours faithfully,

Oscar Mouat Balthasar.

South Hampstead, N.W., Sept. 11th, 1907.

"ELASTES" FOR AUTOCARS.

To the Editors of The Lancet.

Sirs,—Probably some of the readers of The Lancet who use autocars will be interested to hear my experience of "Elastes" filling for tyres. So far it is favourable. As regards comfort and freedom from vibration "Elastes" equals air as a filling for tyres. It entirely does away with the various troubles and delays incidental to pneumatics as ordinarily used. No change in wheels or rims is necessary, but the "Elastes" Co.

in ordinary circumstances 2. If the operation is done early may not the character of the epithelium be altered by environment and hair fail to develop? 3. Would the growth of hairs lead to trouble: as in cases where *the skin of the pubes is utilised to form the front of the* bladder in extroversion? In the first place, operations for extroversion are done at a later age when the hair has started to grow; secondly, the growth of hair is more exuberant here than on the scrotum; and thirdly, the great trouble caused by the hair in extroversion is due to alkaline decomposition and phosphatic deposit, due to the ill-formed bladder leaking and becoming infected. In a properly repaired urethra no such leakage would occur and alkaline decomposition would, I venture to believe, be unlikely to arise.

Devonshire-street, W.

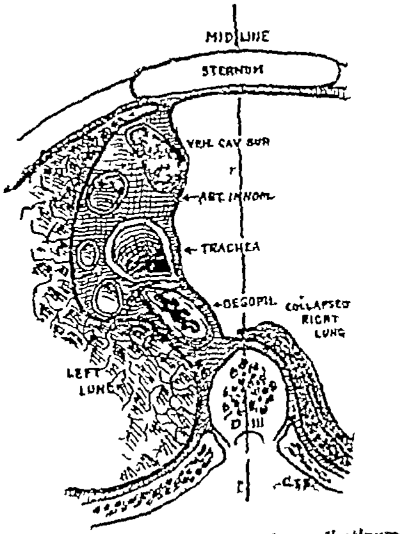
ON THE DISPLACEMENTS PRODUCED BY PLEURAL EFFUSION.

BY G. ELLIOT SMITH, M.A. CANTAB., M.D., CH.M. SYD., F.R.S.,
PROFESSOR OF ANATOMY, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE, CAIRO.

IN this communication I propose to describe the alterations in the topographical relations of the thoracic and abdominal viscera that may be produced by the effusion of fluid into the pleural sac. This is merely one part of a comprehensive study of the displacements of viscera that occur under physiological and pathological conditions which has engaged my attention for some time past. The discussion of the significance of "Grocco's triangle" which has appeared in recent numbers of THE LANCET has induced me to send these notes on the effects of pleural effusion as a contribution to the argument. I do not pretend to discuss the main points raised in the ingenious explanation of the physical signs of pleural effusion offered by Dr. F. W. Forbes Ross in THE LANCET of June 29th last, p. 1773, but the accurate record of the actual state of affairs in extreme cases of pleural distension cannot fail to be of value in such a discussion. As a rule physicians can form a mental picture of the topographical anatomy of the body cavity under pathological conditions only by inference from the physical signs, and anatomists are apt to draw conclusions as to what may happen when disease attacks the body merely from a study of the normal structure. In these notes I propose to describe what *actually* has happened in cases of pleurisy, when the patients have died untreated and the parts have been preserved and fixed in the positions which they occupied in life. Such an investigation has been rendered practically feasible only by the possession of such a fixative as formalin and by the opportunity of examining material which, in most countries, is available for such purposes only on the rarest occasions. In Egypt it is quite common for patients to pursue their ordinary occupations even when subject to the most serious diseases. Such patients are frequently brought into hospital in a moribund state after having been found in a helpless condition by the police and the unclaimed corpses of many of these people often find their way into the dissecting room. These frequent opportunities for studying the effects of disease on the anatomy of the body have been of the utmost value in teaching applied anatomy and many of the facts brought to light in conducting these classes seem to be of sufficient importance to impart to a larger audience. It will conduce to lucidity of exposition if, instead of describing what happens in a series of cases, I give a concise account of the condition found in one case of extreme distension of the right chest. From this it is easy to infer what happens in less advanced cases or in a lesion of the left side.

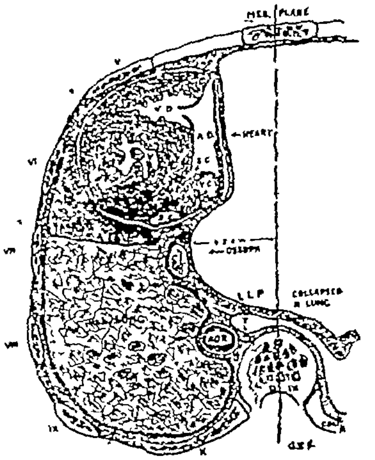
The patient was an adult Egyptian peasant who was brought to the Kasr-el-Ainy Hospital in a moribund condition and died without any treatment. My colleague, Professor A. R. Ferguson, has examined my specimens and tells me that this is a case of simple pleurisy with serous (non-purulent) effusion. The body was preserved within six hours after death (in mid-winter) by intravascular injection of 10 per cent. formalin. This fixed all the organs and tissues *in situ* and firmly coagulated the pleural fluid. The left pleura was almost universally adherent to the lung, which was healthy except for the presence of one very small caseous patch. The right lung was completely collapsed (Figs. 1 and 2) and was lying on the right side of the bodies of the vertebræ (from the third dorsal to the ninth dorsal inclusive). It extended so low only because an adhesion moored the lower end of the organ to the diaphragm. Apart from this collapsed cake of lung there was nothing whatever in the right half of the thoracic cavity, the heart and other thoracic viscera being pushed right over into the left half (Figs 1 and 2) and the liver being depressed so far that no part of it remained within the costal cage (Fig. 3). Not only was this so, but the right pleural sac extended into the left side of the chest in the region between the second and sixth ribs (seen from the front,

FIG. 1.



A horizontal section through the superior mediastinum at the level of the third dorsal vertebra in a case of distension of the right pleura. The collapsed upper and middle lobes of the right lung are seen.

FIG. 2.



Part of a horizontal section of the same specimen at the ninth dorsal vertebra. A O R, Aorta. A D, Right auricle. S C, Coronary sinus. V D, Right ventricle. T, Thoracic duct. V S, Left ventricle. L L P, Ligamentum latum pulmonis.

as in Fig. 3), and opposite the fifth costal cartilage or the ninth dorsal vertebra (Fig. 2) it reached 4·5 centimetres beyond the mesial plane, forming a pocket behind the pericardium. Behind and on the right side of the liver the right pleural sac pushed the diaphragm beyond the limits of the costal margin (Figs. 3 and 4) in the form of a large sausage-like roll (Fig. 4, post-hepatic pleural sac) bent into a U-shape. In exposing the pleura from behind this sac was seen to extend two centimetres below the last rib.

After this general account of the results of the distension of the right pleural cavity let us briefly consider seriatim its effect on the heart and great vessels, the trachea,

dical Diary for the ensuing Week.

EDITORIAL NOTICES.

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed xclusively "TO THE EDITORS," and not in any case to any entleman who may be supposed to be connected with the ditorial staff. It is urgently necessary that attention be iven to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1907, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are :—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch" should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

present a considerable resemblance to "Grocco's triangle." Its broad base would be found just above the twelfth rib and it would taper gradually up to the second dorsal vertebra.

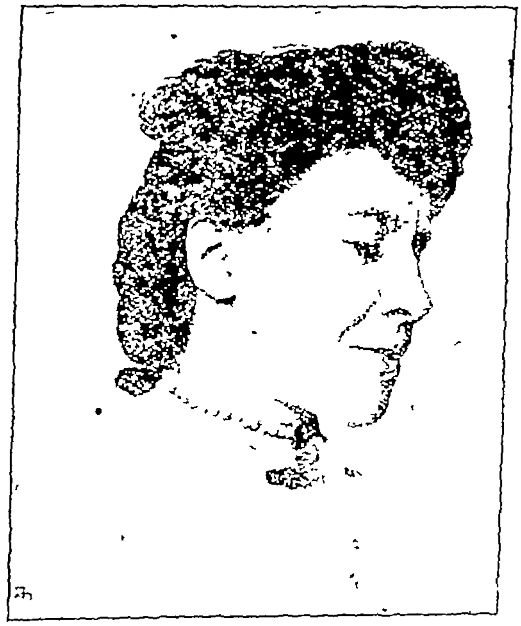
That this is the explanation of "Grocco's triangle" I do not for a moment pretend; but that it may be a factor of some importance in producing left-sided dulness in right-sided effusions must be patent to everyone who studies the accompanying diagrams.

Cairo.

EXCISION OF THE PAROTID GLAND WITH PRESERVATION OF THE FACIAL NERVE; ITS POSSIBILITY.

BY T. CARWARDINE, M.S., M.B. LOND., F.R.C.S. ENG.,
HONORARY SURGEON TO THE BRISTOL ROYAL INFIRMARY.

As far as I am aware there is no recorded attempt to remove the whole of the parotid gland with the preservation of the facial nerve. The following example, in which the operation was performed successfully, may encourage others to preserve the movements of the face in certain cases when removing the parotid gland. The question is rather an important one; for, unlike the conditions which obtain when the main trunk of the facial nerve is injured, there is no possibility of performing any kind of nerve anastomosis after injury to the ramifications of the facial nerve passing through the parotid gland. The distal filaments are too small to join with any other motor supply.



Patient after operation, showing the extent of contraction possible in the facial muscles

In 1905 a girl, aged 18 years, was under my care for a mixed tumour of the parotid gland which was shelled out so as not materially to damage the nerve. But it commenced to return two months afterwards and the patient came under my care again in May, 1906, with a tumour of the size of a large walnut. I proposed to her that I would make the attempt to dissect up the facial nerve and its branches first, and then to remove the whole of the parotid gland. By patient dissection with small sharp scalpels the nerve was successfully freed and held up by a loop of catgut, then the vessels were tied above and below, and the whole gland was completely excised. One or two distal filaments were accidentally ruptured, but the greater part of the nerve was preserved. Following the operation there was temporary facial paralysis, but in a couple of months the patient had twitchings at the angle of the mouth and kinæsthetic sensations. In about four months she had some movement of the facial muscles about the eye and mouth. A year afterwards she had good control of the facial muscles of that side, with very occasional slight twitchings. At this time very little inequality in the movements of the two sides of the face was discernible and the extent to which the patient could move the facial muscles of the side of the operation is depicted in the accompanying reproduction of a photograph which was taken during the phase of contracture.

The operation requires the expenditure of considerable time and care but the cosmetic results repay the trouble.

Bristol.

THE INCREASE OF DISEASES OF THE NERVOUS SYSTEM AND OF INSANITY.[1]

BY WILLIAM W. IRELAND, M.D. EDIN.

IT is a subject of common remark that in the present day there is a greater strain upon the nervous system, and this begins at an earlier period of life. The overtaxing at the schools, the increased amount of irksome study men have to go through in order to gain entry into the professions, the greater anxiety and hurry of life, the restlessness induced by the increased facilities of intercommunication, are all additional causes of irritation and depression. There is a craving for a variety of excitements and enjoyments, and a growth of artificial wants and a greater difficulty of earning sufficient wage and keeping up under incessant competition. The diffusion of education amongst all ranks, the struggles of aspiring persons amongst the poorer classes to rise in the world, the discontent and bitter wars of labour, entailing many disputes and frequent strikes and breaches of contract, the spread of the coöperative movement which is rendering the position of the private shopkeeper more difficult to hold, and the formation of big companies which crush out small businesses,—all these and some social antagonisms on which we have no time to dwell go to make this a harder and less agreeable world to many. At the same time the new conditions of our to-day life are not without their compensations. If we move about more we obtain more frequent amusement and change of air; if letters or telegrams too often claim our attention and disturb our repose, they often banish uncertainty and anxiety. Sounder views on dietetics have become known and drunkenness has become less prevalent. The decrease in intemperance in liquor amongst the middle and upper classes during the last half century has been very marked, and there is reason to believe that this decrease is extending to the lower classes. In general, we lead more secure lives than our fathers did, live under better laws, and have less to fear from injustice and oppression. There can be no doubt that during the last half century the condition of the working classes has greatly improved, their wages are doubled, while the purchasing power of money has increased for most articles, and they live under much better sanitary conditions. The result has been a notable diminution of the death-rate both in England and Scotland during the last quarter of the century. Nevertheless, it appears to me that the strain upon the nervous system is getting greater, at least for the middle and upper classes, and that therefore we may expect more nervous derangements and breakdowns. But to make a general opinion like this evident by exact inquiries is, on the face of it, very difficult.

Seven years ago I addressed to a number of medical men of experience and reputation the following queries: 1. Have you found since you began to practise medicine that there has been an increase in the relative *frequency of diseases* of the nervous system? 2. Have new *forms* come into prominence? 3 Have you *observed* any change in the type of old diseases? The answers which I received were far from settling the questions. Some physicians of great experience stated that they had noticed no increase in the relative frequency of nervous diseases; others were of opinion that nervous diseases had increased in frequency during the last 20 years. From all the answers which I have received I should judge that there has been no noticeable increase in nervous diseases in the country districts and in small towns, but there is some evidence that there has been an increase in those complaints in large towns, especially in functional disorders such as neurasthenia. Probably this increase affects some classes and persons of special pursuits more

An Address

ON

SOME PROBLEMS IN CONNEXION WITH THE SUPRARENALS.

Being the Address in Medicine delivered at the Meeting of the Canadian Medical Association at Montreal on Sept. 12th, 1907,

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

GENTLEMEN,—First let me express my sincere gratitude for the high compliment which you have paid me in asking me to give the Address in Medicine. The subject matter of an address in medicine must always be a source of some anxiety to those intrusted with the honour. It may either be on general lines and deal with the history, recent advances, future, and relations of medicine, or it may be more special and deal with a single subject. Each course has its own disadvantages, but after some consideration I have decided on a special subject and I must beg your indulgence for the following review of some problems in connexion with the suprarenal glands.

As is well known the suprarenals are composite glands consisting of two portions which are distinct from a developmental and from a physiological point of view—the cortex derived from cœlomic epithelium on the Wolffian ridge and closely related to the genital glands, and the medulla derived from the sympathetic and neuro-ectodermal in origin. These two portions are separated from each other in elasmobranch fishes, the cortical cells forming the single inter-renal gland and the medullary cells a series of paired bodies connected with the sympathetic (Swale Vincent).

THE CORTEX.

The cortex is larger than the medulla and is composed of epithelial cells the structure of which suggests a high degree of functional activity; in Biedl's hands experimental removal of the cortex, the medulla being left intact, was followed by death of the animals; and it is stated that compensatory hypertrophy of accessory suprarenals, when this occurs after excision of the main glands, is solely cortical. These considerations strongly suggest that the cortex has some important function and that it is essential to life, but in what exact way is as yet unknown. The most certain point about the cortex is that it is quite unlike the medulla. Its cells contain fat and lecithin but do not give a green colour with ferric chloride (Vulpian's reaction) or a brown colour with chromic acid as the chromaffine cells of the medulla do. Physiologically extracts of the cortex are quite inactive and do not raise the blood pressure. Our knowledge as to the function of the cortex is very imperfect, but some arguments can be adduced in favour of each of the three following views—namely, that it may be concerned (1) with growth and development, especially of the sexual organs; (2) with neutralising poisons; or (3) in some manner with the internal secretion of the medulla—adrenalin.

1. *The relation of the cortex of the suprarenals to growth and development, especially of the sexual organs.*—It is now known that there is a definite group of cases in young children, the peculiar feature of the cases being that a primary tumour of the suprarenal body (hypernephroma, mesothelioma) (Woolley[1]) is associated with excessive development of the organs of generation, hair, and fat. Bulloch and Sequeira[2] have collected ten cases, all but two under eight years of age, two in males and eight in females, showing this precocious development in association with a hypernephroma which, in some of the cases at any rate, was derived from the cortex of the suprarenal; further researches will naturally be directed to determining whether hypernephromas of cortical origin are, as suggested here, specially associated with exaggerated growth, while hypernephromas arising in the medulla of the suprarenal show no such association. Bulloch and Sequeira have indeed collected 12 cases of hypernephromas in children who did not show any signs of premature development and in some of these cases the tumours, described as sarcomas or lymphosarcomas, were definitely regarded as arising from the medulla of the gland. It must, however, be noted that in adults cortical hypernephromas, which are probably more often seen in the kidney (renal hypernephromas or "adrenal rest" tumours) than in the main adrenal gland, are not associated with the notable genital development, hirsuties, and obesity seen in children. As rare exceptions to this rule attention may be directed to Thornton's[3] case of a woman, aged 36 years, who was covered all over with black silky hair and had to shave her face, and to a somewhat similar case in a female lunatic, aged 32 years (Richards[4]). In passing it is interesting to note the rarity of renal tumours of adrenal origin in children as compared with the incidence of these tumours in adults and with the incidence of hypernephromas in early life. But although excessive genital development and growth of hair in a child should always suggest the existence of a cortical hypernephroma, it must be remembered that these striking signs may exist without any such lesion in the suprarenals (Guthrie and Emery).[5] As bearing on the connexion between exaggerated cellular growth of the suprarenal cortex and the development of the genital organs, a few cases are on record in which suprarenal hyperplasia has been found in individuals with such excessive size of the clitoris that they were erroneously regarded as males. Further, enlargement of the suprarenals has been noted in animals during periods of sexual activity and pregnancy, and it has appeared to me that there is a close resemblance between the cells of the suprarenal cortex on the one hand and the luteal cells normally found in corpora lutea and exceptionally in luteal cysts on the other hand. This resemblance both histologically and morphologically has been insisted on by Mulon[6] who, from observations on guinea-pigs, speaks of the corpus luteum of pregnancy as a temporary cortical suprarenal. It is interesting to compare these developmental anomalies accompanying some cortical hypernephromas with acromegaly which is usually associated with hyperplasia or adenomatous change in the anterior lobe of the pituitary gland. For, as Schäfer and Herring[7] point out, the anterior lobe of the pituitary and the cortex of the adrenal are alike in several particulars—namely, in the glandular character of their epithelium, in the physiological inactivity of their extracts, and in ensheathing collections of neuro-ectodermal cells (the posterior or infundibular lobe, and the adrenal medulla) which, on the contrary, possess extremely active physiological extracts. As bearing in a somewhat remote manner on the relation of the suprarenal cortex to the growth of the body it may be mentioned that evidence is accumulating to show that primary malignant growths of the cortex, like primary carcinomas of the thyroid, have a special tendency to produce metastases in bone (Scudder).[8] This similarity to the thyroid is of interest in the light of the well-established influence of the thyroid on skeletal growth.

Conversely, hypoplasia of the suprarenals has been found in anencephalous monsters; but the relation between the two developmental abnormalities is doubtful, Zander[9] regarding the lesion of the nervous system as primary and Alexander[10] considering the suprarenal defect as primary. Very possibly, however, the failure of development is concomitant; in any case this association is not a strong argument in support of the influence of the suprarenal cortex on the growth of the body, for the hypoplasia of the suprarenals appears to affect the cortex and medulla equally and not to be specially marked in the cortex. Hypoplasia of the suprarenals has been met with in a few cases of retarded sexual development, and in their case of osteogenesis imperfecta Lovett and Nichols[11] found the internal organs normal with the exception of the small size of the suprarenals. The view has been put forward, but without any the million. In the quinquennium 1886–90 the mean number of suicides was 227, giving 56·4 per 1,000,000. In 1905 the number of suicides had risen to 305, being 65 to the million.

Increase of insanity in England.—The steady and progressive increase of the number of the insane throughout Europe has attracted popular attention. Much of this increase is due to the collection of lunatics in special asylums, and to their accumulation, owing to better care giving some of them a longer life; but this fails to explain the whole rise, and physicians like Koch, Kollman, Oettingen, Lunier, and Kraepelin, who have devoted much time and care to examine the statistics, have come to the conclusion that there has been a real increase in the absolute number of the insane. Unhappily the Commissioners in Lunacy for England long ago took a different view, and as the number of lunatics they had to deal with perversely kept on increasing, they have had much care to explain away their own statistics. There were always some men well acquainted with the subject to show that there was a real increase, and the phenomenal rises in the number of official lunatics in 1897 and 1898 opened many eyes. In 1897 there was an increase of 2919 registered lunatics in England and Wales and in the next year an increase of no fewer than 3114. The rise in the number of general paralytics was very marked. In 1859 there were in England and Wales 36,762 certified insane persons—one official lunatic to every 536 persons; in 1869 there was one to every 418; and in 1879 one to every 363. In 1889 there was one registered lunatic to every 337 persons, and in 1893 it was one in 302. In 1906 there was one lunatic to every 283 persons, the proportion being 35·31 per 10,000 of the population, whereas in 1859 it was only 18·64 to the 10,000. The increase since 1859, in proportion to the general population of the country, has been 231 per cent., while the increase of the population has only been 75·4 per cent.

The Commissioners in Lunacy have no means of ascertaining the total number of the insane in England beyond the census returns. They themselves observe in their report for 1904 that they have no detailed information of those pauper lunatics who are in workhouses or in receipt of outdoor relief or are residing with relatives. The admissions to lunatic asylums have risen from 4·71 per 10,000 of the population in 1869 to 6 56 in 1904 Unfortunately we cannot learn how many of these were readmissions.

England.

Census 1871 = 69·019 of the insane.
1881 = 84·503
1891 = 97·383
1901 = 132·624

Turning to the census returns we find a full confirmation in the increase of the number of insane persons in England and Wales. In 1871 there was stated to be one insane person to every 329 of the population; in 1881 there was one insane to every 307; in 1891, one to every 298; and in 1901, one to every 245 sane persons. The Commissioners observe that comparing the ratios in the census of 1891 with that of 1901, the increase in the ratio of the insane fraction of the population was 10 9 per cent. (males 12·2 and females 9·7) and they maintain that the growth of the insane was practically confined to the "pauper" class.

Dr. George H. Savage, in his third Lumleian lecture before the Royal College of Physicians of London,[3] gave as his opinion:

> "There is sufficient evidence to show that there is a steady increase in the numbers of the insane in England, Ireland, and Scotland, though in the most recent reports there has been shown to be a reduction in the proportion of insane recognised, but I shall point out reasons for the apparent reduction. Among the more wealthy in England particularly there is a growing disinclination to send their insane relations into asylums. There is certainly no change in relationship to the feeling against asylums and against certification. With the more educated the dread of the transmission of insanity is very great, but if the malady is called by any other name and treated by other than alienist physicians people are satisfied."

Dr. W. H. Bowes[4] agrees with the general impression that there is some increase in insanity, but not enough to create alarm. He points out that there is in a report on the high rate of lunacy in Yorkshire[5] a much larger proportion of insane to sane among the agricultural labourers than among miners and city dwellers. He shows that for 30 years the agricultural counties have shown most pauperism and most insanity. He thinks that marrying in and the poorness of the living and generally depressing vital conditions account for this.

Increase of insanity in Scotland.—The same steady increase in the number of the insane has been going on in Scotland as in England, and there was the same startling rise in 1897 and 1898 which distanced all arithmetical explanations. It is stated in the lunacy report for January, 1906, that since 1858 the number of lunatics under the jurisdiction of the Scottish Lunacy Board has increased by 200 per cent., while the increase of population during the same period has been 56 per cent. In their report for January, 1906, the Commissioners made the pleasing announcement that for the first time there was a retardation in the increase of insanity in proportion to the population during the last three years. In 1906 the number of registered insane (including some imbeciles in institutions) was 17,450; of these 2549 were maintained from private sources, 14,850 by parochial rates, and 51 by the State. This showed an increase of 209 from the preceding year, but allowing for the growth of the population the Commissioners claimed that there was no relative increase. In the proportion of private patients, which had been steadily but slowly rising, the rate of increase was also arrested. During these years the death-rate was considerably higher and there was a falling off in the numbers discharged recovered and unrecovered.

In assuming a decrease in the number of the insane the Commissioners take no note of the numerous patients admitted and treated in the new Glasgow observation wards from their commencement in June, 1904, till May, 1907. These are not certified as lunatics. It is difficult to bring the returns, as they have reached me, into one plane with the Lunacy Blue-book. Let us give an example: from June 15th, 1904, till May 15th, 1906, there were 1077 admissions to the new wards in the Glasgow parish hospital. Of these only 302 were certified and transferred to the asylum, leaving a total of 735 discharged (recovered, improved, or by death) and 40 remaining in hospital. But for the existence of these wards the 735 discharged would all, or almost all, have been certified insane at the very outset and sent to the asylum. The Commissioners' statistics would have been increased accordingly.

Making a wide allowance for deductions and eliminations it may be said that 320 of these patients would have been certified and have been included in the Commissioners' return. We may distribute these 320 patients as follows: June to December, 1904, 80; January to December, 1905, 160; and January to May, 1906, 80. We have also to count the uncertified patients treated in the Govan parish wards which were opened on August 29th, 1905. If these returns be included it is clear that instead of there being a retardation in the number of insane persons in Scotland the augmentation is still going on.

It is disappointing to know that in spite of all the money spent on buildings and furnishings, the care, medical skill and research, and official inspection, there is no increase in the proportion of recoveries in the British asylums and the death-rate is not diminishing. In some Scottish asylums receiving patients from large towns the rate of mortality has been rising, which is attributed to a worse set of cases coming in. The deaths from diseases of the nervous system for every thousand of the average numbers resident have been increasing in the Royal Asylum of Edinburgh for the last 33 years. During the past five years up to 1905 the mortality has been 65·8 and in the year 1906 it reached the unprecedented figure of 85 7 per 1000, or more than double the old proportion. The average number of deaths for the same kind of cases for the whole Scottish asylums is stated to be 33·4. As Dr. T. S. Clouston remarks in his able Annual Report for 1906: in Scotland "deaths from diseases of the nervous system are increasing in the general population in modern times; but that increase is small as compared with this increase of fatal nervous diseases sent to asylums from Edinburgh. No doubt it is one of the problems of modern life to keep the nervous machine going at high pressure and at the same time to prevent its breaking down prematurely."

Increase of insanity in Ireland.—The inspectors of lunatics have had to record an increasing number of the insane with a decreasing population. From the census returns from 1851–1901 the population of Ireland fell from 6,552,385 to 4,458,775—that is, 32 per cent., while the number of the insane rose from 9980 to 25,050, or 151 per cent., and the ratio of insane to population from 15·2 to 56·2 per 10,000, a rise of 267 per cent. The proportion per 100,000 of the re no symptoms resembling those produced by overdoses of hyroid extract or thyroidism, and so far as this goes it would ppear that if there be normally a balance between the nternal secretions of the suprarenal and thyroid glands, his balance is partially maintained, possibly by diminished hyroid secretion or by some neutralisation of the active hyroid secretion by the tissues of the body, when the nternal secretion of adrenalin fails entirely. There is, of ourse, one manifestation common to Addison's disease and xophthalmic goitre—namely, pigmentation—but it is very ifficult, in the present state of our knowledge, to explain this s the result of one and the same process in the two diseases. t is much more likely that in both cases there is overxcitation of the sympathetic nerves, in exophthalmic goitre by n excessive and abnormal thyroid secretion and in Addison's isease by a toxæmia possibly depending on inadequacy of he hypothetical antitoxic function of the cortex of the uprarenals.

---

(*b*) Diminution in the amount of adrenalin. This may be onsidered under the heads of (1) chronic inadequacy; (2) cute inadequacy; and (3) relative inadequacy. (1) Chronic inadequacy. The existence of cases of larval or frustrate myxœdema has now long been recognised; the condition has also been called benign hypothyroidism. The most convincing proof of its existence in a given case is improvement after the administration of thyroid extract. Similarly there is a condition of deficient adrenalin secretion. Possibly in some cases this defect of the adrenalin-secreting cells may be congenital; and it has been suggested that the status lymphaticus and hæmophilia are thus explained (Wiesel). A condition of deficient secretion of adrenalin, or partial medullary inadequacy, is probably more commonly acquired and the result of morbid changes in the medulla. These changes may be due to tuberculous, syphilitic, or cancerous invasion secondary to disease elsewhere in the body; or to toxins conveyed from other parts of the body—for example, the lungs in cases of tuberculosis may so act on the suprarenals as to produce degeneration and fibrosis; or, again, as the result of acute infections, such as staphylococcal or pneumococcal, the suprarenals may be permanently damaged and suprarenal inadequacy be established; this sequence of events is analogous to chronic nephritis after an acute attack of nephritis. To this condition of suprarenal inadequacy the name Addisonism has been applied by Boinet,[20] who in 37 cases of pulmonary tuberculosis manifesting Addisonism found the suprarenal bodies fibrosed in 30, infiltrated with small tubercles in four, and with caseous tubercles in three. This conception has some bearing on the pigmentation which so commonly accompanies advanced pulmonary tuberculosis and often raises the question as to the existence of Addison's disease. Everyone is familiar with these cases, but as the symptoms are not sufficiently marked to justify a diagnosis of Addison's disease, the tendency has been rather to put the factor of the suprarenals aside in attempting to explain the melanodermia of advanced pulmonary tuberculosis. Since it has been shown that the suprarenal medulla may be devoid of adrenalin in exhausting diseases (Mott and Halliburton) there appears to be reasonable ground for the view that Addisonism may here be present. Boinet recommends adrenalin in these cases; in order to determine whether there is or is not suprarenal inadequacy the effect of adrenalin on the arterial blood pressure should be estimated, for O. F. Grünbaum[21] has shown that in healthy persons suprarenal extract has no effect on blood pressure, but that a rise of blood pressure after the administration of suprarenal extract indicates suprarenal inadequacy. This method of diagnosis and treatment deserves further trial. But it must be borne in mind that though low blood-pressure and asthenia may be counteracted by adrenalin, the pigmentation has not been proved to depend on want of the internal secretion of the medulla, and hence it cannot be anticipated that the administration of adrenalin will remove the melanodermia, which may, indeed, depend on a concomitant lesion of the cortex. Just as numerous symptoms have been referred to benign hypothyroidism, so it is not illogical to suppose that various conditions, characterised by low blood-pressure and debility both of the involuntary and voluntary muscles, may depend on an insufficient supply of adrenalin. Thus it has been suggested, but by no means proved, that cyclical albuminuria and forms of neurasthenia associated with low blood-pressure are manifestations of adrenal insufficiency.

(2) Acute adrenal inadequacy. It occasionally happens that death occurs suddenly in patients suspected to be the subjects of Addison's disease on account of some abnormal pigmentation, but without any definite constitutional symptoms; or that persons previously in fair health and certainly not known to have any disease suddenly become acutely ill, often with convulsions, and die rapidly from collapse. In some of these cases tuberculous disease of the suprarenal bodies is found at the necropsy and death is perhaps certified as due to Addison's disease. Though this conclusion is in the main correct it does not explain the fulminating character of the termination. It is probable that this is due to some form of acute infection attacking the suprarenal glands and leading to suppression of their functional activity, and it can easily be understood that this will occur more readily when the amount of suprarenal medullary substance available has been previously curtailed. In many acute infections, especially in diphtheria, the micro-organisms or toxins produce acute changes, such as cloudy swelling, necrosis, and leucocytic infiltration, in adrenals previously healthy. In some instances the damage is so acute that hæmorrhage occurs into the glands. This acute condition of adrenal hæmorrhage has been specially studied in children, and it has been suggested on the one hand that rapidly fatal hæmorrhagic small-pox explains some of the cases; thus, of ten recorded cases seven were unvaccinated (Riviere[22]), and on the other hand that the condition is due to food poisoning or an acute toxæmia of unknown origin and is possibly a distinct disease (Dudgeon[23]). Acute adrenal hæmorrhage may also complicate various fevers such as diphtheria, enteric, pneumonia, and erysipelas. The hæmorrhages may be punctate, infiltrating or massive, unilateral or bilateral. The most characteristic symptoms of these adrenal hæmorrhages are sudden onset with fever, violent pain in the hypochondrium radiating to the loins, convulsions, vomiting, diarrhœa, and, later, tympanites, collapse, and death within 48 hours from the onset. No doubt damage is done to the adjacent abdominal sympathetic by the hæmorrhage, and thus clinical manifestations analogous to those of hæmorrhagic pancreatitis are produced. Cutaneous purpura is sometimes associated with hæmorrhage into the adrenals, as in variola, and it would, at any rate at first sight, appear probable that the same underlying cause—toxæmia or bacteriæmia—is responsible for both sets of hæmorrhages. It has, however, been thought that the changes in the adrenals are primary and the purpura secondary (Loeper[24]), that purpura may stand in the same relation to acute destruction of the suprarenals as pigmentation does to chronic destruction (Dudgeon), and that the proper treatment is to give adrenalin. It is worth while to inquire to what extent the low blood pressure and circulatory failure seen in acute febrile diseases are the result of temporary suprarenal inadequacy, brought about by the action of bacterial toxins on the cells of the medulla of the suprarenal bodies. The action of toxins on the heart muscle cannot be questioned, but it is conceivable that some of the loss of vascular tone in fever is due to a want of adrenalin and that it is not entirely the result of the direct action of toxins on the vascular system. This question is of practical importance as bearing on the advisability of giving adrenalin in acute diseases with threatened failure of the circulation. That the amount of adrenalin in the suprarenal glands may be greatly diminished by acute disease has been shown by testing the glands physiologically (Mott and Halliburton[25]). The medulla of animals poisoned by diphtheria is devoid of adrenalin, as shown by the colour reaction with chromic acid (Elliott and Tuckett[26]), and it had previously been found empirically that adrenalin was of great value in the cardiac failure of diphtheria. An obvious objection to the administration of adrenalin in such conditions is that if it increases the peripheral resistance it will of necessity give the failing left ventricle more work to do and so be harmful rather than beneficial. I have, however, for some considerable time been in the habit of

CASE 1.—The patient, a married woman, 43 years of age, consulted me in December, 1900. Her family history was unimportant. She had always been active and sober. She had had no family. Many years ago she had typhoid fever. For some years she suffered from metrorrhagia. She underwent subperitoneal hysterectomy in 1897 on account of uterine fibroids. For several years she had had much anxiety on account of a sick husband, and was much weakened by the operation and all that had preceded it. About the middle of 1898 she began to notice tenderness in the feet, neuralgic pains in the limbs, and vague pains in the joints. About six months later she noticed distinct swelling of the wrists and knees, then of the finger-joints of both hands, and then of the ankles. By degrees every joint in the body became stiff and painful, including the intervertebral, temporo-maxillary, and sacro-iliac. 12 months later, notwithstanding treatment at Bath, Buxton, and elsewhere, she wasted to a mere skeleton and was unable to move hand or foot; she said her feet felt "dead" and she was provided with a water bed. She became very depressed and neurasthenic. Her digestion was bad, her skin was harsh and scaly, her fingers were wasted, and the skin over them was thin and glossy. She was unable to write or to do needlework and was pronounced by several medical men to be incurable. On March 18th, 1901, I persuaded her with some difficulty to try the effect of counter-irritation of the spine by means of blisters. Two were consequently applied, each 4 by 1½ inches in size, one on each side of the spine, the upper edges opposite the tenth dorsal vertebra, with a view to influencing the lumbar enlargement of the spinal cord. The blistered surfaces were kept discharging for 14 days by means of savin and resin ointments applied daily. On April 12th the patient said that the pain in the knees and legs was less and passive movements of the legs could be carried out with greater ease and thoroughness than before. On the 16th blisters of the same size were applied on each side of the cervical enlargement of the spinal cord. On the 19th she said that she had more sensation in her feet. The blistered surfaces were treated with savin and resin ointments as before and kept open for 14 days. On May 7th there was found to be all-round improvement. The patient wrote a long letter to a friend. It was the first time she had used a pen for over a year. On the 28th the knees were much less swollen. On June 19th she was much better and was allowed out of doors several hours daily. The digestion was better and she was gaining weight. On the 20th blisters were again applied to the lumbar region and treatment was carried out as before and afterwards to the cervical region. On July 18th the knees were much better; the right leg could now be straightened; it was much bent previously. On the 30th the patient was able to walk a little. On Sept. 16th she went to Buxton. "Chair patient." On Feb. 5th, 1902, she could do part of her own housework. In September she went to Buxton no longer a "chair patient" but saw several patients in chairs who had been able to walk the year before. The patient eventually resumed her household duties, even doing her own washing, and has kept well nourished and active ever since. I attribute this woman's recovery entirely to the action of the blisters.

CASE 2.—The patient, a married woman, had spent her early life in domestic service. When 30 years old her right knee swelled very much and was highly inflamed; this subsided under long-continued leeching and poulticing; it was probably of septic origin and was always stiff afterwards. The hip of the same side became painful but remained useful for many years. Later the opposite knee became gradually stiff and tender but was never much inflamed. By degrees all the joints assumed a rheumatoid condition until at last, at the age of 55 years, she was unable to do any work except a little light work about the house. On examination by me, on June 25th, 1905, the ankles, knees, and wrists were found to be much swollen, with ganglia on the tendons, and pouches of synovial swelling about the wrist. The finger-joints presented the characteristic fusiform swelling and the hands were much distorted. Pain was so great in the right hip that she was unable to lie on that side. She was just able to totter about. Her eyesight was very weak and she was obliged to wear spectacles. She had not been out of her bedroom for three years. She was treated by continuous counter-irritation to the spine as in the former case, and can now (August, 1907) go up and down stairs with ease; she walks out of doors and has gained considerable weight, can do needlework without spectacles, and says her health is splendid. No other treatment was tried in this case after applying the blisters, neither drugs nor special diet, as I determined to test what effect the blisters alone would produce.

CASE 3.—The patient, a married woman, aged 45 years, had had polyarticular rheumatoid arthritis following several attacks of rheumatic fever. She was obliged to give up her work as a charwoman. She was treated by continuous counter-irritation to the spine for one month from June 5th to July 3rd, 1905, and was cured. She resumed work and has kept at it for upwards of two years. She is now in excellent health.

CASE 4.—The patient, a man, aged 74 years, had polyarticular rheumatoid arthritis of several years' duration. He gave up all work at the end of 1905. He was treated by continuous counter-irritation to the spine for 24 days in March, 1906. He had no other treatment whatever. He was greatly benefited and resumed his work as a road-sweeper in May, 1906.

CASE 5.—The patient was a housemaid, aged 40 years. She first noticed rheumatoid symptoms 20 years ago. She was at last obliged to give up work on account of pain and weakness. She had tried practically every known kind of treatment at Bath and elsewhere, including Tallerman treatment, which produced little benefit. Normal perspiration even in summer had been suppressed during the last three years. Her skin was dry. Eventually she consulted me in January, 1907. She was treated by continuous counter-irritation to the spine for one month from February to March. No other treatment was tried. All pain and swelling disappeared and normal perspiration returned. She returned to, and is still at, work. She reported a short time ago (June 23rd) that her health continued to be satisfactory. She was able to walk several miles with ease.

In all my other cases except one the results have been very striking. They were not selected but taken just as they came, irrespective of age, condition, or duration of the complaint. Some authorities disapprove of blisters for patients in feeble health, but several of my patients were extremely feeble. In only one case, a patient much subject to dysuria, did strangury occur. It only lasted a few hours and yielded to copious water-drinking and the administration of hyoscyamus.

Finally, I would point out that beneficial results in these cases must not be expected from slight and transient counter-irritation. The irritation must be pronounced and prolonged *and applied at the right spots.*

Bournemouth.

NOTES ON CERTAIN FATAL FORMS OF PHARYNGEAL DIPHTHERIA.

BY ALFRED HARRIS, M.B., CH.B. VICT., D.P.H. CAMB.,
ASSISTANT RESIDENT MEDICAL OFFICER TO THE CITY HOSPITAL FOR INFECTIOUS DISEASES, NEWCASTLE-ON-TYNE.

THERE are certain forms of diphtheria in which from experience a fatal ending can with certainty be predicted. The symptoms presented by these cases are as follows: 1. A greyish colour of the face, which in addition presents an anxious expression. 2. Vomiting. This seems independent of food and is not accompanied by nausea. It presents a similarity to cerebral vomiting. The vomited matter is yellow or green. 3. Abdominal pain. This is sometimes very severe. It is, however, nearly always present in these cases. It is referred to the umbilicus. No abdominal tenderness can be elicited. 4. Albuminuria. This is generally present and often to a large amount (from one-sixth to a quarter). There are no tube casts. 5. Suppression of urine is the rule in these cases. 6. Alteration in the rhythm of the heart sounds. This appears after the vomiting has set in. One of the sounds of the heart is reduplicated, thus giving an imitation of the sound to be heard when a horse gallops. The patients are generally very restless and consciousness is maintained until the end. The membrane on the throats in these cases is dark coloured and the smell of the breath is most offensive. During the last two years there have been eight of these cases admitted to the Newcastle City Hospital for Infectious Diseases. The patients were admitted at different periods of their illness but, as a rule, from the fourth to the sixth day. In Newcastle the patients rarely come into the hospital at an wild speculation, but it may be mentioned for what it is worth, that possibly intestinal toxins may so act on the cells of the adrenal medulla as to produce an internal secretion of such an abnormal character that the normal process of transformation of any excess into an inactive body, as suggested by Giofiredi, cannot be carried out by the tissues. The excess of such an abnormal adrenalin might conceivably cause high arterial pressure, arterio-sclerosis, and the allied morbid changes.

An Address

ON

THE PREVENTION OF MALARIA IN BRITISH POSSESSIONS, EGYPT, AND PARTS OF AMERICA.

Delivered in Section VII. of the Fourteenth International Congress of Hygiene and Demography held at Berlin, September, 1907,

BY RONALD ROSS, C.B., F.R.C.S. ENG., D.P.H., F.R.S.,

PROFESSOR OF TROPICAL MEDICINE, UNIVERSITY OF LIVERPOOL.

I.—PRELIMINARY.

ALMOST exactly ten years have now elapsed since the parasite of malaria was first detected in anophelines. This discovery, confirmed and amplified in many countries, suggested many methods for the prevention of the disease; but unfortunately, although science may indicate methods of prevention, local Governments are not always willing to undertake the trouble and expense required for the work. It is very advisable, then, to examine how much various Governments have actually done during this period in several parts of the world to preserve mankind from the vast amount of sickness and mortality occasioned by so widespread a malady and to consider what action may be taken to encourage more energetic efforts in the future. In attempting this task, however, I propose to confine my remarks to those countries in which the progress of events is best known to me—that is, principally to the tropics; but at the same time fear that I must give the history in considerable detail, without which my conclusions will not perhaps be as clear to others as they seem to be to myself.

In 1897–99 I was able to observe in several parts of India that numerous species of anophelines (in two of which I had previously cultivated the crescent-bearing parasites) breed mostly in natural collections of water lying upon the surface of the ground, and not, as many other common varieties of gnats do, in vessels and cisterns.[1] This fact at once suggested the full explanation of the laws known from the time of the ancients—that malaria is generally connected with terrestrial water, and may be reduced by drainage. But at the same time, while it re-established the old prophylaxis by drainage, it rendered it more simple, cheap, and yet precise. No longer driven to the expensive task of draining the whole expanse of a malarious area, we were now able to confine our operations, often with a great saving of money, only to those particular pools which are suitable for the larvæ of the insects, and which in many places I had already observed to be comparatively few and small. Consequently I did not hesitate to advise the Government of India (in a report dated Feb. 16th, 1899) to adopt this important measure in the principal malarious towns and military stations.[2,3] At the same time, as already empirically known, the use of mosquito nets during sleep was obviously a valuable means of personal prophylaxis. Shortly after writing this report I left India, and a few months later (July, 1899) proceeded with two colleagues, Dr. H. E. Annett and Mr. E. E. Austen, to the British colony of Sierra Leone, where we hoped to indicate more exactly the details of this perfected system of drainage-prophylaxis. We immediately ascertained by my methods previously elaborated in India that *Pyretophorus costalis* and *Myzomyia funesta* carry all the species of the parasites of man in that part of Africa; that these mosquitoes breed principally in small but numerous collections of water on the ground; and that it would be a comparatively easy task for the authorities, with all the resources at their disposal, to remove these breeding-places within the city of Freetown and thus to reduce the mosquitoes and the malaria together. In order to help them in this task we indicated for the first time the peculiar attitudes of the anopheline larvæ and adults which enable anyone to recognise them at sight; the special characters of the pools in which they breed; and the exact methods by which these pools should be dealt with; and we furnished them with a complete map of the principal breeding places. Our reports gave the original full exposition of the antimosquito prophylaxis of malaria, which since then has become the basis of all such work in many parts of the world.[4,5] Not being authorised, however, to undertake the work ourselves, all we could do was to advise, and we then returned to England hoping that the Government would act upon our suggestion.

In the meantime my Indian researches had been followed with enthusiasm in Germany and Italy. In the autumn of 1898 Koch and the Italian observers, who had made so many beautiful studies of the subject, were able to confirm and to extend the original investigations. They immediately suggested another great system of malaria-prophylaxis—that by quinine. It was argued that if all the persons in a community who suffer from malaria are sought out and efficiently treated with quinine the parasites will diminish so greatly within the community that the mosquitoes, however numerous they may be, will no longer become infected, and will so cease to convey the infection to healthy persons. Without delay, the Germans, led by Koch, and the Italians, led by Celli, sought to give practical effect to this logical suggestion. At the same time, Celli especially advocated the general protection of houses by means of screens of wire gauze.

It is not my function to-day to follow the labours of these distinguished workers. The problem in malarious British colonies, which are mostly tropical and inhabited by dark races, is not the same as in Italy—a fact which is often forgotten by academical sanitarians. Such races cannot easily be persuaded to submit to continued medication by quinine and are much too poor to provide screens for their houses, and even Europeans in the tropics frequently reject both measures with obstinacy. On the other hand, drainage-prophylaxis demands no such compliance from the public. As I have frequently pointed out,[6] local authorities can drain, or otherwise treat, anopheline pools without asking the consent of any one. The people are not required to take any drug for months, or to pay for expensive appliances to their windows. Moreover, mosquito reduction tends to remove yellow fever and filariasis as well as malaria, banishes a source of constant personal irritation, and, no less important, compels local sanitary departments to keep a close watch on all parts of the area in their charge. On the other hand, of course, we cannot expect drainage to be undertaken everywhere, in the open fields or the wilderness; it is principally applicable to towns—that is, to places where the money spent upon it is likely to benefit the largest number of people; for the camp, the farm, the plantation, the isolated house, and the petty hamlet the other measures must frequently be fallen back upon. As a rule, however, for tropical towns mosquito reduction where it is possible has always promised to be the most useful and, in the end, the most economical system of all; and, of course, the other measures may often be adopted, at least partially, in addition. Thus the ideal procedure for towns in the tropics consists (1) in the removal of mosquito-breeding waters; (2) in the treatment of old cases of malaria with quinine; and (3) in the protection, as an additional safeguard, of hospitals, barracks, jails, and as many houses as possible with wire gauze. To these we must add, as insisted upon by Stephens and Christophers, the principle of segregation for Europeans.

But however desirable mosquito reduction seemed to be, my proposals to adopt it were everywhere met at first with necessary for proper digestion, and that any good in the shape of improved appetite, &c., which may result from the use of trypsin does so by supplying this deficiency. Case 2 seems to uphold this but in none did we find any prolonged good influence either on the pain or any other symptoms of the disease, and without doubt compared with these the cases treated by x rays alone are in a much better condition at the present time.

CASE 1.—The patient, a female, aged 69 years, was admitted to the x ray department of the London Hospital on June 12th, 1907. Her previous health had been good and there was no history of tubercle or of cancer. Commenced eight years previously with retraction of the left nipple. The breast and nipple had gradually been drawn upwards to the left axilla. The only treatment which she previously had had was boric lint and powders. The chief symptoms complained of were pain along the arm, which was worse at night, swelling of the arm at times, and the fœtid smell from the breast, all of which had been getting worse during the previous three months.

On admission there was a large cancerous mass consisting of breast and glands all drawn up towards the axilla, with a deep fissure along its surface, at the bottom of which was a fungating mass. The whole condition was atrophic and smelt horribly. The patient was considered to be quite inoperable and was treated by x rays and hypodermic injections of trypsin co. She had had 22 applications of x rays three times a week on alternate days and 23 injections of trypsin on the same days, commencing with doses of 15 minims for five doses and gradually working up to 30 minims, which she had on the last nine occasions. During the period after the first few injections she had some relief from pain, but after every subsequent injection the pain increased, the swelling of the arm became greater and the sleeplessness worse than ever, so much so that she continually required morphine. The wound was daily irrigated with hydrogen peroxide (ten volumes) which improved the smell and fungoid state, but otherwise the condition was much worse, other enlarged glands having appeared in several places. The swelling of the arm was less than it had been a few weeks previously owing to careful bandaging from the elbow upwards to prevent or lessen the œdema. The condition is spreading and the appetite extremely bad, as it has been all during the injection treatment. In this case no actual suppuration occurred, but there were lymphangitis of the arm and local acute inflammation on several occasions.

CASE 2.—The patient, a female, aged , was admitted on June 12th, 1907. The family history was good and her previous health had been good. The left breast was removed on April 8th, 1907. The usual scar was present; there was a recurrence in the axillary glands with some slight swelling and œdema of the arm. The patient complained of great pain when lying on the left side. She was given 20 applications of x rays and 15 injections of trypsin co. She experienced a great increase of pain after every injection. There was induration each time, with frequently a slight rise of temperature and the appearance of an impending abscess which generally resolved. The appetite was bad all through and did not improve in the least. During treatment the patient has become extremely ill, wasting rapidly, with a local and general dissemination, fresh nodules being evident in the scar, in the other breast, in the axilla, and on the surface of the abdomen, the back, and the legs. The only relief obtained was when under the influence of opium.

CASE 3.—The patient, a female, aged 71 years, was admitted on June 7th, 1907. She had been operated on for carcinoma of the right breast in November, 1906, and first noticed lumps in the skin in April, 1907. Five weeks before admittance the arm had begun to swell. On admission the arm was very much swollen and there were hard nodules in the skin around the scar and enlarged glands in the axilla and above the clavicle. She was given 20 sittings of x rays and 17 injections of trypsin co. For about the first three weeks she felt much better in herself and there was a great improvement in her appetite. She said that there was some pain after each injection but it was different from the pain which she had been suffering and she described it as if one pain killed another. This good effect soon passed off and the pain became worse than ever before, causing her to get practically no sleep at nights. There was generally a throbbing and burning pain after each injection, though no actual suppuration occurred. The condition is rapidly getting worse; the nodules were spreading in the skin around and the lumps in the axilla and above the clavicle are much larger and are increasing in size. The only rest which she is now able to obtain is by the aid of morphine.

CASE 4.—The patient, a female, aged 56 years, was admitted on May 23rd, 1907. The left breast had been removed. The usual scar was present but there was only one questionable lump to be felt in the axilla and this was difficult to distinguish from a thickened axillary fold in the scar of operation. She was given 15 sittings of x rays and 13 injections of trypsin co. in doses gradually worked up to 30 minims. The pain was increased on every occasion, sleep was prevented, the appetite did not improve a bit, and there was no good result. During treatment several fresh definite lumps appeared in the axilla. Since discontinuing the trypsin the pain in the breast and the arms has been less.

A CLINICAL STUDY OF PARALYSIS OF SUDDEN ONSET AND WIDE DISTRIBUTION:

FIVE CASES OF LANDRY'S PARALYSIS; ONE CASE OF ACUTE INFECTIOUS MULTIPLE NEURITIS; AND ONE CASE OF MYASTHENIA GRAVIS.[1]

BY J. W. PUTNAM, M.D.,
OF BUFFALO, NEW YORK.

I HAVE chosen this subject for presentation at this Congress because the symptoms and course of the disease present in these cases were to a great extent the same, but the interpretation of the symptoms from a pathological and etiological standpoint differed widely. In this series of cases I report two cases of Landry's paralysis with recovery, three cases of Landry's paralysis with death, one case of multiple neuritis, and one case of myasthenia gravis

CASE 1.—I was called in November, 1905, by the family physician to see a patient, a man, aged 30 years, with a previous history of having had an operation some years before for the removal of the coccyx. He had been in good health ever since but had always observed that there was some slight discharge from the region of the wound. When I saw him he was in bed with total flaccid paralysis of all the muscles of the lower extremities, the muscles of the trunk, and the muscles of the upper extremities. His respiration was laboured, the accessory muscles of respiration in the neck being strongly contracted with each effort of inspiration. The effort of swallowing was accompanied by marked choking and the attempt was given up. His temperature was normal, his pulse was 84, his reflexes were absent, his sensation was perfect, faradic contractility was present, and the diagnosis was made of Landry's acute ascending paralysis. As all treatment which has heretofore been tried in this disease has, as a rule, resulted in failure, I determined to give Credé's ointment of silver a fair trial. It was accordingly prescribed and it was rubbed into the spinal region night and morning until two ounces had been used. The only internal medication used was the fluid extract of ergot, one half-teaspoonful every three hours. The morning following my first visit the respiration was better, swallowing was more easy, and it was evident that the ascent of the disease had reached its limit. The further progress of the disease is best described by a gradual return of motion, first appearing in the distal muscles of the lower extremities and then involving the larger muscles. In two weeks motion had returned to all the muscles of the lower extremities and had begun to return to the muscles of the hand and forearm. In the third week contraction of the biceps was noticed. After six months the patient was walking and used his arms and hands with ease. At the time of writing the patient has no evidence of his previous disability with the exception of some atrophy of the muscles of the hand and an inability to stand upon his tip toes.

CASE 2.—I was called on Nov. 21st, 1905, by the family physician to see a little girl, aged four years, who had been in previously good health until the afternoon when she was suddenly stricken with paralysis of both lower extremities. So suddenly did the paralysis come on that the child, who was playing upon the floor a moment before, had in obedience to a call from her mother made an attempt to rise and found her legs were powerless. She was picked up, undressed, lagoons and marshes and possessing a large negro population. Ably seconded by his principal medical officer, Mr. W. H. W. Strachan, Sir William MacGregor commenced by instituting numerous public lectures on the subject, and by founding a ladies' league, the object of which was to reduce the large infantile mortality by quinine. At the same time he issued an order by which the prophylactic use of the drug was made compulsory for all public servants, and led the way by taking it with regularity himself. Efforts were then made to induce all the wealthier inhabitants to screen their houses, and most of the public buildings were shortly guarded in this manner, at least partially. Next, turning his attention to drainage-prophylaxis, he filled up marshes, and dealt with the shallow margins of lakes and lagoons in which the mosquitoes bred most readily. Similar measures were ordered along the line of railway into the interior, and when I visited the colony in 1901 I was a witness of the vigour and capacity with which the work was being conducted. Unfortunately his health now began to break down and his services were soon lost to the tropics, where his great knowledge and his warm enthusiasm for the high cause of sanitation had promised to do so much. At his departure that cause suffered a blow from which it has not yet recovered.[14]

---

[1] A paper read at the *International Congress of Psychiatry and Neurology* held at Amsterdam from Sept. 2nd to 7th, 1907.

Except in Lagos, little had yet been attempted in the other West African colonies, in spite of the surveys already mentioned. But when I revisited Sierra Leone in 1901 I was able to extend my tour not only to Lagos but also to the Gold Coast and to the Gambia, and to suggest in these latter colonies campaigns similar to that projected in Freetown. To start the work, in 1902 Dr. Taylor was sent to the Gold Coast[15] and Dr. Dutton to the Gambia,[16] so that in 1903 antimalaria measures were at least commenced in all these colonies; and I hoped that a few more years would witness the salvation of that rich but unhealthy land from the plague which had so long oppressed it. I may add that in 1904, by the generosity of King Leopold, Dr. Dutton and Dr. J. L. Todd were sent to the Congo Free State to investigate and to advise there also.[17]

Unfortunately, I cannot say definitely how far our hopes have been realised. The official reports and figures[18] are not sufficiently exact and copious to enable us to judge with certainty either regarding the measures which have been taken by local Governments or of the results, if any, which have followed. It is stated[19] that malaria fever has decreased among the British troops in West Africa during 1905. The admission-rate was only 59 per cent., against 84 per cent. in 1904 and an average of 139 per cent. for the eight preceding years; and the senior medical officer remarks that the improvement is "attributed to the antimalaria measures adopted during the last three years." But it is characteristic of these very incomplete publications that we cannot even ascertain where exactly the troops were stationed. On the other hand, we hear frequently from merchants and travellers in West Africa that the general health of Europeans has greatly improved, as shown by the decrease of death and invaliding among employees, miners, &c. For example, there has been a remarkable change, to judge from statistics kindly furnished to me by Mr. F. Shelford, in the health of men working on the Lagos railway. In the past it frequently happened that the percentage of days spent on the sick list by men employed on railway construction in West Africa was as high as even 10 or more per cent. During 1905 and 1906, however, the figure has been down as low as 1·12 per cent. and was always under 2 per cent. (on the "extensions").

III.—CAMPAIGN AT ISMAILIA.

Let us now proceed to consider more decisive campaigns elsewhere. But first let me refer to that great scientific discovery which gave so much indirect assistance to the prevention of malaria—the discovery of Finlay, Carter, Reed, Carrol, Lazear, Agramonte, Ross, and others, that yellow fever also is carried by mosquitoes. It is true that, though both diseases are mosquito-borne, their prophylaxis is widely different owing to the different habits of the stegomyia and the anophelines, to the rapidity of immunity in yellow fever, and to its resistance to quinine. Nevertheless, the case of the one helped the case of the other. No sooner was the stegomyia definitely incriminated at the end of 1900 than the American Government of Cuba, under General Leonard Wood, himself a medical man, set to work with a promptitude, energy, and intelligence not always visible in other Governments to use the facts which science had just placed in their hands. Except for a slight recent recrudescence, which we hope will shortly be conquered, the disease was practically swept out of the island from that date. This event occurred in 1901, just at the time when Dr. Taylor and myself were commencing our attempts at Sierra Leone. Owing to the examples so set similar campaigns now began to be started in various parts of the world. Perhaps the most classical and brilliant one was that of Ismailia commenced in 1902, which gave a complete and perfect demonstration of the possibility of banishing malaria and mosquitoes together.

The town of Ismailia was founded by the great Ferdinand de Lesseps in 1862 at a little distance from the middle point of the Suez Canal and close to the Salt Lake, Timsa. Though built in the midst of the desert, which surrounds it everywhere with its ridges of white sand like the undulations of a vast snowfield, it has nevertheless now grown to contain about 6000 inhabitants, most of whom are employees of the Suez Canal Company. Supplied with fresh water by means of a canal from the Nile, it possesses many good houses, gardens, and well-appointed streets, kept in admirable order by the officials of the company under the able and energetic President, Prince Auguste d'Arenberg, who himself resides here for many months every year. Immediately after the construction of the freshwater canal in 1877 malaria appeared for the first time in the town, which had been previously noted for its salubrity. The cases gradually increased in number until in 1886 almost all the inhabitants suffered from fever. In 1901 the President, having recognised the new discoveries, determined to employ them against this troublesome epidemic and commenced by sending a member of his highly competent medical staff, Dr. A. Pressat, to Italy to study the subject. Early next year, however, shortly after the commencement of the operations at Freetown, he invited me to go to Ismailia to advise upon the best means of attacking the disease. I arrived there in September, 1902, with Sir William MacGregor, who did me the honour to accompany me, and with Dr. Pressat on his return from Italy.[20] On our arrival we found all the officials of the company keenly alive to the importance of the work. They had already detected the anophelines in the town, had urged the general employment of mosquito nets, and had commenced an active quinine prophylaxis. On the other hand, the town was still swarming with mosquitoes. Even in the house of the President, where we were lodged, there were multitudes of culex, which we showed were being bred in the well-constructed cesspit under the house; while abundance of anophelines were found in the houses of the employees and were evidently carrying the disease everywhere in spite of the mosquito nets and the segregation of the Europeans. I felt, therefore, that here, as in other places where I had studied the subject, we should have to introduce the radical method of mosquito reduction if we wished for complete results, and I reported strongly in favour of this course. As Dr. Pressat has said, we formed "the conviction that we should establish for Ismailia a plan of campaign sensibly different from that which we had seen followed in Italy, where the campaign against mosquitoes occupied only a secondary rank—so that this destruction appeared to us to be the capital article of our programme" ([21], p. 130). We found the larvæ of the anophelines at once in various collections of water, principally in some small brackish marshes in the sand and some waters of irrigation, but happily not in the main freshwater canal, where small fish destroyed them. The campaign, conducted with intelligence and energy, presented no great difficulty. The marshes were filled up with sand, the irrigation channels were deepened or treated with oil, while the cesspits were soon rendered uninhabitable for the larvæ of culex. As Dr.

be positive that it was not a case of acute bulbar paralysis, but because of the rapid recovery under the rest cure, with massage, faradic electricity, and large doses of strychnine, I have considered this case as one of myasthenia gravis.

In this series of seven cases the patients had many symptoms in common but they must be separated into different classes. The diagnosis of Landry's paralysis should be made in those cases in which the onset was sudden, in which the muscular paralysis passes from the lower extremities to the upper extremities, in which sensation is unimpaired, in which the nerve trunks are not tender, in which the bladder and rectum are not involved, and in which the electrical reaction is unchanged.

The diagnosis of acute infectious multiple neuritis was made in those cases in which there had been a previous disease, as in the case of paralysis following urethritis, in which the symptoms are general motor paralysis, disturbances of sensation, tenderness of the nerve trunks, atrophy, and change in the electrical reaction. I do not believe that it is always possible to make a positive differential diagnosis between cases of Landry's paralysis and acute infectious multiple neuritis, nor between myasthenia gravis and acute bulbar paralysis. It is only by the reporting of carefully studied cases, however, that we can hope some time to improve our classification.

Medical Societies.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Sept. 5th, Mr. H. H. Taylor, the new President, being in the chair.—The President showed a man with a Rodent Ulcer on the Eyelid.—Dr. C. F. Bailey showed radiographs of a Small Stone in the Kidney and also the stone after removal; also radiographs of an Unusual Deformity of the Hands, thought by him to be due to rheumatoid arthritis.—Dr. Walter Broadbent showed a Baby with only Two Toes on the Right Foot and an Angular Bend in the Tibia, possibly due to intra-uterine fracture.—The President read his inaugural address on "The Milk Supply." He said that, considering that milk should form the staple food of all children, too much attention could not be paid to the manner of its production and distribution. Children born healthy could nearly always be brought up to be strong men and women if properly nourished. The Inspector-General for Recruiting remarked on the deterioration of the working classes, about 30 per cent. of recruits having to be rejected as below the standard required; though that was a low one. Though great improvements had been made in housing, water-supply, and food generally, no improvements had been made in the milk-supply. In the ordinary cowshed the floor and walls were covered with dung, the udders of the cows were filthy, and the cans were often washed in well-water not thought good enough for drinking. The milk often stood for hours in a hot dusty station, and when it reached the town it was retailed to milk-sellers to hawk about the streets, and finally reached the houses full of every kind of germ and contamination. Preservatives ought not to be allowed, as they enabled stale milk to be sold as fresh. Adulteration was on the increase owing to the low standard of fat required by law. No reform would come among the farmers unless the public, by buying only from the cleaner farms, compelled them through their pockets, and the medical profession should instruct the public. Inspectors of cattle should be appointed by the Government and not by the local authority, since often the worst delinquents were county councillors who would find a means of dismissing any inspector who found fault with their cattle. It was possible that human tuberculosis was a modified form of bovine, and the slaughter of all tuberculous cattle would decrease the incidence of tuberculosis in man. He thought that the giving of certificates to approved dairies by the sanitary authorities of towns was a method which promised to promote improvement. In conclusion he proposed the following motion :—

> That the Brighton and Sussex Medico Chirurgical Society views with grave concern the deplorable condition of the milk industry in this country, and urges upon the Local Government Board the prime importance of introducing into Parliament at an early date a wide and comprehensive measure for its reform.

—This was carried unanimously and it was forwarded to the President of the Local Government Board.

Reviews and Notices of Books.

Diseases of the Lungs. By ROBERT H. BABCOCK, A.M., M.D., until recently Professor of Clinical Medicine and Diseases of the Chest, College of Physicians and Surgeons, Chicago. London: Sidney Appleton. 1907. Pp. 809. Price 25*s*.

THIS work on Diseases of the Lungs is "designed to be a practical presentation of the subject for the use of students and practitioners of medicine" and a careful perusal has assured us that the author has admirably succeeded in the task which he has set before him. Dr. Babcock explains in his preface that "the original contract between the publishers and the author called for a work of one volume which in approximately 1000 pages should cover the entire field of diseases of the chest." It was found, however, that such an arrangement would prove unsatisfactory, since it would necessitate too great a condensation to make the work of practical value. Consequently, the portion dealing with diseases of the heart and the arterial system was published in 1903 and we now have before us the second portion entitled as above.

The first chapter deals with bronchitis and in conformity with the general scheme of the work etiology, diagnosis, and treatment receive especially full and practical consideration. The remarks on the etiology of the disease are especially worthy of notice. A separate chapter is devoted to the discussion of pulmonary hæmorrhage. For the treatment of copious hæmoptysis Dr. Babcock speaks highly of the subcutaneous injection of $\frac{1}{50}$th or even $\frac{1}{25}$th of a grain of sulphate of atropine. Its effect is the speedy dilatation of the superficial capillaries, as shown by the redness of the skin throughout the body, and hence "the remedy bleeds the patient into his own vessels as it were." This is a logical method of treatment. A similar effect is produced by the inhalation of nitrite of amyl. Dr. Babcock does not mention this drug in this connexion but its administration in cases of hæmoptysis has yielded satisfactory results. We fully agree with Dr. Babcock's remarks on the use of ergot in pulmonary hæmorrhage; he is of opinion that notwithstanding its popularity it is not only irrational for bleeding due to erosion or rupture of a pulmonary artery but it is capable of doing harm. Ergot raises the blood pressure in the aortic system by contraction of the arterioles through stimulation of the vaso-motor nerves. Whether indirectly through its action on the aortic system or directly on the pulmonary vessels, ergot, therefore, raises the blood pressure in the lungs and defeats the purpose intended. Dr. Babcock realises that this drug is, and frequently has been, given for the relief of hæmoptysis and apparently with beneficial results, but he believes (and in this opinion we are in perfect accord) that it is in reality a matter of *post hoc*, not *propter hoc*. In other words, that if bleeding has ceased after the administration of ergot it has been in spite of, and not on account of, the drug. Another objection to this drug lies in the gastric disturbance which it so frequently creates. In concluding this subject Dr. Babcock speaks with no uncertain voice but he will doubtless be supported by a large number of physicians when he says: "From every standpoint, therefore, I feel compelled to raise my voice in protest against the use of this agent in cases of hæmoptysis."

No less than five chapters are devoted to the consideration of acute fibrinous pneumonia and these will well repay careful study. In discussing the etiology of the disease the influence of cold is duly dealt with. Dr. Babcock is of opinion that a sudden or prolonged chilling of the body cannot of itself produce pneumonia but it serves as the trauma which prepares the way for the subsequent action of

5.—Sick Certificates and Sick Leave Granted to Government Employees.

(Numbering 176 in 1901 and 281 in 1904.)

Years	1901	1902	1903	1904	1905
Certificates	236	40	23	14	4
Days of leave	1026	193	73	71	30

To these figures Dr. Watson adds[27] that so great has been the reduction of the malaria that he has lost a large part of his private practice as District Medical Officer. Regarding the reduction of mosquitoes he remarks[27]: "A definite improvement in the health of Klang was evident when only the swamps nearest to the main groups of houses had been dealt with, and while other swamps within the town were still untouched. The mosquitoes from these did not appear to travel any distance, and there has been no evidence of dangerous immigration of anophelines from the extensive breeding-places which, until the middle of 1904, existed just outside the town boundary, and some of which still remain. Yet the species breeding in these swamps were identical with those breeding within the town."

The objection raised against the campaign at Ismailia—namely, that it possesses a dry soil and climate—cannot be raised against the well-conducted campaigns in the Federated Malay States, and the world owes a debt of gratitude to the Government of these States, to Mr. Travers, and especially to Dr. Watson, for the fine example which they have set.

V.—CAMPAIGN AT HONG-KONG.

One of the earliest and best of the campaigns in British territory. The city of Victoria, usually called Hong-Kong, runs for nearly five miles along the north of the island of that name at the mouth of the Canton river in South-East China. The island, 11 miles long and from two to five miles broad, consists of a broken ridge of hills, rising to nearly 2000 feet, and the city is built on a hill sloping down to the water, some of the terraces and houses being 500 feet above sea level. There is also a large residential district on the mountains reached by a cable tramway. The soil is granitic. All along the face of the hill on which Victoria is built there are beds of streams, known as "nullas," which used to swarm with anopheline larvæ. The population of the colony was 377,850 in 1905, of which 10,835 were whites (nearly half belonging to the British army and navy). The rainfall is from 70 to 80 inches a year. Malaria has been always very prevalent here, and I remember that in 1881 the colony was cited as an example of the telluric miasma due to decaying granite. The first researches on the new lines were commenced as early as May, 1901, by Dr. J. C. Thomson,[29] who undertook an exhaustive study of the mosquitoes and their breeding-places. He examined over 32,000 specimens, of which he found about 4 per cent. to be anophelines, and in November advised an active antimalaria campaign by drainage, clearing of jungle, "training" of the nullas, the use of wire gauze, oiling pools, and quinine prophylaxis. As seen by his excellent papers,[30] his recommendations were not of a general nature, but were particular, practical, and exact. These recommendations were rapidly acted upon by the Government. Since 1901 all the nullas or water-courses within and near the city were "trained"—that is, rendered so smooth and even that the anophelines could no longer breed in them; and much similar work was done wherever most needed elsewhere by training water-courses, buying up rice fields, and so on. The details of the campaign are so numerous that it is impossible to give them here. They will be found in the publications given in the bibliography and in a good paper by Mr. J. M. Young,[31] who took part in the early stages of the work. The results are given in the annual sanitary reports of the colony and in a recent address by the medical officer of health, Dr. W. Francis Clark.[32] Dr. Thomson informs me that before estimating them it is necessary to remember that malaria can never become extinct in Hong-Kong owing to the fact that some 3000 to 4000 natives come and go from and to the country districts every day, and that a number of these will remain infected in spite of all local measures. Nevertheless the figures show a rapid diminution both in the admission and in the death-rates.

Deaths in city (Chinese only)	290	302	250	218	242	281	189	152	93	87

The official sanitary reports give similar figures. The improvements have, of course, varied much in different localities. Thus in 1900 the western end of Bonham road used to be one of the worst districts. Now in 1905 it is reported not to have sent a single case to the Government Civil Hospital.[33]

With regard to cost, Dr. Clark reports that up to the end of 1905 the Government had expended about £5000 on antimalaria measures, and estimates that £6500 would be spent by the end of 1906—a small amount to pay for the good that has been done. The campaign in such a thickly populated district must be difficult. A larger expenditure would probably have produced still more marked results and it would have been useful to estimate the endemic index in various parts of the area. I am much indebted to Dr. Thomson and also to Mr. J. Bell for the detailed information which they have been so kind as to send me but which I have no space to give more fully.

VI.—CAMPAIGNS IN INDIA.

In 1898 I had hoped that India would have led the way in the matter of malaria prevention. Long previously the Government had done very well by issuing cheap quinine in malarious localities and by making several local inquiries. The disease existed more or less throughout the country and in some military stations caused an admission-rate of several thousands per mille, while in other places it was an extremely serious detriment to development. There were numbers of places as dry and easy to deal with as Ismailia, while few presented worse difficulties than the towns in the Malay States. The military stations were under the complete control of the authorities, and experienced administrators, sanitary officers, and engineers abounded everywhere. So far as I can ascertain, however, little or nothing was done for several years. The first active campaign seems to have been inaugurated in 1902 as an experiment at Mian Mir in the Punjab, but was most unfortunately a failure, at least at first.

Mian Mir.—This is a large cantonment or garrison town situated on the flat and hot plains near Lahore. Constructed in 1851–52 in the midst of what was then an arid and treeless desert, it was later well watered by irrigation canals. The result was that malaria began to prevail to such an extent that in 1879 the annual admission-rate for fevers rose to 3427 per 1000 of the troops and the place was called "the white man's grave." In 1901, however, Dr. Stephens and Captain Christophers of the Malaria Commission of the Royal Society were sent on my suggestion to India and investigated the mosquitoes of Mian Mir amongst other places.[34] In April, 1902, practical operations were commenced, evidently on the Sierra Leone model, by Captain S. P. James, I.M.S., and afterwards by Captain Christophers. The results, however, were not only negative but were stated in such a way by these observers as to suggest that mosquito reduction was generally a difficult if not impossible task.[35]

ingredients manufacturers would be forced to give way and to direct their energies to the supply of foods to which no objection could be taken either in regard to their description or to their particular mode of preservation. As the author says in his preface, honest and truthful practices of manufacture and labelling are to be promoted in every possible manner and in the end the true, the ethical, and the just in these practices will prevail.

The book before us covers a good deal of the ground but not all. We may anticipate, however, that the cordial reception which it is sure to receive will induce the author to proceed further. For the present we must be content with the foods now dealt with. After a chapter of generalisations Dr. Wiley proceeds to the consideration of meats and meat products. In this section he deals with the preparation of animals prior to slaughter, the composition of various kinds of flesh, the preservation of meats, the value of meat extracts, and so on. He refers to yeast extract as an adulterant of meat extract but apparently does not seem to be acquainted with a better method of determining yeast extract than that which depends upon the production of turbidity when zinc sulphate is added to a strong solution of meat extract containing yeast extract. In Part 2 we come to a consideration of poultry, eggs, and game birds, which is necessarily a short section. This is followed by a more important part dealing with fish foods, in which the composition of the edible portion of various fishes, including shell-fish and turtle, is given. Next he proceeds to discuss milk and milk products and this section is succeeded by a chapter of special interest on cereal foods. We find here some noteworthy observations on the effect of modern milling methods on corn products. These methods of preparing the flour, although so common, are not, the author says, to be preferred either by reason of palatability or nutritive properties of the products. The old-fashioned milling process, he adds, makes a more palatable and more nutritious diet and affords a higher degree of heat and energy. In regard to proprietary breakfast foods he says what we believe to be true, that people of limited means can be safely advised on the score of economy, palatability, and nutrition to prepare their own cereals for ordinary breakfast purposes. Then follows a section on vegetable condiments and fruits, which in its turn is succeeded by a section on vegetable oils, fats, and nuts.

It will be gathered that the book is designed not so much for the use of the analyst as for those readers who desire to have a knowledge of the value of foods. Nowadays, when such extravagant claims are made in favour of so many widely advertised foods, it is important that the public should have some knowledge of the composition of food and of the individual value of its constituents. Dr. Wiley has written his book with the excellent object of instructing the public and manufacturers on these points, and we are bound to say that he has presented his facts, both chemical and physiological, in a way which should be easily "understanded of the people." Common sense is written on every page. The following is a specimen taken from the introductory chapter. "We are all familiar," he says, "with the advertisements of foods to feed the brain or the nerves or the skin. It is hardly necessary to call attention to the absurdity of claims of this kind. One part of the body cannot be nourished if the other parts are neglected, and the true principle of nutrition requires a uniform and equal development and nourishment of all the tissues. It is true that many of the tissues have predominant constituents. For instance, in the bones are found large quantities of phosphate of calcium and in the muscles nitrogenous tissues dominate. In the brain and nerves there are considerable quantities of organic phosphorus. All of these bodies, however, are contained in normal food properly balanced." We can commend heartily Dr. Wiley's recent work and hope that he will pursue the subject further and will give us his views on malt liquors, wines, and spirits.

LIBRARY TABLE.

Some of the Clinical Aspects of Pneumonia. By DONALD W. C. HOOD, C.V.O., M.D. Cantab., F.R.C.P. Lond. London: John Bale, Sons, and Danielsson, Limited. 1907. Pp. 117. Price 7*s.* 6*d.* net.—This book is largely a reprint of clinical lectures and demonstrations delivered at the West London Hospital, to the post-graduates attending the practice of the hospital, and as might be expected from this circumstance it is severely practical in character. Most of the numerous difficulties of diagnosis, prognosis, and treatment that may beset the general practitioner in dealing with the varied symptoms to which the name pneumonia is applied receive attention, and in many cases Dr. Hood gives illustrations from his hospital or private practice in support of his pathological teaching and therapeutic recommendations. He considers that the treatment of pneumonia resolves itself largely into the management of a patient suffering from the effects of a poison attacking a vital organ, and that this essentially toxic condition demands for its treatment an abundance of pure fresh air, dietetic treatment, and a few drugs when simple diaphoresis, tonic support, or purgation is required, among which he finds a place for alcohol. He is absolutely opposed to the use of the powerful synthetic remedies, preferring to trust to tepid sponging in pyrexia, with, perhaps, the assistance of quinine or alcohol. The general practitioner, especially the recently qualified man, will find this a very valuable little book, but the price demanded for it is surely somewhat high.

Invertebrate Zoology. By G. A. DREW, Ph.D. London: W. B. Saunders Company. 1907. Pp. 201. Price 5*s.* net.—This little manual has for its basis a set of laboratory directions prepared by a staff of instructors to meet the needs of the students at the zoological classes at the Marine Biological Laboratory at Woods Holl, Massachusetts. The author rightly suggests that few instructors will find it desirable at their own classes to compel their students to follow the whole procedure proposed in any handbook. Every teacher must exercise his individuality and the average needs of every class vary in detail, but we consider Dr. Drew's manual to be a particularly useful little work, for it is not only arranged in an orderly manner but the salient points are given proper prominence, so that the time of teacher and taught alike would be economised by following out the plan laid down.

The Midwives' Pocket Register and Case book. By R. J. BLACKHAM, L.R.C.P. Edin., L.M. Dub., D.P.H. Lond., Major, R.A.M.C. London: Henry Kimpton. 1907. Pp. 29 and tables.—This little volume has been prepared to provide practising midwives with a convenient substitute for the bulky official register. As Major Blackham points out in a prefatory note, midwives in practice are required to keep a register of cases, but the official book issued for the purpose measures 13 inches by 8 inches, dimensions which make it not easily portable. The Pocket Register, the dimensions of which are 5½ inches by 4 inches, provides space for keeping a complete record of the labour and puerperium of 50 cases, a number which is probably in excess of the average attended by a midwife in a year's ordinary practice. The little book also includes the rules laid down by the Central Midwives Board for regulating the practice of midwives, to which rules some valuable practical notes have been added by the author, together with some brief remarks on the care of infants arranged in the form of a decalogue which it is suggested that the mother might well learn during the enforced leisure of the latter days of her puerperium.

the flat ground and used to breed many mosquitoes. All ese waters were attacked by various methods, with the ult that the larvæ were found in quickly decreasing mbers: Now, in his second report, Dr. Balfour remarks at, although mosquitoes have not been completely nished, yet "we are rid, and well rid, of the annoying gomyia, the dangerous pyretophorus is kept in abeyance, d culex, the ubiquitous, has ceased to be a nuisance." adds: "I have not seen a living, wild, adult anopheline Khartoum for more than a year and a half, and I am ways on the outlook for these insects." The effect on the ount of malaria could not be estimated owing to the sence of statistics and to the fact that malaria was never ry prevalent there. If by accident the insects are owed to recur, malaria reappears; and he tells me at since the date of his second report six primary ses have been caused in this way, though the outbreak s promptly suppressed. Owing to the assistance of lonel R. H. Penton, R.A.M.C., principal medical officer the Sudan, the work was extended. Surrounding villages e heavily infected, but excellent rules regarding irrigation e being introduced. Dr. Balfour and his colleagues are to warmly congratulated on their work.

Some years ago Colonel Penton asked me to go to the dan to advise regarding the prevention of malaria in the dan. I was unfortunately unable to accept the invitaon, but he himself has carried out excellent work with nsiderable success in Kassala and El Obeid, besides hartoum.[42] In Port Said (56,000 inhabitants) an active mpaign has been conducted by my brother Mr. E. H. oss against the mosquitoes there.[43] The result is, he says a letter dated last March, that there "has been almost mplete absence of the pest in a year's work. No case of ute malaria has been admitted to hospital since August st. There has been a reduction in the death-rate. ...... At smailia the results are well known. There is now a comlete absence of mosquitoes and of malaria. But in some f the villages round there is much malaria and many nophelines, owing to the irrigation." In Cairo, in the istrict of Kasr-el-du-Barra, and Helowan, campaigns have een organised with success by my brother Mr. H. C. Ross. his Egyptian work has been carried out with the sanction nd approval of Sir Horace H. Pinching, the distinguished ead of the Sanitary Department of Egypt.

Candia, Crete.—The accounts of this excellent campaign, onducted in connexion with the British troops in Crete, vill be found in successive numbers of the *Journal of the Royal Army Medical Corps*. The town of Candia, conaining 21,000 inhabitants, is situated on the seashore of a emicircular plain bounded by hills. The rainfall is heavy nd the ground is traversed by many streams which become orrents in winter and nearly dry in summer. Two of them ave marshy margins near the sea. The houses of the town re of the Oriental type and contain many wells. The troops re accommodated in quarters to the west of the town and lose to it and suffered considerably from malaria. Apparently as early as 1902[44] Lieutenant-Colonel J. V. Salvage, R.A.M.C., commenced to examine into the distribution of anophelines and to destroy the larvæ by drainage, or by closing or oiling the wells, or putting fish into them, and expressed himself hopefully regarding the result. In March, 1903, Major C. J. MacDonald arrived in Crete and continued the work.[45] He gives many very interesting details. Works of a permanent nature were attempted and quinine prophylaxis and mosquito nets insisted upon. The first results were as below:—

Years	1901	1902	1903
Strength	564	460	410
Admissions	1540	1034	227
Rate per cent.	273	236	55

The admissions include simple continued fever, together with malaria, in order to avoid error due to diagnosis. Major MacDonald attributes the fall to the measures taken. In 1905, Captain R. A. Cunningham, R.A.M.C., adds a third article,[46] in which he states that the fall in the malaria-rate had continued, and was only 30 per cent. in 1904 compared with the 55 per cent. of 1903. The mosquitoes were so few that it was almost unnecessary to use a net at night. In 1905 (18, p. 103) there were 246 admissions, or a rate of 38·7 per cent. Many men become infected on guards and outposts.

St. Lucia.—A good account of this work has been given by Colonel F. P. Nichols, R.A.M.C.[47] British troops have long been stationed at Castries, St. Lucia. During 1902 and 1903 drainage works were carried out by Colonel Hodder of the Royal Engineers, but shortly afterwards the garrison was removed. Colonel Nichols has attempted to ascertain the effect of the operations on the health of the troops before they departed. He gives many interesting cases, and remarks: "The apparent effects were very marked, as noted by both officers and men, by Major Bent, R.A.M.C. (to whom I am indebted for many notes on the point), and by the other Royal Army Medical Corps officers, and as testified by the immediate drop in the admission-rate for malarial fevers, which began at once and has continued ever since." Colonel Hodder said: "At the present time (1904), in buildings which were formerly infested with mosquitoes of all kinds, scarcely a sign of one exists; but it has taken two years of continuous work to effect this result." Colonel Nichols gives and discusses many figures from among which I select the following:—

Years.	Admission-rate per cent.	Years.	Admission-rate per cent.
1895	339	1901	575
1896	417	1902	851
1897	314	1903	127
1893	256	1904	77
1899	141	1905	45
1900	100		

The admissions include simple continued fever.

VIII.—CAMPAIGNS AT HAVANA AND PANAMA.

Havana.—I have already referred to the great discovery of the mode of propagation of yellow fever and the subsequent campaign against that disease started in Havana in February, 1901. The result as regards yellow fever was decisive for several years, and although it reappeared in 1905 and 1906 it was again banished when the United States resumed control of the island last year. As regards malaria the general war against mosquitoes in Havana produced marked effects. Almost immediately after the commencement of the operations in February, 1901, this disease also began to decline, and the diminution has been steadily maintained. The details will be found in the full monthly statistics of the Board of Health,[48] but Dr. Charles Finlay, the distinguished originator of the mosquito theory of yellow fever, and head of the Health Department of Cuba, has kindly furnished me with the following figures of the deaths from malaria in Havana for a number of years:—

Years	Deaths (malaria).	Years.	Deaths (malaria).	Years.	Deaths (malaria).
1880	335	1889	228	1898	1907
1881	223	1890	170	1899	909
1882	191	1891	203	1900	344
1883	183	1892	202	1901	151
1884	196	1893	240	1902	77
1885	101	1894	201	1903	51
1886	135	1895	206	1904	44
1887	269	1896	450	1905	32
1888	218	1897	811	1906	26

The population of the city is about 250,000. Dr. Finlay tells me that it has been possible to carry out antimosquito work outside the city only occasionally when yellow fever or malaria threatened certain localities. On all such occasions a regular antimosquito campaign was started and ordered to be continued thereafter. This great work, due to Gorgas, Finlay, and the United States Government, constitutes an epoch in tropical sanitation.

Panama.—Perhaps even more remarkable is the work of the Americans under Colonel Gorgas on the canal zone of the Isthmus of Panama. As is well known, the attempt of the French to cut the canal through the isthmus was foiled principally by yellow fever and malaria, and I was told that their effort had cost quite 50,000 lives. The Americans took made her drawings illuminate his words. The picture of the night-jar, for example, shows very well the characteristic pose of the bird along the branch, the bark harmonising so truly with the ash-grey, brown, and bronzish markings of the plumage that the bird escapes notice effectually. Mr. Stonham's intimate acquaintance with his subject peeps out on every page, for there is hardly a bird on whose habits he has not some characteristic remark to make.

Matter and Intellect. By ANDREW ALLAN. London: A. Owen and Co. Pp. 224. Price 5*s.*—This is a little book the contents of which might be inferred from its claim to be a reconciliation of Science and the Bible, and might be more certainly deduced from its closing sentence: "I raise no altar to the Unknown God, for how can we worship That which we do not know? Yet there are only three things in this world in regard to which we possess positive, unquestionable, and first-hand knowledge. We know that the earth is beneath our feet—That is Matter: we know that the sun is shining—That is Energy; and we know that a stone unsupported falls to the ground—That is Law or Will. MATTER, ENERGY AND WILL—Three in One and One in Three—This is THE GREAT I AM." Those who think with the author will hardly need the book; those who do not hold his views, whether because their creed is more or less transcendental, are not in the least likely to be converted by the powers of argument which he displays.

Health in the Home Life. By HONNOR MORTEN. London: J. Clarke and Co. 1907. Pp. 170. Price 2*s.* 6*d.* net.—The obvious things are said in this book upon health in the home and upon what may be called domestic surgical and medical emergencies. There is no more originality shown in the directions given to the nurse than in those given to the public, but in her excursions into medicine Miss Morten occasionally tells us a thing or two of which we were in ignorance. The advice is given now and again "*to send for* the doctor," but it is difficult to gather exactly when, according to Miss Morten, domestic self-help should be relied upon and when expert assistance should be summoned. The necessity of calling in a surgeon is recognised in the treatment of hernia, fractures, and "convulsions," but the readers are apparently expected to be able to deal with the common dislocations, colic, "fits," and burns without professional aid. The information conveyed in the chapter on contagion and disinfection is too scrappy to be of much practical value and the author would appear to know more about schools for girls than schools for boys. We regret not to be able to give a warmer welcome to a book obviously written with the idea of raising the standard of health in the home by increasing the knowledge of the heads of households. The object is good and to some extent the book has done what is intended of it, but as a whole it is not successful.

The Great Eastern Railway Company's Tourist Guide to the Continent. By P. LINDLEY. 1907. Pp. 111. Price 6*d.*—The features of this practical little guide are an excellent series of continental maps and some useful particulars of new tours in Holland, in North and South Germany, and Belgium. The less known side valleys of the Rhine come in for interesting notice, while scraps of information, sometimes quite well illustrated by photograph or pencil, are given of such old Flemish towns as Ghent, Bruges, and Ypres. The object of this guide is to stimulate us to travel, and it can hardly fail to put its reader into the desired mood.

JOURNALS AND MAGAZINES.

The Haslemere Museum Gazette. By JONATHAN HUTCHINSON, F.R.C.S. Eng., LL.D., F.R.S., assisted by E. W. SWANTON, Curator of the Haslemere Museum. Vol. I. 1906–07. London: J. Bale, Sons, and Danielsson, Limited. Pp. 622. Price 7*s.* net.—This volume offers a perfect feast of objective education and field-study. The illustrations include portraits of Cobbett, Albert Durer, Charlotte Corday, and Fénélon; the ova of a lackey-moth on a twig; Kit's Coty House; a currant leaf infested with the fungus *Cronartium ribicolum;* a rook's head with a malformed bill; and the list might be greatly prolonged, every example showing the wide range of subjects which has fallen under the learned notice of Mr. Hutchinson, the conductor of the *Gazette.* The literary matter rivals the illustrations in diversity, the idea of the conductor being to encourage the formation in as many centres as possible of educational museums similar in scope and object to the one which he has founded at Haslemere, and the underlying aim being to stimulate the public to first-hand observation of all sorts. Among the special headings under which the contents of the *Gazette* are ranged are extracts from expository lectures delivered in the museum at Haslemere; descriptions of specimens and notes of field natural history, astronomy, and geology; and portraits, under which heading especial attention has been given to the history of race and the conditions which influence alike physiognomy and character. There are particularly interesting notes scattered throughout the *Gazette* upon plant pathology, a subject to which medical observers might perhaps turn their attention more minutely, for the similarity between certain of the morbid processes to be found in the vegetable kingdom and those prevalent in the animal kingdom seems to promise valuable information as the reward of research. We trust that the skill and energy displayed by Mr. Hutchinson and Mr. Swanton in compiling this interesting volume will be repaid by the securing of a large circulation and by the creation of a general movement in favour of the establishment of such museums as the one at Haslemere in many provincial centres. But where are the provincial centres to obtain the philosophers to act as honorary curators of their museums and honorary editors of their records? Haslemere has Mr. Hutchinson, and Mr. Hutchinson's knowledge of men and things is without parallel in range, while his willingness to diffuse that knowledge is unstinted. We do not suggest that all the local centres should await the arrival among them of a Jonathan Hutchinson, for that would be to condemn the movement for the establishment of local museums *ab initio,* but a local museum of observation cannot be started, we fear, without the benevolent autocracy of a learned and generous philosopher, while the blend of wisdom and altruism required is very scarce.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

SPERMINE (KALENICHENKO).

(AD SIEMSSEN, 3 AND 4, WATER-LANE, GREAT TOWER-STREET, LONDON, E.C.)

THIS extract is prepared in the laboratory Kalenichenko of Moscow under the personal supervision of medical men. It contains the peculiar principles of the extract of animal testicle and is regarded as a valuable therapeutical agent in the treatment of neurasthenia, impotence, and wasting diseases. More recently the extract has been used with, it is stated, good results in cases of diabetes mellitus. The fluid submitted to us was of a light sherry-like colour and is evidently an alcoholic extract, suitable flavouring agents being present also. Precautions are taken, it is said, to insure that the glands (bovine testes) are healthy. It would appear that in the preparation of this extract particular care is taken to obtain a pure and active material.

ridiculous to suppose, for example, that a large native population will use nets, or take quinine, or destroy mosquitoes, simply because the "doctors" advise them to do so. Even among civilised nations hundreds of thousands reject so simple a precaution as vaccination. In other words, from a sanitary point of view the general public is a child which must have everything done for it.

The second mistake is to suppose that small local authorities, if left to themselves, will interest themselves greatly in sanitation. A review of the campaigns against malaria which I have discussed will show that all of them are due to the energy and intelligence of single persons. If a locality possesses a governor or a medical man of capacity the campaign is started and is continued as long as he remains there. If not, nothing whatever is done. The truth is simply that local officials are, as a rule, unwilling to take the necessary trouble. Secure of their pay and their pensions they easily avoid the obligation by pretending that *the work is too difficult or too expensive*. Now the only way to overcome this inertia is to use official compulsion from the higher authorities. But, strange as it may seem, I have not known a single case in which such action has been taken. The local authorities are allowed to go their own way quite uncontrolled and are not even compelled to collect statistics At the same time nothing is done to encourage sanitary officials to bestir themselves in this line. I have not heard of a single instance in which anyone who has really done good work against malaria has received official thanks or reward for his pains; while, on the other hand, honours have been given to men who have actually retarded such work. There is often much pretence of action—conferences are held and speeches are made, but the years elapse and—the malaria remains as it was.

Besides local inertia there is another reason why local efforts against the disease are often so limited and that is the fact that medical men in the smaller colonies do not always possess the knowledge of how to use the colonial resources to the best effect. Ill-advised attempts are made and result only in failure, waste of money, and discouragement of other efforts.

X.—RECOMMENDATION.

After consideration, therefore, I can only suggest—what I have fruitlessly suggested many times for many years—that the best way *to encourage more vigorous action* in the future is to centralise the antimalarial administration. Each principal government which presides over malarious countries or colonies should appoint a special commissioner to travel from place to place in order (1) to advise local authorities as to the best measures for dealing with malaria in each locality; (2) to report to the head government; and (3) to organise the collection of statistics. Such an appointment is perfectly practicable and is in fact nothing but the specialisation of the Indian system of sanitary commissioners or of the American Marine Medical Service system. It would gather the reins of antimalarial organisation into one hand; would help the willing authorities and stimulate the unwilling; and would save funds now often wasted on abortive efforts. At present, I think, the inhabitants of many malarious places have reasons to make serious complaint of the slackness with which modern discoveries have been followed up, and we can only hope that the next decade will show a more rapid advance in this respect.

ADDENDA.

Since the above was written the colonial reports[16] for some West African colonies for 1906 have been published and give more detail on sanitary matters than previous reports have afforded. In Sierra Leone the sum of £2223 was expended on repairs to streets and on laying down concrete surface drains, and a scheme "for devising *a proper system* of drainage has been approved by the Secretary of State and will be carried out during the current year." The mortality and morbidity returns as briefly given in the report show no marked change during recent years. For Bathurst, British Gambia, it is stated that, "Bordered as it is on two sides by large swamps, there must, however, be a *great deal of fever* endemic in the place, and this it is impossible to prevent, though considerable improvement has been effected by the anti-mosquito sanitation measures which are vigorously prosecuted." In the report for the Gold Coast it is stated that "improvements were carried out at considerable expense in the towns of Cape Coast, Sekondi, and Kumasi." The deputy principal medical officer states: "I have no hesitation in saying that the health has improved," but I can find little trustworthy evidence of this in such figures as are given in the colonial report. Work done in Burma has already been mentioned but further details will be found in Colonel King's report on the sanitary administration of Burma for the year 1906, showing that active interest is now being taken in the matter.

Regarding the Federated Malay States, there was a great increase of malaria during 1906 in the district surrounding Klang and Port Swettenham, owing to a large influx of coolies, but in these towns themselves it has remained absent owing to the measures taken (supplement to the *Selangor Government Gazette*, 1907). Dr. M. Watson is urging energetic measures for dealing with the malaria of coolies in plantations Great interest is shown in the country regarding the whole subject, and the medical department is happy in having the strong support of the British Resident, Mr. Conway Belfield.

At the meeting of the British Medical Association in July Major A. H. Nott, I.M.S., described an antimosquito campaign at Murshedabad in India, but I regret that I have not yet been able to see a copy of his work.

Owing to the efforts of Colonel Seely, M.P., and Mr. Hahnemann Stuart, the British Colonial Office promised last year to issue a report on the prevention of malaria in all the colonies in its jurisdiction, but the paper has not yet been *published*.

As many shipowners have taken interest in tropical medicine I sent a circular some months ago to most of the leading firms with sailings to the tropics asking them for information regarding the steps which any of them may have taken to prevent malaria on board their ships. Although the request was repeated only three firms have replied. The Booth Steamship Company (Liverpool, New York, and Brazil), which has done much for research work, informs me that quinine is given regularly to its crews while on the Amazon, and that the men are provided with mosquito nets and the ships' hospitals with wire-gauze fittings. They have few cases of fever. The Harrison Line (Liverpool, America, South Africa, and India) has never had many cases of fever on board its ships; but nevertheless quinine is given regularly "at malarious ports," and the men are supplied with muslin mosquito-bars. Messrs. John Holt and Co., who charter steamers to various tropical ports, *strictly order the use of quinine* and *provide* mosquito nets and sun-helmets for the men. Mr. Holt says that "the general effect of our instructions has been to lessen fever arising from malaria," but is disappointed that it has not been entirely banished. He is not a shipowner, but wishes that some owner would build (experimentally) a steamer fitted for excluding mosquitoes, and cannot conceive that such a thing is impossible to human ingenuity. He thinks that legislation should be passed to compel vessels visiting the tropics to adopt the necessary measures against malaria.

Liverpool.

A NEW OPERATION FOR PENILE HYPOSPADIAS.

BY RUPERT T. H. BUCKNALL, M.S., M.D. LOND., F.R.C.S. ENG.,

ASSISTANT PROFESSOR OF CLINICAL SURGERY AT UNIVERSITY COLLEGE, LONDON, ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL, SURGEON TO IN-PATIENTS AT THE VICTORIA HOSPITAL FOR SICK CHILDREN, CHELSEA.

THE following operation for the relief of penile hypospadias has not, as far as I am aware, been previously described. It has proved so successful, however, in the few cases in which I have tried it that I now venture to give an account of it, as I believe that in suitable cases it will be found to afford more satisfactory results than can be obtained by the various operative procedures now in vogue.

Description of the operation.—The penis is drawn up over the abdomen in the middle line and the scrotum is drawn down in the opposite direction between the thighs, so that the groove, usually present in such cases, on the under surface of the penis, the false meatus urinarius, and the scrotal raphé all occupy the median line (Fig. 1). Two similar incisions are now made on each side of the median line one eighth of an inch from it and parallel to it. Each begins on the glans penis and is continued down the penis until opposite the misplaced urethra at its root. Each incision is now prolonged on to the front of the scrotum on each side of the

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 28, 1907.

Medical Practitioners and Medical Referees under the Workmen's Compensation Act, 1906: The Legal Position.

WE published last week a letter from Mr. A. BENTHALL who refers with approval to the regulations issued under the Workmen's Compensation Act, 1906, on the ground that they authorise the attendance of a medical practitioner on behalf of those whose cases under the Act are submitted, on dispute arising, to medical referees. The class of cases referred to is that in which a workman has been suspended or has claimed from a certifying surgeon a certificate of disablement in order to entitle himself to the benefits of the Act. The reference to the medical referee is to be ordered by the registrar of the county court on the application of the employer or of the workman when one or the other is aggrieved by the granting or the refusal of such a certificate. The medical man, therefore, who, according to our correspondent, will be able to appear before the medical referee and, so to speak, to make good his view of the patient's case on behalf of the employer or of the patient will be one who has examined the workman on behalf of the employer or who has treated him as his medical attendant. Possibly it is intended to be suggested that the certifying surgeon also may be present, as he too presumably would be interested in seeing his certificate upheld and in defending it. We can quite well understand that a medical man who has attended a workman or who has examined him on behalf of an employer should desire to be present in order that his opinion as to the case and as to the matters which he has observed should be fully considered by the medical referee, and it is from the point of view of the practitioner so situated that our correspondent has written. With regard to the certifying surgeon, we are inclined to doubt whether he would often have the time or the inclination to attend gratuitously *even in order to defend his* decision, and to do so would be inconsistent with his position. He is himself an independent judge whose decision has been appealed against.

With regard to the medical referee, the matter may to some extent be left to his discretion, but we are inclined to think that he will prefer to check personally and without assistance matters of observation recorded by others and submitted to him in writing. The question whether the presence of other medical men is desirable or not is no doubt one which may fairly give rise to discussion, but we are disposed to doubt whether the regulations are as clear in allowing it as is argued by Mr. BENTHALL. The regulations prescribe in detail the formalities to be observed by the employer or the workman accordi to their respective circumstances when aggrieved by t decision of a certifying surgeon. Those material to t question which we are discussing are as follows:—

9 (*a*). Any application under the foregoing regulatio shall be made in writing and shall state the grounds which the reference is asked for in accordance with the for prescribed in the schedule to these regulations, or as ne thereto as may be. (*b*) The application shall be accon panied by the certificate, or a copy of the certificate, obtaine from the surgeon by whose action the applicant is aggrieve and by any available report or reports of any medical pract tioner by whom the workman has been examined; and if th applicant is an employer by the notice of disablement suspension served on him by the workman, and by an unde taking to pay any reasonable travelling expenses incurred the workman in attending for examination by the medic referee. (*c*) The applicant shall also file with the registra such copies of the application and other documents as afor said as may be necessary for the use of the medical refere and of the employer or workman, as the case may be hereinafter referred to as the respondent, who, together wit the applicant, is directly interested in the application.

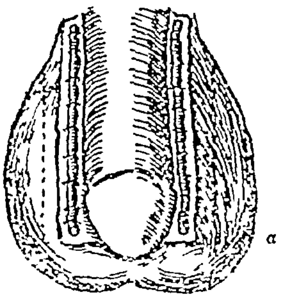
14. The medical referee shall, on receipt of an orde of reference duly signed by the registrar of a count court, together with copies of the documents require to be sent therein, fix a time and a place fo a personal examination of the workman, and shall sen notice to the employer and the workman accordingly. I shall be the duty of the workman, and, if the employer i the applicant, of the employer, or a person duly authorise by him, to attend at the time and place fixed by the medica referee, and in the event of failure on the part of the workman or employer, or both, to appear as required by thi regulation, the medical referee shall decide on the matte referred to him forthwith upon such information as shal be available, and with or without a personal examination: provided that where the absence of the employe or his representative, or of the workman, is shown to th satisfaction of the medical referee to be unavoidable, o where the medical referee considers it necessary to apply for expert assistance as hereinafter provided, it shall be open to him to adjourn the inquiry on the reference and to resume it at such a time and place as he may fix, having given due notice to all persons concerned.

15. Except as otherwise provided by Regulation 14, the medical referee shall, before deciding on the matter referred to him, make a personal examination of the workman, and shall consider any statements made or submitted by either party.

In addition to these regulations the notice required to be given by a medical referee to a workman as to the holding of an inquiry contains the passage: "Any statement made or submitted by you shall be considered," which is also found in the notice to be given to an employer, together with the following, to be used when the employer is the appellant: "You, or some person duly authorised by you, are hereby required to attend at the above time and place."

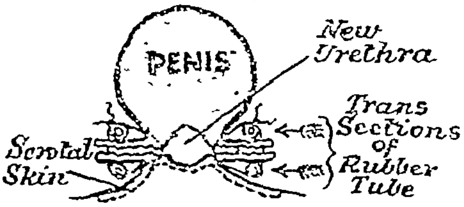
Referring first to the last-quoted sentence, and to the passage in the regulations bearing upon it, there seems little doubt that under it an employer might choose to be represented by a medical man, but it is unlikely that he would be allowed to gain any advantage thereby not within the reach of the workman. Turning to the other passages quoted it would appear that their meaning is that written statements of the conditions found to exist in the workman made either by his or by the employer's medical man can clearly be laid before the medical referee who thus will be aware of the questions at issue in the case before him. It is, however, no doubt intended that he should give a decision so far as possible his own after forming an independent opinion free from bias and from the influence of others. If it had been intended that a medical man should the tip of the penis fixes the catheter in place. The parts are dressed with lead lotion every four hours. On the fourth day the piece of catheter is removed and urine is allowed to pass down the new urethral tube. The sutures are all removed at the end of 14 days and the parts are ready for the second operation in from three to four weeks if the patient's condition is still favourable. Otherwise the second operation can be postponed indefinitely.

FIG. 5.



Shows penis fixed down on to scrotum and method of passing sutures through flaps over rubber tubes. The dotted line shows the outline of scrotal flap to cover in ventral surface of penis when dissected off the scrotum. *a*, Rubber tubes under sutures.

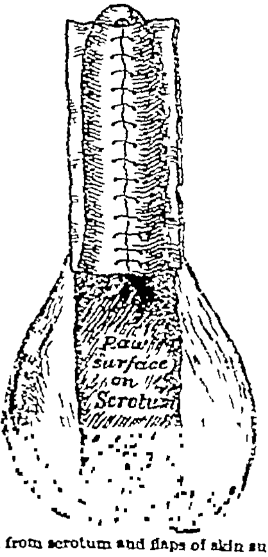
FIG. 6.



Scheme of suturing flaps round tubes to close urethra.

Operation, second stage.—The penis and new urethra are dissected up from the scrotum, lateral flaps derived from the scrotum being left attached on either side of the penis to close in the raw surface beneath it (Fig. 5, dotted line, and Fig. 7). Other flaps are formed on the scrotum; and by gliding them towards the middle line the raw surface on the front of the scrotum is easily closed (Figs. 7 and 8). If the lateral flanges used to unite the penis and scrotum in the first stage are seen to project too freely they can be trimmed off either now or later to improve the cosmetic result.

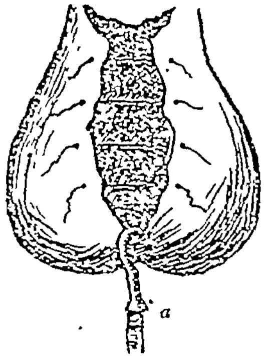
FIG. 7.



Penis raised from scrotum and flaps of skin sutured over.

I now propose to refer briefly to the cases in which I have performed this operation and afterwards to consider the advantages and disadvantages which the operation appears to possess.

FIG. 8.



Method of closing raw surface on scrotum after dissecting up penis and new urethra by dissecting up lateral flaps. *a*, Hook converting broad into narrow wound.

CASE 1.—The patient was a boy, aged four years. The misplaced urethral orifice was placed at the junction of the root of the penis and the scrotal raphé, the scrotum being uncleft. A well-marked median groove ran along the under surface of the penis, in the site where the urethra should have been. There was slight ventroflexion of the penis but no fibrous band tying it down. The false meatus was of good size

CASE 2.—The patient, a boy, aged two years, presented much the same deformity as did the patient in Case 1, but the scrotum was slightly cleft above and the meatus was so narrow that a preliminary plastic operation had to be performed to enlarge it so as to admit of the insertion of a catheter at the time of the real operation and to obviate the possibility of a stricture at this spot when the new urethra had been completed.

CASE 3.—The patient, a boy, aged three years, exhibited a very similar condition to that described in Case 1. His physical state was not good and consequently the first stage of the operation was done *à deux temps*, the half of the penis near the root being dealt with at one operation and that nearer the tip being sutured down to the scrotum at another, and the whole tube being subsequently dissected up in the usual way at a later operation.

The first two cases were treated five years ago and the third two years ago. The first two were followed for three years and remained as satisfactory in every way as could be desired. All the cases healed without delay and there was never any leakage or tendency to stricture.

The advantages which may be claimed for this method of operating are as follows: 1. That it is performed in two stages, each of which can be rapidly accomplished. This lessens shock and enables the operation being done at an early age, the ultimate plastic result being all the better in consequence. 2. That the skin utilised to form the roof and floor of the new urethra is not dissected up or even touched, consequently it retains its vitality and does not tend to slough as when flaps are used for this purpose. 3. That no sutures project into the lumen of the new urethra. 4. That the skin of the roof and floor of the new urethra is respectively in continuity with the roof and floor of the previously existing one. There is in consequence no tendency to the formation of a fistula or subsequent stricture at the site of the false meatus as so frequently happens when other methods are employed 5. No buried sutures are necessary and the apposition of the broad raw surfaces afforded by the flaps on either side, supported by the rubber tubes, prevents any tendency to leakage.

The disadvantages to be considered are two in number: (1) that the operation is only applicable if the scrotum is uncleft; and (2) that hair may possibly grow later on in life from the skin of the scrotal raphé which is used to form the new urethral floor. The former disadvantage is minimised by the fact that by far the larger number of cases of hypospadias are of the penile variety, and that should the scrotum be cleft as well the greatest trouble is not so much due to the deformity as to incontinence of urine which is incurable.

With regard to the possible growth of hair in the urethra leading to trouble there are several points for consideration: 1. If the strip of skin on the ventral aspect of the penis is cut wide so as to form the roof and sides of the new urethra, while that on the scrotum is narrower, so as to include little more than the raphé, it is evident that if hairs do develop they will be few, as the raphé grows few or none legislation, together with a marked increase in the general standard of living throughout the community, there should still exist a class of workers ground down by abject poverty and the greed of middlemen, living on a pittance scarcely adequate to maintain life, and working to earn this miserable wage for 14 or 16 hours a day with hardly an interval even for meals. That white slavery of this kind does exist among us is known but too well to those who work among the poorest classes in the East-end of London and a little book recently written by Mrs. ARCHIBALD MACKIRDY[1] gives a simple and unadorned account of the actual sufferings of some among them. It is beyond our province to deal with the social conditions which render it possible for such sweating to flourish as is here revealed—waistcoats made at 7*s.* 6*d.* a dozen, artificial violets at 1½*d.* a gross, and other work at similar rates, allowing a skilful worker to earn by unending toil some 6*s.* or 7*s.* a week. Nor can we discuss the remedies proposed, of which the one most hopefully regarded by the author is the fixing of a minimum wage for every industry, a plan already adopted with some success in that continent of social experiments, Australia. It is with problems of health that we have to deal and the sweating evil leads beyond question to serious violations of sanitary law.

The two main problems which strike the reader of Mrs. MACKIRDY'S book are the injury to the health of children by continuous work in the intervals between their school attendances and the dangers of spreading infectious diseases owing to the insanitary conditions under which much homework is carried out. How can we wonder at the miserable physique of many of our town dwellers when we find that children directly they come home from school are set down to some drudgery in the fœtid atmosphere of a crowded room, making paper boxes for sweets or crowns of flowers for candidates for confirmation, in order to help their mothers to earn the starvation wages by which they are barely kept alive? Often, indeed, they return home to find not only no rest but no food—to beg in vain for a crust of bread and then to go back again to school to have their starved brain-cells worried with more attempts at learning without the needed pabulum to maintain their activities. Nor is it only homework of this nature that is the lot of too many of the children in our elementary schools. Many act as errand boys and girls in their spare hours and are worn out with tramping the streets, often with heavy parcels to carry, during the time when they should be recruiting their energies by rest or play. To get up before daylight and to scrub an indefinite number of doorsteps before going to school is not a process conducive to health, and when we learn that this fate may befall a child of seven or eight years and realise the actual physical labour involved in carrying round the necessary implements and lifting buckets of water in the course of the operations we find it difficult to exult very loudly over the civilisation of the present age.

But there is another danger, that of the transmission of infectious disease by means of the articles manufactured by the sweated worker, which needs to be brought home to the other classes of society. In the crowded dens in which the workers live infectious diseases when they once break out must find a fertile soil. The overworked victims can offer little resistance to any morbid influence. Without food, without rest, without ventilation, they afford every essential condition for easy infection. And the materials on which they work are often well suited to convey contagion. The makers of cheap clothes habitually use the material which they make up for their own bedding. In one case quoted in the book before us a child with measles was lying covered with the stuff brought from the factory ready to be made into garments for others. In another instance the mother was lying on the bed with a child aged eight years who had "open tubercular wounds discharging," while the stench in the room was such that the visitor could scarcely endure to enter. All the other children were also suffering from tuberculosis. It is impossible to tell in what infection may lurk, for the proceeds of sweated labour are not sold only to the poor; they find their way into the houses of the rich. The ready-made garment, the neat card of hooks and eyes, the dainty paper box, the delicate artificial flowers, all alike are liable to bear the taint of their origin and to scatter seeds of disease. Truly—

> . . . . . "medio de fonte leporum
> Surgit amari aliquid quod in ipsis floribus angat."

Is there actually no remedy for this state of things or is it merely that our politicians are busy with more showy legislation and our social reformers are engaged in the pursuit of visionary Utopias? One fact at least is clear, and that is that the aliens who flock to our hospitable shores are the worst offenders in the conduct of sweated industries. The alien who starts as a sweated slave contrives in time to save a few shillings and starts himself to sweat others whom he finds ready to his hand. Parasites upon our community, these alien sweaters displace our own workers and drive ever downwards the price paid for home work. Yet little is done to protect our people against the invasion that is constantly in progress, and what little is done in a lucid moment by one Government is undone in a fit of sentimentalism by the next. The evil has been pointed out over and over again, yet it is still rampant in all our large towns and the misery which it causes is apparently increasing. If modern society—not only the society of the rich who too often care little for those beneath them, but also the trade union society which thinks only of its own members and the shop-keeping society a section of which grows rich on the proceeds of sweated labour—is too selfish to alter this system of slavery from moral motives, yet when the danger which it runs from the disease bred in the sweater's dens is made clear perhaps we may hope that self-interest may be sufficiently enlightened to insist on the removal of such plague spots from our midst.

OPENING OF AN ISOLATION HOSPITAL.—On Sept. 18th Colonel H. Lewis, the chairman of the Glamorganshire sanitary committee, formally opened, in the presence of a large gathering, a new isolation hospital which has been erected at Blackmill for the districts of Ogmore, Garw, and and Gilfach. The building, which is situated about a mile from the village, has been built at a cost of £7211, exclusive of £600 which have been spent for furnishing. The institution will provide accommodation for 12 patients.

[1] Baby Toilers. By Olive Christian Malvery (Mrs. Archibald Mackirdy), author of "The Soul Market." London: Hutchinson and Co. 1907. Price 2*s.* 6*d.*

œsophagus, the mediastina, the diaphragm, the liver, and the right kidney. The heart was shifted so as to lie wholly to the left of the mesial plane; in fact, the right edge of the right auricle formed a vertical line from the third to the sixth *left* costal cartilages about *one centimetre to the left of* the sternum (Fig. 3) instead of being on the right side of the right border of that bone. The apex of the heart was shifted downward to the extent of one intercostal space and outward to about the same amount. The transverse diameter of the organ was considerably reduced, chiefly by lateral compression of the right auricle (Fig. 2). The opening of the inferior vena cava in the diaphragm had moved across the mesial plane to the left side (Fig. 4). The vessel which it transmitted opened into the right auricle opposite the tenth dorsal vertebra. The aortic arch was rotated to such an extent that the three large arterial trunks springing from it came to be placed at their origin in the same sagittal plane, which was more than five centimetres from the mesial plane (Fig. 1). To reach its destination the innominate artery crossed obliquely behind the whole extent of the manubrium sterni (Fig. 3). The dragging of the large muscular portion of the crura of the diaphragm towards the left (Fig. 4) had compressed the aorta (A O R) to a flattened tube. This must have offered a considerable resistance to the flow of blood. The vena azygos major (to the right of the thoracic duct, T, in Fig. 2) was reduced to a very small size in the lower part of the *thorax; and in the aortic opening of the diaphragm and in* the neighbourhood of the superior vena cava no trace of this vessel could be found. In the whole of its course the thoracic duct was placed well over on the left of the middle line (Figs. 1 and 2, T) and the descending thoracic aorta had undergone a corresponding displacement. The œsophagus was slightly shifted to the left, even at its entry into the thorax, and became more and more pushed aside (Figs. 1, 2, and 4) as it descended, until in the lower part of the thorax it was as much as five centimetres from the mesial plane. At the same time, it became dragged away from the vertebral column (Fig. 2) and lay close to the pericardium at the anterior end of the long, attenuated posterior mediastinum. Although the right side of the œsophagus was everywhere flatter than the rest and had obviously been submitted to great pressure there was nothing to lead one to suppose that the permeability of the tube had been in any way affected.

FIG. 3.

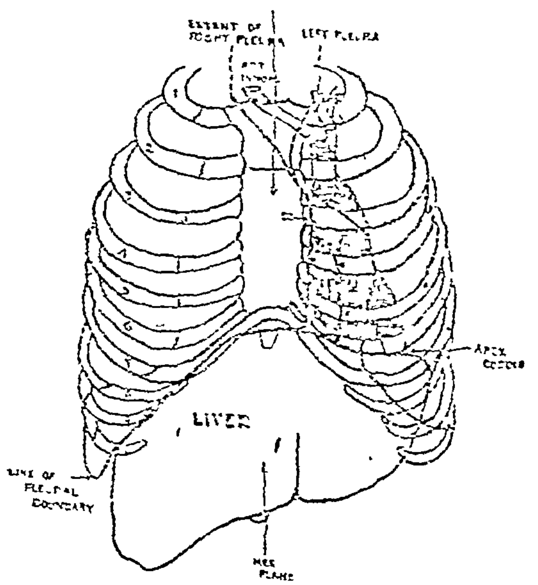

Diagram to show the lines of pleural reflection and the positions of the heart and liver. *x* * * * shows the left limit of the post-cardiac recess of the right pleural sac.

FIG. 4.

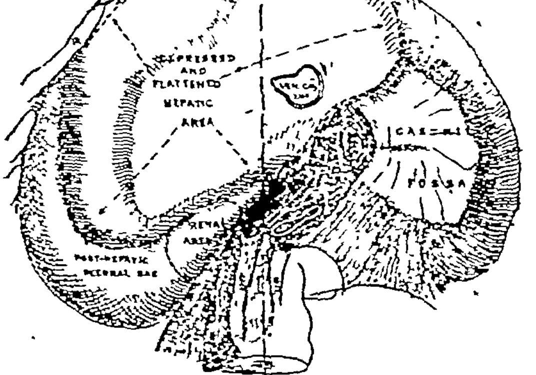

Diagram representing the under surface of the diaphragm in the same case. A O R, aorta. T, thoracic duct. C D, the crura of the diaphragm.

The trachea was not only pushed well over to the left but was also distorted (Fig. 1) The mediastinal spaces were all markedly compressed *from side to side* and were pushed bodily to the left with all their contents (Figs 1 and 2). The pushing forward of the heart resulted in a great antero posterior elongation of the posterior mediastinum, which became in section (Fig. 2) a narrow band of areolar tissue passing obliquely from the vertebral column to the pericardium. The liver was pushed completely out of the right side of the thoracic cage, and its supero-antero border, which was also the uppermost crest of the organ, exactly coincided with the right costal margin (Fig 3). The upper surface of the organ was flattened and formed a plane passing obliquely back from the costal margin toward the twelfth rib. The under surface of the corresponding area of the diaphragm is shown in Fig. 4. The liver was shifted downward and to the left; it passed *further under the left wall of the* chest than is normally the case (Fig. 3), but by far the greater part of its anterior surface was in direct contact with the anterior abdominal wall in the epigastric, hypogastric, umbilical, and right lumbar regions. The organ was pushed so far to the left that the gall-bladder was brought into the middle line. It was also displaced and slightly rotated forward by the extension downward of the pleural sac behind it (Fig. 4). One result of this was an undue prominence of the Spigelian lobe which formed a very large forwardly projecting boss on which the pyloric canal of the stomach was supported when the body was in the recumbent position. The left lobe of the liver came in contact with the spleen so that only a very small part of the stomach was actually in contact with the "gastric area" of the diaphragm (Fig. 4). The post-hepatic pleural sac pressing on the right kidney had pushed it downward and inward and had distorted its form. As the pleural cavity began to expand it left the posterior surface of the kidney and pushed its way down *in front of* the organ. At the same time the upper end of the kidney became truncated and moulded to the form of the angle between the right crus of the diaphragm (Fig. 4, C, D) and the pleural bag (Fig. 4, *renal ar a*). The right suprarenal capsule became wedged into the deep recess of the same angle and had become greatly compressed. The great splanchnic nerve (see Fig. 4, between the right crus (C, D) and the renal area on the pleural sac) was considerably larger than usual, as though it had become swollen by inflammatory infiltration. From the combined effects of stretching and the consequent disuse of the right half of the diaphragm *the muscular* tissue had undergone degenerative changes. Infiltration with inflammatory products might have had some share in causing this, for the hepatic and post-hepatic areas of the lower surface of the diaphragm were covered with a thick layer of lymph. The pericardium also contained more than the normal quantity of lymph, which is not surprising when we recall what a large area is exposed to the inflamed pleura (*Fig.* 2). In Fig 3 the lines of pleural reflection have been shown and in addition a line (* * *) has been drawn from the point *x* on the third costal cartilage outward and downward across the mid-points of the left fourth, fifth, and sixth costal cartilages to indicate (in relation to the anterior thoracic wall) the extent of the retrocardiac diverticulum of the right pleura. If a chart were drawn to show the relation to the back of this left extension of the right pleural sac it would be found to different countries, exact plans of so-called cancer "nests" and genealogical trees of families in which cancer has existed for several generations; (6) plans of cancer institutions and hospitals; and (7) proposals as to the means by which a knowledge of the importance of the early diagnosis of cancer may be brought home to the public. Exhibits should be forwarded between August 20th and 31st, 1908, to the general secretary of the International Surgical Society, Professor Dr. Depage, 75, avenue Louise, Brussels, who will take charge of the exhibits, will arrange for their exhibition, and at the close of the congress will return them to their owners. The programme of the congress will be so arranged that exhibitors can demonstrate their specimens to the members during its progress.

INSANITY AND MODERN WAR.

A RECENT issue of the *Allgemeine Zeitschrift für Psychiatrie* (Band LXIV., Heft 2) contains an extremely interesting article on the cases of insanity which occurred amongst the troops of Russia during the recent war between that country and Japan. The author, Dr. Awtokratow, was intrusted with the difficult task of organising the system for segregating and treating these cases and subsequently had charge of the Central Asylum for Insane Soldiers established at Kharbin, so that he was exceptionally well placed for obtaining authoritative information on the subject. In view of the terribly severe strain on the nervous system of the combatants which is involved in warfare under modern conditions it might reasonably have been anticipated that in an army so large as that engaged in the Manchurian campaign a considerable number of cases of mental disease would be likely to occur. At the outset, however, this very obvious probability was not apparently perceived by the Russian military authorities, and no special provision was made for the treatment of the insane who were accordingly detained in the ordinary field hospitals to their own detriment and that of the other patients. When the futility of this method had been sufficiently demonstrated in practice a more rational system was devised, and all cases of mental disease, after a preliminary period of observation in a sort of psychiatric ambulance, were sent to the central asylum at Kharbin. From Dec. 15th, 1904, when this asylum was opened, to March 18th, 1906, when it was closed the total number of patients received was 1349, of whom 275 were officers and 1072 belonged to the rank and file. As regards the relative frequency of the several forms of mental disease the two classes showed some curious differences. Amongst the officers chronic alcoholism was the commonest variety of insanity, occurring in 34·58 per cent. of the total number of cases, the other groups of numerical importance being neurasthenic insanity (11·2 per cent.) and general paralysis (10 4 per cent.). In time of peace, it may be remarked, general paralysis is the most frequent form of disease amongst officers, alcoholism being second on the list. Amongst the rank and file treated at Kharbin these two clinical varieties were comparatively much less common, chronic alcoholism amounting only to 10·86, and general paralysis to 4·3 per cent. of the total. Presumably the heavier responsibilities incumbent on the officers are in some measure accountable for this difference, the greater demand on intellectual activity contributing both to the development and to the detection of such disorders. The predominant form of disease amongst the soldiers was epileptic insanity, no less than 27·9 per cent. of the cases being classed under this head. Alcoholism and confusional insanity (*Verwirrtheit*) came next in importance. As to the cause of this remarkable frequency of the epileptic psychoses, which contrasts with their relative rarity in time of peace, Dr. Awtokratow considers that while it may be due in part to the less discriminating examination of recruits and the lower standard of fitness demanded in a time of emergency, it is also to be attributed in some measure o a direct influence of the stress of battle, for in several instances that came under his observation he ascertained that the patients, though of epileptic stock, had shown no symptoms of the neurosis until at the close of a severe engagement they were seized with convulsions followed by epileptic mania. Traumatic psychoses were relatively rare, amounting to 3·1 per cent. of the insanity of officers and to 3·6 per cent. of that amongst the rank and file. Of course, only those cases in which the mental diseases developed soon after the injury would have come under notice at the Kharbin Hospital. As might be anticipated, in the acute insanities, particularly in neurasthenic and confusional cases, the etiological influence of the war gave a characteristic colour to the mental symptoms, phases of panic terror, with hallucinations of bursting shells, pursuing enemies, putrefying corpses, and so forth, being especially frequent. In the cases of general paralysis described by the writer no such influence appears to have been perceptible in the delusions and hallucinations of the patients. The contrast thus shown between general paralysis and the acute psychoses in regard to the influence of the emotional shock causative of the disease on the affective tone and character of the delirium is in accord with what has been observed under like conditions elsewhere. In Paris, for instance, during the siege and the Commune, and in the disturbed districts of Russia within the last two years, the painful and terrifying experiences which gave a distinctive stamp to the thought and feeling in other forms of insanity did not appreciably modify the mental symptoms of general paralysis.

THE TREATMENT OF TETANUS BY INTRASPINAL INJECTIONS OF MAGNESIUM SULPHATE.

SODIUM and calcium salts have been shown to have stimulating effects on some of the bodily functions. It occurred to Meltzer that the salts of magnesium, another element found plentifully in the tissues, might have an inhibitory action on the same functions. In conjunction with Auer[1] he made a series of experiments on animals which confirmed this view. The subcutaneous injection of magnesium sulphate produced deep and prolonged anæsthesia, with muscular relaxation and abolition of reflexes. Intravenous injection affected the centres in the medulla, depressing the centres for respiration and deglutition, but not affecting the cardiac mechanism. Direct application of the salt to nerve trunks produced irritation but abolished conductivity which was restored on washing the salt away. Intraspinal injection produced surgical anæsthesia in monkeys, which led Meltzer to recommend its use in man. A few abdominal operations have been performed after the intraspinal injection of one cubic centimetre of a 25 per cent. solution of magnesium sulphate for every 20 pounds of body weight. This produced muscular relaxation, anæsthesia, loss of tendon reflexes, and slowing of respiration. In six out of 14 collected cases the patients lost consciousness. In only one case was the cardiac rhythm disturbed. Of untoward effects slowing of the respiration was the most serious and sometimes artificial respiration had to be performed. Washing out of the spinal canal with normal saline solution relieved this symptom. Meltzer suggested the intraspinal injection of magnesium sulphate in tetanus in order to relieve the spasms. A few cases have been reported in which this method was adopted with success. In the *Journal of the American Medical Association* of August 10th Dr. G. C. Robinson has recorded the following case. A boy, aged 11 years, weighing 70 pounds, than others. Dr. Halliday Douglas, long physician to the General Post Office at Edinburgh, saw many cases of nervous derangements and failures of health among the employees, especially those who did their work under high pressure. The female clerks often required leave of absence from illness. I have learned from several sources that monotonous work demanding severe and unremitting attention is most trying for the nerves and assists in causing mental derangement. Thus nervous diseases and insanity are especially common with telegraphists, letter sorters, and persons who have to check mechanical labour. The employments of the present day tend more and more to replacing work needing strength for the watching and direction of the play of machinery. The wear of the nervous system replaces the wear of the muscles.

---

[1] American Journal of Physiology, 1905 and 1906.

The increase of the grosser forms of nervous diseases in Great Britain.—In examining the statistics of the mortality from nervous diseases in the Register Office of Edinburgh, through the courtesy of the late Dr. Blair Cunynghame, and his successor, Dr J. C. Dunlop, one thing appeared to me at the outset—that those diseases of the nervous system which are assigned as causes of death are less frequent in Scotland than in England. To quote the Registrar's report: "While in Scotland in 1857 only 170 died of brain and nervous diseases in every 100,000, in England during the same year 273 deaths occurred in a like population from the same causes, and year after year the relative proportions remain somewhat the same in the two countries." The general death-rate for Scotland was in 1855 20·6 per 1000; in 1906 it was 15·993. In Scotland there died from brain and nervous diseases in 1855, 168 persons to every 100,000 of the population; in 1865, 179 persons; in 1875, 217 persons; in 1885, 231 persons; and in 1897, 221 persons, the increase from 1855 thus amounting to 53 persons, about one-third of the first number. The proportion of deaths in every 100,000 persons from diseases of the nervous system was: in 1855, 818; in 1875, 930; in 1885, 1210; and in 1897, 1109. In the report for 1897 we are told that from diseases of the brain and nervous system there were 9257 deaths, giving a mortality-rate for Scotland of 221 in every 100,000 and forming 11·79 per cent. of the total deaths. The rate for Scotland is exceeded by the principal and large town districts; the lowest fall in the insular and rural districts. One can only guess at the efficacy of the causes of nervous diseases in the gross. Drunkenness should be a potent factor, but there has been noted a decrease in the number of deaths from delirium tremens and chronic alcoholism in the last 30 years. And the excise returns of late years have shown a considerable diminution of the consumption of spirituous liquors. The number of deaths from diseases of the urinary organs has doubled from 1855 to 1897. Diseases of the circulation had also doubled during the same period. The mortality from pulmonary tuberculosis has during the last half century sunk by about one-half.

I did not make the same careful examination of the vital statistics of England, as this had been done in the book of Dr. A. Newsholme on that subject published in 1899. He showed that there is a great improvement in public health as indicated by a lower death-rate, commencing in 1872: it fell from 22·6 per 1000 down to 17·4 in 1897. Dr. Newsholme says that "it is doubtful if the increased strain of modern life exists in the community as a whole. Assuming, however, that over-pressure exists in certain stations of life—e.g., among city merchants, medical men, &c.—it cannot be said generally to exist among professional men; clergymen, lawyers, and civil servants are as classes long lived." But clergymen and civil servants generally lead easy lives and it is likely that anxiety and over-pressure may be felt less by the lawyers than by their clients. "Even assuming," goes on Dr. Newsholme, "that over-pressure exists throughout the whole of the professional classes, these do not form the mass of the community. The majority of the population of England and Wales belong to the wage-earning classes and the condition of these classes will therefore necessarily have the greatest influence on the total result." It is easy to prove that the working classes are now in a more prosperous condition than they were half a century ago. Dr. Newsholme, however, showed that there is a high death-rate from diseases of the nervous system amongst barristers and solicitors, railway stokers, and medical practitioners. Diabetes, a disease connected with disorders of the nervous system, has steadily increased, as also have renal diseases, which are high amongst medical men, lawyers, and innkeepers. Diseases of the nervous system show a death-rate per 1,000,000 of 1546 in 1861–65, and of 1600 in 1891–95. Dr. S. A. K. Strahan, in his book upon Suicide and Insanity (published in 1893) called attention to the fact that while the general death-rate for England and Wales has fallen 16 4 per cent. during the past quarter of a century, a rise, in some cases amounting to over 100 per cent., has taken place in the death-rates from hereditary and degenerate diseases. From a table compiled by Dr. Strahan it appeared that the death-rate in England and Wales in the 25 years between 1866 and 1890 had increased for nervous diseases by 10·2 per cent.; from diabetes, 103; from kidney disease, 63·4; and from heart disease, 65 9.

From these statistics it seems to me that it is not going in advance of the evidence to pronounce that the graver forms of diseases of the nervous system have increased in Great Britain, as they are said to have done in France and Germany, during the last 50 years. In Scotland there seems to have been some stoppage in the increase from 1885 to 1905, which, I hope, indicates that the rise of the death-rate from these maladies is not fatally progressive.

Increase of suicide.—Since the publication of Morselli's classical work "Il Sucidio" the attention of sociologists has been directed to the portentous increase of suicides in Europe and North America. This is most marked in large cities and seems to be progressing in every country in Europe save Norway. In the German empire the number of cases of self-destruction has risen from 10,510 in 1895 to 12,730 in 1905. According to statistics recently published by the Swiss Government there have been during the last 35 years 16,640 suicides in Switzerland, 323,600 suicides in Germany, and 274,000 suicides in France. It has been calculated that the yearly number in the whole of Europe amounts to 70,000. In Massachusetts it has increased in 30 years from 69·9 to 90·9 to the million living, and in Connecticut from 60·6 to 103·3 per 1,000,000. Dr. Charles Pilgrim,[2] the President of the New York Commission in Lunacy, tells us that Mr. Hoffman, statistician to one of the greatest insurance companies, made a compilation of the statistics of suicide relating to 50 American cities. From year to year the same sad story is told of an increasing propensity to self-destruction. In 1890 the ratio was 12, in 1900 it was 16, while in 1904 it had risen to nearly 20 per 100,000 of the population. In the British Islands the suicides have increased by 200 per cent. in 50 years and by 150 per cent. in 25 years. The following figures indicate the increase in England and Wales during the decade 1885–1904, inclusive:—

	In 1885	1904
Men	1529	2523
Women	478	822
	2007	3345

While some suicides are returned as having been drowned or killed by accident, few accidental deaths are registered as suicides. Altogether the stray errors and omissions in the registers are not sufficient to vitiate the general results. As the causes which tend to induce suicide are the same as those which go to produce insanity, greater sensibility and irritability and a lessened power of reaction, it is not surprising that those who have committed themselves by denying that insanity is increasing should be ready to question any rise in the number of suicides. Their position is incongruous, for as they advance that the increase in the number of registered lunatics is partly owing to the increased number of admissions of the early and milder cases of mental derangement they have to escape the awkward question, Why since many of these cases are of a pronounced suicidal character is there not a decrease instead of an increase in the gross number of suicides? The number of suicides committed under insanity have been variously estimated as between 20 and 30 per cent.; by others much lower. The number of attempts at self-destruction in an asylum is very large.

In Scotland the rise from 1865 to the quinquennial period of 1890–94 has been stated to be from a rate of 40 to a rate of 54, an increase of 35 per cent From my own inquiries I have found that in 1881 there were 182 suicides in Scotland—131 males and 51 females—out of a population of 3,735,573, giving a proportion of 48·7 to the million. During the quinquennial period within the years 1881–85 the mean annual number of suicides was 202, equal to 52·05 to clean them and to renew the vacuum but the bandage was not removed during the hour. Some cases did well from the beginning. In others the sinuses closed only to reopen. In two cases the method had to be abandoned on account of the occurrence of considerable hæmorrhage. Histologically there were observed dilatation of the capillaries and lymphatics and increased migration of leucocytes. At first the amount of discharge considerably increased but later it diminished. In some cases, however, the increase persisted and this seemed to impair the patient's general condition so much that the method had to be abandoned. The following are some examples. A boy, aged eight years, had had tuberculosis of the hip and a sinus for five years. After a month's treatment the discharge diminished steadily and the child gained 11 pounds in weight. A boy, aged three years, had tuberculosis of the knee. A plaster apparatus was applied and a compression bandage was used daily for six months. During this time the child walked about as before the onset of the disease. Marked decrease in pain and increase in movement of the joint occurred although in the upper part of the joint an abscess developed which opened spontaneously three months after the onset of the disease. The treatment was continued and a sterile dressing was applied. Then the suction treatment was begun and the sinus closed 16 weeks later. The patient had about 15° of motion in the joint and continued to wear a knee-splint for protection. A boy, aged nine years, had for four years tuberculosis of the spine and for nine months a sinus which followed incision and drainage of a psoas abscess. The discharge was profuse. Suction treatment was begun. In about five weeks the discharge greatly diminished and the general condition much improved. Of 16 cases treated, marked improvement or healing took place in eight. In five there was no local improvement but weight was gained and the colour index of the blood rose.

HUMAN TERATOLOGY.

To Geoffroy Saint-Hilaire science owes the first really systematic study of monstrosities and anatomical malformations and his "Philosophie Anatomique" needs little more than supplementing to maintain the authority which it has hardly lost since its publication in *1818–20*. No nationality is exempt from what the older investigators called "Lusus Naturae," the British Isles being not the least prolific in these phenomena. Scotland in the first decade of the sixteenth century anticipated China in the second decade of the nineteenth in producing "twins" like those called from their birthplace "Siamese." Buchanan in the thirteenth book of his "History of Scotland" describes this "monstrum novi generis in Scotia natum" as in the lower part of its body resembling a male child in no wise differing from the normal; but above the umbilicus the trunk and all the members were double, representing both sexes. "Id Rex," he tells us, "diligenter et educandum et erudiendum curavit; ac maxime in musicis, qua in re mirabiliter profecit." Nay (he proceeds), it mastered various languages, while the two bodies betrayed diverse wills and would sometimes fall out with each other. When they agreed they would hold a consultation in the interests of both. This, too, was remarkable, that any hurt to the legs or loins below was felt by both bodies, but when the hurt was inflicted above the pain evoked response in one body only. One of the bodies, he adds, died several days before the other, but the survivor gradually pined away. "Vixit id monstrum," he concludes, "annos XXVIII. *Hac de re scribimus eo confidentius quod* adhuc supersunt homines honesti complures qui haec viderint." In all this we seem to be reading an account of the "Siamese twins" who died in 1874, aged 63 years. Among contemporary nationalities Italy (as THE LANCET, in its Italian correspondence, has from time to time put in evidence) contributes the most numerous, as well as the most bizarre, specimens to the repertory of teratology. In the day now passing her professional journals record the following: In the Island of Sardinia a peasant woman, after prolonged labour lasting three days, was delivered of a gruesome monstrosity. The head of the child (male), normal in size and oval in contour, is without hair; the face is "framed," so to speak, with long hair; the eyes are in the middle of the forehead; the ears are absolutely wanting. In the middle of the thorax there is a "*croce*" (cross) formed of hair which covers the backbone, the legs, and the arms, and is at once very long and fine. The hands are wanting. This monstrosity is still alive and the mother, who, it appears, has not yet been allowed to see it, is doing well. From the physical to the moral and intellectual monstrosity, says one of the commentators on the above, there is but a step—how short and how frequently taken let the criminal-lunatic asylums of Italy bear witness.

COÖPERATION FOR ASYLUM NURSES.

DURING the past two months there have been several notes in the *Nursing Times* on the subject of asylum nurses. Attention has been drawn to the fact that there is no coöperative nursing home for these nurses similar to those staffed by nurses who have been trained in general hospitals. We are aware that at least one nursing coöperation has asylum-trained nurses on its staff, but it would appear both in the interests of the public and for the better recognition of fully-qualified asylum nurses that a home should be started which shall only supply properly trained nurses who in return shall have the advantages of working under a coöperative system in the matter of their remuneration. We presume, as a guarantee that the nurses so supplied have attained a certain degree of efficiency, that they will be expected to hold some recognised certificate such as that granted by the Medico-Psychological Association of Great Britain and Ireland. We are informed that Miss *Jean Hastie* is starting early in October a "Mental Nurses' Coöperation" which, we understand, has the sympathy and support of several consulting physicians in psychological medicine, and if properly managed the scheme should prove a successful one.

DIPHTHERITIC ENDOCARDITIS.

IN THE LANCET of Sept. 21st, p. 826, we published an unusually interesting case of malignant endocarditis of diphtheritic origin recorded by Dr. J. T. C. Nash. The patient was a child between three and four years of age. The clinical history of the case is worthy of notice. The primary disease (diphtheria) was of so slight a nature that it had passed practically unnoticed. It was only on cross-examination of the parents of the child after a *post-mortem* examination had been made that it was ascertained that he had suffered from ear-ache and a discharge from the ear three weeks previously; sore throat, however, had never been complained of. Doubtless such slight cases, owing to non-recognition, may be the starting-points of severe epidemics. When brought under medical notice the boy had headache, loss of appetite, furred tongue, constipation, and a fugitive erythematous rash. The later symptoms of occasional delirium, restlessness, and tenderness along the back with a continuance of drowsiness, headache, and fever, had suggested the possibility of malignant endocarditis. 36 hours before death retraction of the head and strabismus, and later a petechial rash and slight opisthotonos, led to a suspicion of cerebro-spinal meningitis. At the necropsy on examination of the heart vegetations were found on the aortic and mitral valves. On bacteriological examination a population of patients in public asylums rose from 167 in 1850 to 410 in 1903. From 1884 to 1903 the average ratios of first admissions per 10,000 of population were for the four five-year periods 4·7, 5·3, 5·8, and 7·0 respectively, denoting an increase in the second quinquennium over that of the first of 12·7, in the third of 9·4, and in the last of 20·0. The death-rate in the Irish asylums is low.[6] Some of this increase is put down to the reduction of the population by emigration of the mentally fit, and partly to the return of emigrants suffering from mental breakdown; perhaps some of these have not been allowed to land in America. It is too easy an assumption to say that the emigrants all belong to the mentally fit, for it has been observed that the proportion of insane among the Irish admitted into the State asylums in America is more than double those of other nationalities. The Irish Lunacy Blue Books give a powerful support to the belief in the absolute increase in insanity.

[After giving figures to show the increase of insanity in France, the Netherlands, and the United States, Dr. Ireland came to the following general conclusions.—]

General conclusions.—It has been argued in various journals that the increase of insanity is only apparent. With insular narrowness the writers confine their attention to the British Isles. They assign the increase of certified insane persons to the accumulation of chronic cases, to a diminished death-rate, to the straitened circumstances of relatives, to the greater readiness to grant admission to all cases of mental failure, aided by the 4*s.* grant from the Exchequer allowed 30 years ago to ease the poor-rates. Then they try to throw suspicions upon the census returns. To most of their objections no determinate value is assigned. They are magnified by rhetoric, and all pointed one way to bring out a case of not proven. All that they know is nothing can be known

It has been advanced by those who combat the belief that there is a real increase of insanity in Scotland that there is little addition to the number of private patients, the rise being mainly in pauper lunatics, but when one looks at the naked facts he sees that it could scarcely be otherwise. During the last 45 years the smaller asylums which took in those who could pay moderate boards have been squeezed out of existence. The few private asylums remaining are obliged to charge much higher, and the general expenses for the upkeep of the insane have much risen. For many years back it has been the custom that those bearing the burden of a lunatic relation who are anxious to pay what they can go to the inspector of poor who transmits it to the treasurer of the asylum. Thus, a considerable number of persons who would formerly have been private patients are now officially returned as pauper lunatics, although they are not really so. This no doubt makes it easier for people to get rid of the burden of supporting a lunatic dependent than formerly. Much stress is laid upon the greater willingness of the friends of lunatics to send them into asylums owing to the increase of confidence and the skilful and humane way in which asylums are now managed. This, of course, is an argument most pleasing to the superintendents of these institutions. It is capable of indefinite extension. A sudden leap upwards in the admissions only means that the public confidence in asylum stock had risen. I am far from insinuating that this increased confidence or lessened distrust is not what it should be, but I am doubtful of its extent and intensity. It is but a few years ago since, owing to a popular outcry of suspicion, the superintendents in England were shackled with a new Lunacy Act, bristling with galling restrictions and insulting returns. Few people know anything about asylums till some of their relations go mad and then they get them out of the house simply because they have become intolerable in it. What keeps them back from doing so is mostly the expense, which is assuredly not diminishing, for patients whose friends can pay. Moreover, the belief in the hereditary transmission of insanity and idiocy, so often reiterated by the medical press, has now fairly reached the popular mind. Nowadays the stigma of insanity is attached to the whole family, whereas formerly it was but attached to the individual. It is felt like an incapacity and a hindrance to marriages. Hence there is an increased unwillingness to make an admission of an ancestral taint by such an overt act as sending a member of the family into a lunatic asylum, with all the formal scrutiny and certificates required by the laws. That this has a considerable effect in keeping down the admission among the wealthier class I have no doubt. While granting something to all these explanations so ingeniously pleaded, it is the outcome of my inquiries that they fail to account for the whole increase of insanity. I should say that we have to deal with an advance along the whole line, an increase in nervous diseases, in suicides, and in lunacy.

In the well-known work "Psychiatrie," by Dr. Emil Kraepelin, I find a complete agreement with my views. I translate one passage: "On the other hand, regular census with us indicates with certainty a rapid increase of the insane which far overtops the general increase of the population. No doubt this rise is partly accounted for by the greater ease of the numeration and the better knowledge of insanity. Nevertheless, I believe we cannot any longer doubt that we have *actually to reckon with* a very considerable increase in insanity. This is proved, not only by the alarming increase in the number of the insane, but also by the simultaneous rise in the frequency of suicides and the contrast presented by the town and rural populations."

The learned professor observes that we are living in a time of transition and he hopes that coming generations will be able to enter on the stress and struggle of life with fresh strength and better weapons. We need not believe that this increase of diseases of the nervous system is destined to fatal progression; it may stop or it may retrocede ere long. It would be rash to assume that we are acquainted with all the causes, and the means of prevention are not entirely beyond our control.

Musselburgh.

THE TREATMENT OF RHEUMATOID ARTHRITIS.

BY W. J. MIDELTON, M.R.C.S. ENG., L.R.C.P. LOND.

DURING the last six years, in treating rheumatoid arthritis, I have had recourse to counter-irritation of the spine by means of blisters applied in the neighbourhood of the cervical and lumbar enlargements and have found it a most useful therapeutic agent, perhaps *the* most useful, in dealing with this very intractable ailment. I have arrived at this conclusion, not only from the results which have been obtained in the treatment of some 20 patients of my own, but after personally examining a very large number of cases in London, Bath, Buxton, Matlock, and other places and comparing the results obtained there, following on the use of radiant heat, massage, diet, drugs, and mineral waters, &c., with my own.

This plan of treatment was recommended some years ago by Dr. P. W. Latham[1] of Cambridge, who bases his theory on the fact that "clinical experience has taught us that injuries to the spinal cord or even to the nerves of a limb will set up arthritic changes which cannot readily be distinguished from those seen in the earlier stages of rheumatoid arthritis." And secondly that "pathological facts appear to show that the trophic nerves of the bones and joints are found in the mixed nerve trunk, and that they issue along with the motor fibres from the anterior cornua of the spinal cord, where they are, like the muscular trophic fibres, connected with a group of large caudate cells," and that "it seems now generally admitted that both irritative and destroying lesions of the ganglion cells of the anterior horns of the spinal cord and their homologues in the medulla oblongata, pons, and crura, or of the efferent fibres which unite these cells with the periphery, may give rise to active atrophy of muscle."[2] From these pathological and clinical facts Dr. Latham infers that the changes in the joints and the muscular wasting which are characteristic of rheumatoid arthritis are due to irritative and destructive lesions located in the spinal cord and especially in the cervical and lumbar enlargements. With this theory as advanced by Dr. Latham I may not be altogether in accord, regarding the disease as I do as in some measure due to a cerebro spinal toxæmia. As to the beneficial effects, however, of this plan of treatment, when efficiently carried out, the notes of the following cases which have been under my care furnish ample and convincing evidence.

[2] Ross: Diseases of the Nervous System, second edition, vol. I., p. 241.

earlier period of the disease. Antitoxin has not the slightest effect on these cases. 6000 units were generally given.

CASE 1.—The patient was a boy, aged five years, who was admitted on May 28th, 1905, on the sixth day of illness. The characteristic symptoms developed on the 30th—i.e., on the eighth day of illness—and he died on the 31st. On admission he had the grey, anxious look of these malignant cases but the symptoms of vomiting and reduplicated heart sound did not show themselves until the day before he died. In him the apex beat was displaced downwards and outwards but this condition is not ordinarily present.

CASE 2.—The patient, a boy, nine years old, was admitted on August 4th, 1906, on the fourth day of illness. His mother looked after her children very well and so soon as symptoms of sore-throat developed she took him to her medical man who injected antitoxin and sent the boy into the hospital, where 8000 units of antitoxin were given on admission. At this time there was thick dark membrane, easily detachable and foul smelling, on both tonsils and uvula, and the cervical glands were much enlarged. On August 5th a large amount of albumin was present in the urine. On the 7th there was green vomiting, the pulse was slow and feeble, and the rhythm of the heart sounds was altered. The amount of urine passed was as follows: on the 6th, 20 ounces; on the 7th, 13 ounces; on the 8th, six ounces; on the 9th, four ounces; and on the 10th, two ounces. The patient died on the 10th. This case shows the uselessness of antitoxin even when injected early. In this patient the dangerous symptoms developed on the seventh day of illness.

CASE 3.—The patient, a boy, aged seven years, was admitted on the seventh day of illness with a nasal and pharyngeal diphtheria; the urine contained one-eighth of albumin. The dangerous symptoms developed on the fourteenth day of illness and he died on the seventeeth day. A well-marked symptom in this case was sighing, which was followed by a slight groan on expiration.

CASE 4.—The patient, who was six years of age, was admitted on the fourth day of illness and he died on the seventh day. The characteristic symptoms were present shortly after admission.

CASE 5.—The patient was aged six years and was admitted on the eighth day of illness. The characteristic symptoms appeared exceptionally late—namely, on the nineteenth day of illness. The patient died on the twentieth day.

CASE 6.—The patient was three years old and was admitted on the fourth day of illness with nasal and pharyngeal diphtheria. The dangerous symptoms developed on the seventh day of illness and death occurred on the thirteenth day.

CASE 7.—The patient was a girl, aged two years and five months. She was admitted on the fourth day of illness, when 8000 units of antitoxin were given. The dangerous symptoms developed on the eighth day of illness and she died on the tenth day.

CASE 8.—The patient was aged five years and was admitted on August 17th last, on the fourth day of illness. Vomiting commenced on August 20th (i.e., on the seventh day of illness) and on the 21st (i.e., on the eighth day of illness) the heart sounds were heard to be reduplicated and abdominal pain was complained of. The patient died on the 24th.

These grave symptoms can appear early in the disease. In one case they appeared on the fourth day of the disease.

Examination of the swabs from these throats shows large numbers of streptococci and staphylococci associated with the Klebs-Löffler bacilli, and some observers (Roux and Martin) have been led to regard such an association as unfavourable, and, in fact, the cause of the fatal termination. Against it is the circumstance that these symptoms never develop in other septic diseases, such as scarlet fever, for example. The striking feature is the uselessness of antitoxin in these cases. It is possible that there are several kinds of diphtheria bacilli which elaborate different toxins and such toxins will be only neutralised by special antitoxins. If such be the case it would be worth while to have antitoxins prepared from the bacilli derived from these cases and used for such cases. Streptococci which were at one time thought to be alike have now been found to represent a number of distinct organisms and the same may be found in the case of diphtheria bacilli.

I am indebted to Dr. Henry E. Armstrong, the medical superintendent of the hospital, for permission to report on these cases.

Newcastle-upon-Tyne.

HOSPITALS AND TAXATION.—Mr. P. J. Langdon, the secretary of the South Devon and East Cornwall Hospital, was summoned before the Mayor of Plymouth on Sept. 23rd for keeping a male servant without a license. The male servant was the hospital porter and the hospital committee accepted the responsibility of the case. After some discussion it was agreed that the duty should be paid, and the summons was dismissed. The supervisor of taxes applying for costs against the hospital, the mayor said that the bench regarded it as somewhat of a hardship that the hospital should be called upon to pay but at the same time he had no option and he would pay the costs himself; however, the supervisor of taxes remarked that he himself was in sympathy with the institution and agreed to the remission of the costs.

THE TREATMENT OF MAMMARY CARCINOMA BY THE LOCAL INJECTION OF PANCREATIC FERMENT.

By REGINALD MORTON, M.D. TOR., F.R.C.S. EDIN.,
MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT OF THE LONDON HOSPITAL;
AND
H. EMLYN JONES, M.R.C.S. ENG., L.R.C.P. LOND.,
CLINICAL ASSISTANT AT THE ELECTRICAL DEPARTMENT OF THE LONDON HOSPITAL.

DURING the last year or so much has been written and much more spoken concerning the use of trypsin in various forms for the treatment of malignant disease, some advocating its use and publishing results[1] which made it hopeful that at last we had an agent which, if unable to cure the disease, had at least a favourable influence on the course of it, relieving the pain to a great extent, preventing the progressive loss of weight, and in some instances actually modifying the morbid process itself. The results obtained at the Clinical Research Laboratories of the Middlesex Hospital[2] and the conclusions drawn therefrom (results and conclusions with which the following cases entirely agree) seem to make it doubtful whether any benefit whatever can result from such treatment.

The following cases are interesting in many ways, more particularly because it was decided to treat a certain number of typical cases of malignant disease of the breast in various stages by these methods, together with the application of x rays and comparing the results with those obtained by the use of x rays only. Four cases of carcinoma of the breast were chosen, three of which had been operated upon and one fungating atrophic scirrhus, considered to be quite inoperable. Of the three cases operated on there was slight local recurrence manifest in two, and in the other no recurrence except a small and very questionable lump in the axilla. The applications of x rays were given through tungstate two or three times a week at intervals of two or three days, according to whether any dermatitis was present or not. The duration on each occasion was 30 minutes. For the first few injections Allen and Hanbury's sterile trypsin was used, followed afterwards by the same firm's trypsin co. (trypsin and amylopsin). Doses of 15 minims were commenced with, gradually working up to 30 minims. Fresh bottles were used on each occasion and strict aseptic precautions were observed in each case. The prick of the needle was always dressed afterwards with cyanide gauze soaked in collodion. The injections were usually made into the skin and subcutaneous tissue near the site of the growth, but occasionally into the arm. Excepting for slight relief of pain for about a week in the atrophic case and some improvement in the general condition of Case 3, especially as regarded the appetite during the period of the first six injections, no good whatever resulted either as regarded the disease itself or the general condition of the patient. In Case 2 very rapid dissemination and cachexia have occurred and already within a few months of operative treatment the patient is continuously confined to her bed. Comparing this with exactly similar cases, in which x rays were used alone, we cannot help thinking that the injections were the cause of the rapid dissemination. After a few injections the pain was in every case increased, and afterwards, when larger injections were used, inflammation and occasionally suppuration occurred, exactly the results obtained at the Middlesex Hospital.

Dr. Benjamin Moore in 1905[3] pointed out, and it is now generally recognised, that there is a diminution of the gastric hydrochloric acid in almost all the cases of carcinoma not only of the stomach itself but of practically all other organs, and Dr. S. Monckton Copeman[4] suggests that the cachexia, loss of appetite, and general ill-health of patients suffering from the disease are consequent on the chyme which enters the duodenum from the stomach after a meal being insufficiently acid to stimulate an adequate amount of pancreatic secretion and put to bed, and the family physician was sent for. Before he arrived the paralysis had invaded both upper extremities. I saw her the same evening. She was conscious, suffering no pain, but had absolute paralysis of the four extremities. The reflexes were abolished and sensation was normal. The temperature was normal. There was no paralysis of the bowels or bladder. Faradic contractility was present. On the next day I saw the child again in the evening and noted that in addition to the paralysis of the four extremities there was a marked effort of the accessory muscles of respiration. In spite of any treatment the child died at midnight, 55 hours after the onset of the disease. No necropsy was allowed.

[4] Recent Research Work in Cancer, Practitioner, August, 1907.

CASE 3.—On Nov. 16th, 1905, I was called by the family physician to see a patient, 16 years old, who had been in her usual state of health until Nov. 15th. At that time, without pain, she lost all use of her lower extremities. The paralysis rapidly ascended the trunk and upper extremities until she was totally paralysed in 30 hours from the time of onset. I found her seated in a chair, the trunk bent well forward, and the head supported by a nurse. She was breathing rapidly, but said that she felt no discomfort. I tested her reflexes and found them absent, found sensation present, and found that there was no loss of control of the bladder or bowels. Faradic contractility was present. She was ordered fluid extract of ergot and Credé's ointment rubbed in freely along the spine. She gradually failed from the loss of power of the respiratory muscles, which was preceded by paralysis of the muscles of deglutition, and she died on the 20th, five days after the onset. No necropsy was allowed.

CASE 4.—On Nov. 30th I was called by the family physician to see a patient, a man aged 50 years, who was in bed with total paralysis of all four extremities. The previous history was that the man had been in his usual good health until Nov. 30th, when he felt a weakness in his legs and rather a sharp pain in the muscles of the right calf. He walked to a barber's shop with difficulty and sat in a chair to be shaved. When this operation was completed he tried to get up from the chair but found that he had lost all power in the muscles of the lower extremities. He was taken home and the family physician was sent for. Paralysis advanced rapidly from the muscles of the lower extremities to the muscles of the trunk and upper extremities, so that when I saw him, 48 hours after the onset, he was totally paralysed in all muscles below the neck. There were no loss of sensation and no loss of bladder or bowel control and the reflexes of the knees were absent. The reflexes in the plantar surface of the feet were present. The man had previously had a slight cold and as a result of the paralysis of the muscles of expiration he had not sufficient expiratory power to expel the mucus, and there was a loud rattle to be heard during respiration. I agreed with the family physician in the diagnosis of Landry's acute ascending paralysis, told him of my experience in the use of the Credé's ointment in one case, and suggested that we should use it freely. An ounce was rubbed in the back, thighs, and axilla in the following 24 hours. The first morning after my visit it was evident that the spread of the disease up the cord had been arrested. Respiration was quiet and the difficulty in swallowing, which was quite apparent the night before, no longer existed. The treatment of ergot and unguent Credé was continued. Six weeks from the onset there was some return of power in the muscles of the feet and hands. At no time was faradic contractility lost. In three months he had good use of the arms and legs.

CASE 5.—In December, 1906, I was called by the family physician to see a patient with the following history. He was a young man, aged 22 years, in previous good health, whose occupation was office work. He had started three days before I was called to go downstairs and walk to his work and complained that his legs felt heavy and that locomotion was difficult. He returned to his home and sent for the family physician, who at that time examined him and found that there was no paralysis, that the reflexes were normal and sensation was normal, and he advised him that the trouble was transitory and would probably pass away in a day or two. On the next day the legs were still more affected. The man became frightened and hysterical. On the third day the arms became involved and breathing was difficult. At that time I was called to see him. When I examined him I found the man sitting up in a chair with his body bent forward and breathing with great difficulty. There was an anxious expression. His hands and legs were absolutely without movement; sensation was normal. Electrical examination showed faradic contractility in all the muscles of the four extremities. The reflexes were normal. There was control of the bowels and bladder. I attempted to give him water but the difficulty of swallowing was so great that alarming choking occurred. A diagnosis of Landry's paralysis was made, the symptoms of the disease being all present as high as the respiratory centre. On the evening of the fourth day the man died. No necropsy was allowed.

CASE 6.—In the fall of 1904 I was summoned to see a patient by the family physician. I found a stalwart young man, aged 30 years, single, with a previous history of urethritis for the past six weeks. There was nothing unusual about this urethritis. The history given by the patient was that 48 hours before I saw him he was starting to dress and found difficulty in standing on his right foot, but he managed to dress and walked downstairs and kept about during the morning. As he felt himself getting weaker he returned to his room but found himself unable to walk upstairs: he, however, managed to get up on his hands and knees and went to bed. On examination I found paralysis almost complete of the two lower extremities and great weakening of the muscles of the arms. In this case I found tenderness along the sciatic nerve trunks and along the crural nerves. There was also tenderness along the nerves of the brachial plexus. There was diminished sensation in the skin of the four extremities. A diagnosis of acute infectious multiple neuritis was made and a favourable prognosis was given. He was under treatment for a period of three months. During this time the reflexes were lost, sensation became more and more blunted, and the faradic contractility was greatly impaired. He was treated on the theory of some toxic principle having caused the widespread inflammation of the nerve trunks. I used inunctions of unguent Credé freely and subcutaneous injections of the normal salt solution every eight hours for a period of two or three weeks. At each injection I used from eight to 12 ounces. Sensation was normal and the reflexes all returned and he was entirely recovered at the end of six months.

CASE 7.—In December, 1904, there came to me a man with a history of a purulent venereal sore about six weeks before the onset of a paralysis which affected the muscles of deglutition. Before the onset of the paralysis he worked for an estimated period of 45 days in five weeks. At the end of this time the first evidence of paralysis was noticed in a change of the quality of his voice. This was followed by difficulty in swallowing. This paralysis rapidly increased until the swallowing became fraught with danger and there was no sound from the glottis. Respiration was difficult and was carried on almost entirely by the aid of the accessory muscles of respiration. There was marked weakness of the muscles of both arms and legs but there was no paralysis of any muscle or group of muscles in the extremities. The patellar reflexes were much diminished; the Babinski sign was absent. There was no anæsthesia but he complained of paræsthesia in the arms and legs. Disturbances of sensation were described by him as a feeling of numbness such as is observed when the feet and hands are cold. Examination of the muscles of the extremities by the faradic current showed that the faradic contractility was not lost. The onset of this case, following as it did purulent discharge, and also following severe physical labour with excessive number of hours and deficient sleep, causes me to hesitate between the diagnosis of myasthenia gravis and acute bulbar paralysis. I called two laryngologists in consultation and they reported to me that the glottis was in a cadaveric position and that the aphonia was due to organic disease and not to hysteria. Dr. William C. Krauss was notified to attend the case in consultation with me. He was of the opinion that we had to deal with acute bulbar paralysis, but after a period of three months the paralysis had gradually disappeared. The muscles that were first affected recovered first. At the end of six months the patient had recovered sufficiently to be allowed to go home. A year later he was a robust, vigorous man entirely recovered and able to perform his duties as before.

The diagnosis in this case, considering the severe and complete exhaustion after his heavy work, and the respective facts that there was no actual paralysis of the muscles of the arms and legs and that there never was any tenderness along the nerve trunks, made it probable that we did not have a case of either Landry's paralysis or of infectious multiple neuritis. The physicians who saw him could never the germs. In other words, it impairs or destroys the protective power of the bronchial or pulmonary epithelium by occasioning some chemical or biological change in the cells by virtue of which the pneumococcus is enabled to find suitable soil for its growth. This view is now held by many authorities to be the correct one. The symptoms and physical signs of the disease are well described and some suggestive remarks are made as to its duration. It is generally known that the course of the malady may be protracted by complications or by delayed resolution. The last-mentioned possibility, however, furnishes a fruitful theme for discussion. It was formerly taught that instead of resolution taking place within a few days or a week, as is usual, it might be retarded by factors which were not altogether understood. Dr. Babcock points out that the opinion now seems to be gaining ground that the persistence of dulness, bronchial breathing, and even of crepitant râles is to be attributed not to slow absorption of the exudate but to its conversion into fibrous tissue—that is to say, the exudate undergoes organisation and that portion of the lung becomes permanently indurated. There is pathological evidence in support of this assertion. It must also be borne in mind that some cases diagnosed as "unresolved pneumonia" eventually prove to be instances of empyema. The treatment of acute fibrinous pneumonia is most ably and fully described. After some preliminary remarks on "various proposed modes of therapy," the author arrives at the conclusion that "woefully inadequate as are our weapons against this terrible foe to mankind, we possess no better mode of therapy than what is known as the expectant or symptomatic plan of management."

We can recommend to our readers a perusal of Dr. Babcock's remarks on the "general management" of a case of pneumonia; much useful information will be gained thereby. He is eloquent on the importance of a full supply of fresh air. He says: "We have all seen pneumonia sufferers in rooms and wards so close and hot as to cause a person entering from the fresh air of the outer world to feel faint and half sick. ...... Can anything be more absurd than to see an oxygen apparatus in a room the windows and doors of which are closed and the atmosphere stifling from heat and foul emanations from patient and attendants? The notion that a pneumonia patient must be protected from cold air and draughts originated at the time when this affection was considered an inflammation of the lungs resulting from exposure. The modern view of its pathology renders ridiculous the fear that fresh, cold air is harmful. In my opinion, even a draught is less dangerous than is the lack of proper ventilation." These words show that Dr. Babcock has the courage of his convictions, and in insisting on light coverings for the patients and the absence of the "cotton jacket" and heavy poultices he is carrying out a form of treatment which is being more and more adopted. He naturally has a high opinion of the advantages of cold as an antipyretic and gives minute directions as to the manner in which it should be employed. We have not space to dwell further on this subject but we consider that Dr. Babcock's views are founded not only on a large experience but also on sound scientific principles.

The subject of pulmonary tuberculosis justly demands the most full consideration and eight chapters were found necessary in order to accomplish this. Although heredity in connexion with this disease does not occupy the prominent position in regard to etiology that it once did, yet we consider that Dr. Babcock's contentions go too far in the opposite direction. We find a little difficulty, also, in ascertaining his exact meaning. In discussing the "natural lack of tissue resistance," he says: "Whereas I do not any longer believe in congenital predisposition (i.e., tuberculous diathesis) as the main or even an important etiological factor, I do yet believe that not all individuals are equally prone to pulmonary tuberculosis." Then, further on, he remarks:—"I still cling to the view that by reason of an inherited or congenital weakness of constitution the descendants of tuberculous forebears are more liable to develop pulmonary phthisis than are children of a more rugged stock." Again, when giving a summary of his views, he says:—"Finally, the so-called tuberculous diathesis or inherited predisposition to consumption is a belief based on wrong hypotheses. The whole subject must be looked at from the viewpoint of infection and not hereditary tendency." The above statements are rather difficult to reconcile, for the difference between "tuberculous diathesis," "inherited predisposition," and "an inherited or congenital weakness of constitution" is so slight as to resolve itself into one of terminology only. The elaborate statistics evolved from the various life assurance societies bring out one cardinal fact, that is, that applicants who have lost near relatives from tuberculosis show an excessive mortality from this cause. There is certainly a tendency at the present day to decry the influence of heredity in connexion with tuberculosis but care must be taken that extreme views do not prevail.

With regard to another debateable point also Dr. Babcock asserts his strong belief in infection as being the main element in the spread of the disease, and that is in reference to "compulsory registration." He says: "The fact is that this measure is so fundamental that unless it be carried out no adequate prevention of this disease can ever be attained." This may eventually prove to be correct but there are serious objections to the enforcement of compulsory notification. There are many authorities who doubt its efficacy and who believe that as much can be done by a continuance of those measures which have already so materially lessened the mortality of the disease. The improvement of the dwellings of the working classes and the instruction given to patients and their friends by medical practitioners are most potent factors in combating the disease.

In conclusion, we can say that Dr. Babcock's work is one of the best manuals on diseases of the lungs which we have seen. His style of writing is pleasant and rivets the attention. In addition, the printing of the book is good and the illustrations are excellent. We cordially recommend the work to our readers.

Foods and their Adulteration. By HARVEY W. WILEY, M.D., Ph.D. With 11 coloured plates and 86 other illustrations. London: J. and A. Churchill. 1907. Pp. 625. Price 21s. net.

THE American Government promises to lead the way in regard to legislation having for its object the purity of foods and food products and the protection of the public against misrepresentation and adulteration. New measures are contemplated which if carried into effect will place severe but justifiable restrictions upon many manufacturers of food products. The issue at the present moment of this work by Dr. Wiley, who is the official chemist in Washington, is therefore of particular interest. Its contents no doubt reflect the experiences which the author has gained in the course of his onerous official duties. He takes, and very properly so, a high ethical view of the question, and no doubt he has been blamed by the representatives of some trades for exacting a high ideal; doubtless also he has been stigmatised by others as one who is needlessly interfering with legitimate trade practices and, by his official influence, threatening to inflict hardships upon certain food industries. For our own part, we are confident that Dr. Wiley has acted conscientiously throughout and that he has been jealous of the public health and the public good whilst anxious to avoid unnecessary interference with trade interests. We are certain that if the governments of all civilised countries would adopt a strong attitude in regard to suppressing the manipulation of foods with objectionable

Lessons in Disinfection and Sterilisation. By F. W. ANDREWES, M.D. Oxon. Second edition. London: J. and A. Churchill. 1907. Pp. 222. Price 3*s.* 6*d.* net.—Dr. Andrewes has done well to bring out a second edition of his practical little work—an expansion of a course of lectures to the nursing staff of St. Bartholomew's Hospital, which now includes an elementary course of bacteriological instruction as well as a scheme of practical experiments illustrating the processes of disinfection and sterilisation. The book has been written from the point of view, as is stated more than once in the text, that while a short practical course in the laboratory will do far more in teaching the principles of disinfection than the reading of many treatises, the average nurse cannot be expected to take out such a course. Consequently the experimental section which illustrates the lessons in bacteriology makes no demand on any familiarity with microscopic technique, but consists of what the author terms "naked-eye bacteriology" throughout. The result is a most useful little book; indeed, we quote these following words in a prefatory letter from Professor Klein on purpose to endorse them: "Every nurse and every person who is brought in contact with the sick room will from this book be able to gather a most useful, correct, and intelligible account of the manner of preventing contagion and of neutralising and destroying contagia."

A Text-book of Plant Diseases Caused by Cryptogamic Parasites. By GEORGE MASSEE. London: Duckworth and Co. 1907. Pp. 472. Price 6*s.* net.—The author of this book is the principal assistant at the Kew Herbarium, and his knowledge of cryptogams is shown by this interesting volume to be very extensive. The aim of the book, as stated in the author's preface, "is to enable those persons directly occupied in the cultivation of plants, and with but a limited period of time available for study, to determine the nature of diseases caused by parasites of vegetable origin"; and "to apply in the most approved manner those curative and preventive methods which experience has shown to be most successful in combating the particular form of disease under consideration." The author has also aimed at showing his readers how to include in the daily routine of horticultural work precautionary measures which, without being costly, would often prevent a slight disease from assuming the proportions of an epidemic. It will be seen that the work, which to our mind succeeds very exactly in its objects, has no direct medical application; but some of the disease processes described bear a curious resemblance to pathological results in the human subject, and readers who may not be interested from any sociological or selfish point of view in the knowledge that gigantic sums are lost to this country yearly through the ravages of vegetable parasites may none the less find Mr. Massee's book very suggestive. Those who are familiar with Mr. Jonathan Hutchinson's instructive views and remarks upon plant pathology will find in Mr. Massee's book material for advancing their knowledge along a most interesting path of research.

Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature. By JOSEPH BUTLER, D.D. Edited by the Right Hon. W. E. GLADSTONE Oxford: University Press. 1907. Pp. 423. Price 1*s.*—Among many volumes of the World's Classics, the extremely valuable series of reprints which Messrs. Henry Frowde and Co. are now publishing at moderate prices, there is not one that we are more pleased to see in a cheap and convenient form than Butler's Analogy in the shape laboriously prepared by his earnest student, the famous Prime Minister of England. Butler's Analogy may be an old-fashioned work, but it remains a model of argument from its debatable premisses, and a monument of eloquent ingenuity. Mr. Gladstone, considering that the tissue of Butler's thought is closer than that of any of the ancient philosophers except perhaps Aristotle, came to the conclusion that the difficulty of mastering his ideas was seriously aggravated by want of references and cross-references, sectional divisions with their headings, and a good index. These defects he set himself to repair and the result was an edition of the great work of the famous bishop wherein it was easy for the ordinary student to find his way. It has been said that as Newton unfolded the system of nature so Butler explained the system of grace, and certainly Butler's work has always been a favourite one with scientific men, usually ready to regard theological disquisitions as the splitting of straws. Many of our readers may like to renew their acquaintance with the Analogy now that it is placed so easily within their reach.

The Health of the State. By GEORGE NEWMAN, M.D. Edin. London: Headley Brothers. 1907. Pp. 199. Price 1*s.* net.—This little book is the second volume of the Social Service Series, an issue of authoritative manuals on topics of sociological importance now appearing under the general editorship of Mr. Percy Alden, M.P., who himself wrote the volume on "Housing" with which the series commenced. Dr. Newman has only attempted to deal in plain language with some of the more important problems of public health, having regard to the fact that he is addressing a lay audience, but the complete familiarity with every detail of his subject that he possesses is very exactly shown by his knowledge of what to insert and what to omit. It is in matters of State medicine that the layman and the medical man really meet in common conclave, and it is particularly important that those citizens who desire of their free will to render social service to the State should possess adequate knowledge which they can bring to bear upon public authorities for the proper control of the health of the community. Dr. Newman, the newly elected Chief Medical Officer to the Board of Education, has been medical officer of health to the borough of Finsbury and lecturer on public health at St. Bartholomew's Hospital. He has every qualification, both as expositor and first-hand worker, for writing a manual addressed to the people at large, and we congratulate him upon the result. He is not content with recording unfortunate conditions; he is ready to suggest remedies. At the end of the chapter dealing with the hygiene of childhood, for example, he appends a list of "musts" and "shoulds" with which all medical men will agree. He says that school children *must* be fed, medically inspected, and, if mentally backward, specially instructed; he says that the elements of temperance and domestic hygiene *should* be taught in properly drained and ventilated buildings, and that neglectful parents *should* be punished. A similar directness pervades a very valuable little book.

The Birds of the British Islands. By CHARLES STONHAM, C.M.G., F.R.C.S. Eng., F.Z.S. With illustrations by LILIAN M. MEDLAND. In 20 parts. Part 7. London: E. Grant Richards. 1907. Price 7*s.* 6*d.*—The contents of the seventh part of Mr. Stonham's most interesting work include descriptions of the corvidæ—the jackdaw, the raven, the carrion crow, the hooded crow, and the rook; of the larks, the woodpeckers, the swift, the wryneck, the night-jar, the nutcracker, and several other rare or accidental visitors to our shores. As in the previous parts Mr. Stonham shows himself an excellent blend of scientific and field naturalist, while Miss Medland's illustrations continue to fulfil the sound promise of the earliest issues. She has two limitations to deal with—firstly, some birds, for example, the raven and the crow, have to be drawn to a scale reduced from life to enable their presentment to get into a page; and, secondly, the pictures are all in black and white. When these things are taken into account we consider the pictures admirable, while she has seized upon points mentioned by Mr. Stonham in the text and

MUSCATOL.

(Frank A. Rogers, 327, Oxford-street, London, W.)

Muscatol is described as a preventive of insect bites. We have tried it practically and it certainly seems to ward off the attacks of these irritating pests. Insects are a real source of trouble to sportsmen and others and the demand for a preventive is widespread. Muscatol appears to us to be a spirituous solution of certain essential oils. It is pleasant and its application is soothing.

TABLOID GINGAMINT.

(Messrs. Burroughs, Wellcome and Co., Snow Hill-buildings, London, E.C.)

This is a satisfactory formula when an effectual antacid and stomachic is indicated in the relief of certain dyspeptic symptoms. Each tabloid contains 5 grains of sodium bicarbonate, $\frac{1}{12}$th grain of ammonium bicarbonate, with gingerin, saccharin, and oil of peppermint. This combination is well known to influence favourably appetite and digestion and is of value also in relieving griping, while it excites a gentle stimulant effect.

GLENDROSTAN WHISKY.

(Alexander Mackenzie, 43, Church-street, Inverness.)

It is satisfactory to find that this whisky answers to both the test of the palate and of analysis in accordance with its description. It is a fully matured, all-malt, pot-still spirit. It is peculiarly "soft" as regards its flavour and also somewhat "dry"—characteristics which afford evidence that the spirit is thoroughly matured. The results of analysis show an amount of ethers practically equivalent to that contained in genuine brandy. Other by-products, aldehyde, furfural, and higher alcohols, were present in amounts coinciding with those invariably found in genuine old malt whisky. The colour is somewhat dark, owing doubtless to contact with the cask. The whisky conforms to the standard of genuine old all-malt whisky.

CALYX CORNFLOUR.

(H. N. Bathgate and Co., Atlantic House, College-green, Bristol.)

We have already referred to the superior quality of this cornflour but it has since been modified in an important way as a dietetic product chiefly by the addition of milk protein. The procedure may be regarded as dietetically sound since it is well known that cornflour is an excellent vehicle for protein foods. The absorption of cornflour in the intestine is very complete owing to the easy digestibility of the starch. A mixture of this digestible carbohydrate with milk protein should prove, therefore, to be a valuable food. According to our analysis the milk protein occurs to the extent of 9 per cent., which is a judicious proportion. As a rule, the quantity of protein added to foods is in excess of physiological indications. This preparation also contains 2 per cent. of calcium phosphate which is, of course, the normal mineral ingredient of cereal foods. When prepared as directed the preparation affords an agreeable food possessing a slight malty flavour due to the addition of a small quantity of malt. Our analysis was as follows: moisture, 11·90 per cent.; milk protein, 9·0 per cent.; mineral matter, 2·10 per cent.; and starch, 77·0 per cent.

INVALIDS' AND INFANTS' BISCUITS.

(S. Peters and Co., 59, Park-road, Leyton, E.)

These biscuits are well made and are prepared from nutritious materials. These include eggs, besides milk and flour. Their nutritious value is accordingly satisfactory, the protein amounting to 14·11 per cent. and the mineral matter to 1·30 per cent. Egg fat was readily extracted. The mineral matter contained an abundance of phosphate. The biscuits are very palatable and are evidently carefully baked, their spongy character being due, of course, to the disengagement of gas during fermentation.

GRAY'S TONIC.

(E. J. Reid and Co., 9, 10, and 4, Dunedin House, Basinghall-avenue, London, E.C.)

There is no secret about the formula of this preparation, while it is being introduced, it is stated, to the notice exclusively of medical men and not to that of the public. It is a combination suggested by a medical man in the United States, and is described as a combination of glycerine, gentian, taraxacum, phosphoric acid, sherry, and carminatives. The taste is pleasant and its administration is without unpleasant effect on the gastric functions. It is spoken of as a useful tonic in nervous exhaustion and general debility. It is free from iron and does not give rise to the disturbing effects of ordinary iron salts. It contains 11 per cent. of alcohol as a menstruum. The formula appears clinically to be a satisfactory one.

CRESSIDI'S CIGARETTES.

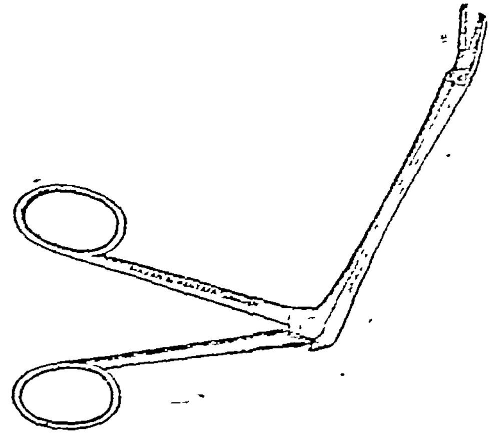
(Cressidi and Co., 115a, Queen's-road, Bayswater, London, W.)

Of a not particularly distinguished flavour, though they are very mild, these cigarettes are evidently made from a good quality Dubec leaf. The smoke is, comparatively speaking, unirritating and cool, whilst the tobacco itself is practically free from dust.

New Inventions.

A NEW PATTERN OF NASAL SCISSORS.

For the last six months I have been using a pattern of nasal scissors which has some new and, I think, useful points. The action is the same as the ordinary Grünwald's forceps but the cutting blades are placed at an obtuse angle with the shank and the cutting edges have slight saw teeth which prevent their losing grip of any hard substance. I have found them useful for removing the posterior ends of the inferior turbinates; to perform this they are passed as an ordinary Eustachian catheter, the blades opened, and then drawn over the end of the turbinate. They also can be used for removing the anterior end of the middle turbinate. They are made with the blades angled to the right or left. Messrs. Mayer and Meltzer have carried out my ideas with their usual skill and attention to detail.



Shrewsbury. C. G. RUSS WOOD, F.R.C.S. Eng.

North-East London Post-Graduate College.—The opening lecture of the winter session of the North-East London Post-Graduate College and of the North-East London Clinical Society will be given by Dr. W. Hale White at the Prince of Wales's Hospital, Tottenham, N., on Thursday, Oct. 3rd, at 4 P.M. The subject of the lecture, to which all qualified medical practitioners who are interested are invited, will be the Various Conditions causing Enlargement of the Liver.

or might be present on behalf of the employer or of the workman, or of both, the Home Office authorities would have said so in plain terms. This they have not done and it seems a little doubtful whether the language used should be construed so as to bear such a meaning. Perhaps it may give to the medical referee discretion to have present a medical practitioner or practitioners and to hear what they may have to say on either side, but it must be remembered that the Act is designed for the benefit of the working man and is not intended to favour the longest purse. The position of a workman when not a member of an organisation capable of finding funds to pay his medical adviser might be prejudiced, or might be thought to be prejudiced, if a medical man appeared on behalf of the employer before the medical referee and if at the same time the workman was not similarly supported.

◆

Poisonous Metallic Carbonyls.

A VERY interesting reaction discovered by Dr. LUDWIG MOND is that which takes place between carbon monoxide and nickel or iron. In either case a volatile compound is formed termed respectively nickel or iron carbonyl. The reaction is utilised in the recovery of metallic nickel from its ore, the carbonyl formed decomposing on heating to 150° C. into nickel and carbon monoxide. In the commercial production of nickel in this way some cases of fatal poisoning amongst the workpeople have occurred owing to the escape of the nickel-carbonyl gas. The symptoms are giddiness, dyspnœa, and vomiting, these passing off as soon as the sufferers are brought into fresh air. After from 12 to 36 hours, however, dyspnœa returns, cyanosis appears, and the temperature shows a rise. Cough with more or less blood-stained sputum eventually appears. The pulse-rate increases but not in proportion to that of respiration. Delirium frequently occurs and death in the fatal cases takes place between the fourth and eleventh days. The chief changes found post mortem are hæmorrhages in the lungs, œdema of the lungs, and hæmorrhages in the white matter of the brain. The question as to what constituent of nickel carbonyl is responsible for the toxic effects has been studied by several observers and more recently by Mr. H. W. ARMIT in the Lister Institute of Preventive Medicine, an account of his work appearing in the July number of the *Journal of Hygiene*. It is conceivable that the carbon monoxide of the nickel compound is wholly or partly responsible for the symptoms or that nickel carbonyl is absorbed as such and acts toxically, or that the nickel of the compound produces the symptoms. As an alternative view may be considered the possibility of nickel carbonyl being absorbed as such, the nickel being set free later, acting toxically in the tissues. Mr. ARMIT shows that carbon monoxide is not the toxic agent because firstly in fatal poisoning from minimal doses the actual quantity employed is insufficient when combined with the hæmoglobin to produce more than 5 per cent. of saturation with carbon monoxide and this amount is harmless. Dr. JOHN S. HALDANE has shown that in connexion with mine-gas poisoning with less than 0·1 per cent. of carbon monoxide in the air the blood does not become more than 50 per cent. saturated, so that even a prolonged exposure does not cause a complete helplessness. With 0·2 per cent. the blood will become about 67 per cent. saturated and complete helplessness, with loss of consciousness, would doubtless occur. This percentage would, of course, in the prolonged exposure finally cause death. The second argument which Mr. ARMIT gives against the theory of pure carbon monoxide poisoning is that the blood of an animal saturated to the extent of 32 per cent. with carbon monoxide loses carbon monoxide during subsequent poisoning by nickel carbonyl. Thirdly, iron carbonyl is, he says, less toxic than nickel carbonyl, although it contains more carbon monoxide. It would thus appear that the toxic effect of nickel carbonyl is not produced by the carbon monoxide present; and, further, when the quantity of nickel carbonyl vapour inhaled is only just sufficient to kill, the total available amount of carbon monoxide is insufficient to influence the course of poisoning. The next point obviously to determine was whether nickel carbonyl in contact with the fluids and tissues of the body gives rise to a toxic product of decomposition, and the investigation of this part of the problem led to very interesting results. To begin with, nickel carbonyl in the presence of air and moisture decomposes and a deposit forms which is due to the dissociation of the compound and the formation of a hydrate or carbonate of nickel. Experiment demonstrated the fact that nickel carbonyl is more soluble in blood serum than in water, and its solubility in blood itself appeared to be the same. At the same time, however, there is dissociation of the nickel carbonyl, the product of dissociation proving also to be more soluble in serum than in water. Bearing in mind the influence of serum in keeping metallic precipitates in colloidal solution it is not improbable that the dissociation product exists in serum in colloidal form. The conclusion is thus reached that first of all the poisonous properties of nickel carbonyl do not depend, as was at first supposed, on the carbon monoxide of the compound but on the nickel, and that most probably this metal is deposited as a slightly soluble compound in a very fine state of subdivision over the immense area of the respiratory surface. It would be interesting to know whether iron carbonyl gives rise in the same circumstances to a similar dissociation product which, if it be physically similar to the nickel product—that is to say, in a fine state of subdivision or in a colloidal condition—might be expected to exhibit some analogy in regard to toxic effects. Iron carbonyl, however, is reported to be less toxic than nickel carbonyl, so that it may be assumed that the former either does not give rise to a dissociation product, or that, if it does, this product does not act as a colloidal or mechanical poison.

Child Labour and Public Health.

THERE are many probably of the present generation to whom "The Song of the Shirt" constitutes a reminiscence of the reading of their early days and was even then looked upon as telling of an evil condition of things belonging to a past age of society, one which modern prosperity and modern hygienic development had rendered impossible of repetition. To such perhaps the recent exhibition of sweated industries may have been something of a revelation. It seems barely credible that in these days of sanitary inspectors and health-

Annotations.

"Ne quid nimis."

THE ANARCHICO-REGICIDE: HIS MEGALOMANIA.

"LA Monomanie Vaniteuse" or "Ambitieuse" of the older school of French alienists has now (writes an Italian contributor) been replaced by the term "Megalomania," of which, perhaps, the most typical examples are provided by Italy. A recent visit of Dr. Giuseppe Dominione to the great Manicomio Giudiziario of Montelupo in Tuscany enables that legal expert to give several illustrations in point. In a series of brilliant articles contributed to the Milanese *Secolo* he invites the medical readers to a "march past" of the criminally insane, beginning with Giovanni Passanante, the "cuoco-filosofo" (philosopher-cook) of Salerno who, in the November of 1878, attempted the life of King Humbert. His Majesty had been some ten months on the throne and in company with Queen Margherita, his little son the Prince of Naples, and his Prime Minister, Benedetto Cairoli, was making a royal progress through the capital of the ex-kingdom of the Two Sicilies when suddenly from among the cheering crowd a young man leaped on the carriage and resting one foot on the step dealt a blow at the King with a stiletto, which missed its object but penetrated the thigh of Cairoli. The wound was not fatal and both the King and Cairoli exerted themselves to save the frantic aggressor from the mob which would have given him short shrift. He was instead conducted under a strong escort to prison, whence after the usual delays he was removed to solitary confinement and thereafter to penal servitude in the "ergastolo" of Portoferraio (Island of Elba). Ten years of this life developed such signs of insanity that he was transferred to the Manicomio Giudiziario of Montelupo, where Dr. Dominione the other day found him a shrivelled old man of 57, with snow-white hair and face intersected like a map with lines of "longitude and latitude." So enfeebled that he could stand only with the aid of a stick, the "agile tiger" of 1878 responded to questions in a tremulous, scarce audible voice, hovering always round his *idée fixe* that in that year he was to be "the greatest of men," diffusing from the pedestal of his regicidal act theories that were to rehabilitate humanity. All throughout his 29 years of confinement, solitary or penal, he employed himself at every available hour in writing out his schemes for regenerating his fellow man, supplementing his manuscript with "illustrations," some of them modelled in bread or chalk or whatever material came to hand—manuscripts and illustrations alike deposited in the museum of Montelupo for the benefit of the psychological student. Among his last words to Dr. Dominione were, "I want to speak to the delegato (the sub-sheriff); I must descend the stairs ......," till cajoled by Dr. Codeluppi, the director of the Manicomio, he tottered back to the corner of his cell and threw himself sighing, if not sobbing, on his mattress. "He cannot hold out long," was whispered to Dr. Dominione as he took his leave; "after the pneumonia from which he made a poor recovery some months ago, he is declining fast." From this typical, pathetic figure of the "megalomaniac" Dr. Dominione was conducted by the director to several others, all presenting dramatically interesting traits, till they paused before the cell of Pietro Acciarito. This man—he was a youth then—was convicted of the second of the three attempts made on the life of "Humbert the Good." During the race week of the Italian Derby in April, 1897, he had ensconced himself behind a hedge to waylay the King as His Majesty was driving from Rome along the Via Appia Nuova to the grand stand, but before he could reach the carriage he was collared and arrested. Put on his trial he was passed from one prison to another, the last being the Manicomio Giudiziario at Montelupo. His mental symptoms more than justified the transfer, as Dr. Dominione discovered after a brief interview with him. The heavy bolts of the cell door having been withdrawn a furious voice demanded: "Signor Direttore, questa famosa carta, questa penna, quest' inchiostro, quand' è che me li date?" (Mr. Director, this much-talked of paper, this pen, this ink, when are you to give me them?) "Keep quiet, Pietro," was the answer; "to-morrow." The would-be regicide was a fine specimen of a young man, glossy black hair and beard forming a frame to his handsome features. "This paper," insisted Acciarito, getting more and more furious. "I will let you have it, don't doubt it," replied the director, who, turning to the visitor, remarked: "He worries over this. The sheets I give him serve only for a hundredth or thousandth protest on his part." He, too, was a would-be regenerator of society, beginning, as his brethren of the same apostolate always try to begin, by taking the life of the most conspicuous of his compatriots. Foiled in his attempt, the self-flattery of the megalomaniac sustains him even in his cell and perhaps explains his yet vigorous physique which will stand him in longer stead than his poor neighbour, Passanante's. Presently the midday bowl of pasta-soup flavoured with tomatoes was handed to him. This sufficed to break off the interview, as he retired to the corner of his cell. "His mind," says Dr. Dominione, "has already taken flight like a sparrow from its cage, but his body will make a good fight against the horrors of segregation." Another case, not, however, in Italy, though that of an Italian, may put the finishing touch to Dr. Dominione's experiences. In Switzerland Luccheni, who, in the August of 1898, stabbed the Empress of Austria as she was entering the steamboat at Geneva, is as typical a specimen of the megalomaniac as any country has yet produced. When the gratified self-esteem that had borne him elated through the trial and through the first weeks of imprisonment had died down he was found by the director of the prison in a dejected condition, in which he remained till a few questions were cautiously put to him with a view to his disclosing what confederates he might have had in his crime. The creature brightened up immediately. "Oho!" he exclaimed, "the newspapers are still talking of me!" and with these words he seemed to become another man. So pronounced a case of megalomania has, it is understood, made a deep impression on the legal mind, Swiss and Italian, counselling a different mode of procedure. No publicity; no "pomp and circumstance" of a thronged law-court; no "advertisement" of the megalomaniac by newspaper reports and pictorial illustrations. Such in future it is proposed should be the conditions under which the Passanantes, the Acciaritos, the Lucchenis should be brought to trial and carried through it. Megalomania would thus lose one of its chief attractions and incentives for the disordered minds in which it has taken root.

A CANCER EXHIBITION AT BRUSSELS.

A CANCER exhibition will be a feature of the International Surgical Congress which is to be held at Brussels in September, 1908. All objects connected with cancerous disease may be entered for exhibition—namely: (1) macroscopic or microscopic cancer specimens which are either instructive from a surgical standpoint, or of special interest on account of their localisation or method of dissemination; (2) anatomical specimens or drawings illustrating operations for cancer; (3) anatomical preparations of the lymphatic vessels and glands; (4) statistical wall-charts illustrating the frequency of primary cancer and its metastases; (5) statistical charts dealing with the spread of cancer in was admitted into hospital on May 11th, 1907. The temperature was 99·6°F., the pulse was 112, and the respirations were 40. There was no history of any wound. On May 1st the illness began with slight pain in the jaws which soon became stiff. The stiffness increased and on the sixth day he was unable to go to school. The exertion caused profuse sweating and on returning home there was stiffness of the right side, especially of the leg. On the following day, May 8th, general rigidity had set in. On admission he was remarkably rigid. He could not move his head and his jaws were tightly locked. The corners of his mouth were drawn down, his eyes were partly closed, and the risus sardonicus was present. The arms could be moved somewhat but were very stiff. The muscles of the trunk were rigid. The back was arched, the abdomen was board-like, and the legs were held immoveably. Every few minutes, especially when disturbed, he stiffened himself, muscular twitchings occurred, and he moaned and complained of abdominal pain. An attempt was made to administer ethyl chloride but in less than a minute violent spasm of the muscles of respiration and cyanosis were produced. He was revived by artificial respiration. Lumbar puncture was performed and clear cerebro-spinal fluid rose in the manometer to a height of 235 millimetres. Three cubic centimetres of a 25 per cent. solution of magnesium sulphate were injected at 3 P.M. After five minutes the neck was less rigid. In one hour distinct relaxation of the muscles had occurred. At 5 30 P M. the change was remarkable; the patient was drowsy; his neck could be freely moved; his jaws could be separated about 1·5 centimetres; his abdomen was soft, and his legs and arms were relaxed. He seemed in excellent condition and was comfortable except for a slight headache. At 1 A.M. the rigidity had partially returned and on the morning of the twelfth day, 18 hours after the injection, it had completely returned with the spasms. At 10.30 P M. lumbar puncture was performed. Only one or two drops of cerebro-spinal fluid, which did not seem to be under any pressure, were obtained; three and a half cubic centimetres of the solution of magnesium sulphate were injected. At 11 P.M. the neck was less rigid and the knees could be slightly flexed. The patient felt drowsy but more comfortable. Relaxation was fairly complete at 12 15 A M. On the fifteenth day the rigidity gradually returned and at 8.15 P.M. lumbar puncture was performed. The cerebro-spinal fluid rose 160 millimetres in the manometer. About three cubic centimetres were withdrawn and four cubic centimetres of the solution were injected, with the same result as before. The rigidity returned in less degree and after the seventeenth day it gradually diminished. Recovery ensued.

THE RECENT CONFERENCE ON HYGIENE AND TEMPERANCE.

IT will be remembered that on St. George's Day, April 23rd, of the present year advantage was taken of the visit to the mother country of the colonial Premiers to hold a conference for the purpose of obtaining information as to the steps that had already been taken in the outlying parts of the empire to introduce the teaching of hygiene and temperance in educational establishments. The conference was convened by a composite committee consisting of representatives of the hygiene and temperance committee of the medical profession and of the health committee of the British Medical Association. The Earl of Elgin, Secretary for the Colonies, lent his support and Lord Strathcona and Mount Royal, the veteran High Commissioner for Canada, Sir John Gorst, recently Minister for Education, and Sir John Cockburn acted as chairmen. Many prominent colonial citizens were also present and educational authorities of the highest standing, including officially appointed delegates from the various colonies and European states, took an active part in the discussions. Among the members of the medical profession who either contributed papers or took part in the discussions were Sir Lauder Brunton, Sir William Collins, Sir Victor Horsley, Sir Philip S. Jones, Mr. James Cantlie, Dr. Robert Dinnet (Paris), Dr. Foveau de Courmelles (Paris), Mr. A. Pearce Gould, Dr. Helminius Seppälä (Scandinavia), and Professor G. Sims Woodhead. The proceedings of the conference, which make a valuable contribution to educational literature, have now been issued in the form of a little book of 129 pages[1] at a price which puts it within the reach of everyone who is interested in the subject of education. Mr. Pearce Gould contributes a preface in which incidentally he calls attention to the system initiated by Mr. Chamberlain when Secretary for the Colonies of adapting teaching to the special and peculiar needs of the peoples dwelling in varying climates and exposed to differing epidemic and endemic scourges. "Naked African children," he says, "are now taught how to protect themselves from malaria, not by obedience to cut-and dried rules, but by the actual observation of the facts which the most advanced science has revealed. If the methods of science are not inappropriate for the aborigines of Africa they cannot be unsuitable for the far more developed children of the villages and towns and even of the slums of Great Britain. ...... We must ask ourselves what are the physical evils our population has most to dread and must teach them all that the most exact science can tell them. ...... We must not be afraid of adopting the *methods* of science in imparting the *lessons* of science." One of the resolutions passed by the conference was to the effect that a medical department should be instituted in the Board of Education and it is signally felicitous that the proceedings of the conference should have been published in book form almost on the eve of the announcement that such a department had been formed.

BIER'S TREATMENT OF TUBERCULOUS SINUSES.

THE treatment of inflammation, acute and chronic, by the induction of passive hyperæmia, introduced by Professor Bier, has not been much used in this country though it has given remarkable results. In the limbs passive congestion is produced by the application of an elastic bandage above the inflammatory area. But on the trunk and head this method is obviously inapplicable. For the treatment of inflammation in the latter localities Professor Bier's assistant, Dr. R. Klapp, has introduced the method of producing hyperæmia by means of glasses attached to small indiarubber bags (like cupping glasses). A partial vacuum is produced by applying the glass with the bag compressed. The part to which the glass is applied projects and becomes of a reddish-blue colour. In the *Boston Medical and Surgical Journal* of June 6th, Dr. J. W. Sever has reported good results from this treatment of tuberculous sinuses due to bone disease which are proverbially slow in healing. Drainage is difficult and requires assistance. By cup suction this indication is fulfilled and, moreover, hyperæmia is produced which stimulates the healing process. Dr. Sever uses small glass cups about 1¼ inches in diameter and 2 inches high, the top of which is tapered to fit a rubber tube connected with a rubber bulb. The cup is applied with the bulb compressed, creating a vacuum sufficient to maintain the cup in position. In places where the elastic bandage could be applied, such as the knee, ankle, elbow, or wrist, this is also used. The treatment was carried out for one hour daily. At no time was the suction strong enough to cause pain. Every few minutes the cups were removed to
